by a young lady against Mr. WILLIAM BEDELL BENISON, surgeon, of Moseley and King's Heath, near Birmingham, for alleged slander, the damages being laid at £500. The slander consisted in attributing some symptoms in the young lady to having contracted contagious disease from her betrothed, who for some time had laboured under a suspicious sore of the lip. Mr. BENISON had warned the young lady on this subject, and did not charge her with anything more culpable or criminal than having possibly been a party to a kiss, which the most severe young ladies, under such circumstances, might too readily allow. No fault was found with the opinion or treatment of Mr. BENISON for six months, and not then till his account was sent in, which included not only charges for attendance, but for kindly loans which he had granted in circumstances of exigency to the plaintiff's family. The jury, without much deliberation, gave a verdict for the defendant. Medicine is a profession so difficult, and its services are so valuable, that gratitude should cover even occasional errors or shortcomings of treatment. This is so with many patients. But how different here, where ordinary charges are disputed and become the occasion of litigation, which is expected at least to injure the medical man, even if he gains a verdict. We are not without hope that the very frequency of these cases will bring about some legal protection to medical men. Meantime the sympathy of the profession and of the public will be with those practitioners who in the very discharge of their duty and vindication of their rights incur the displeasure of unreasonable or unscrupulous patients.

THE subject of coma—a condition which is induced by so many and varied circumstances—has always been open to much speculation and discussion; but it has seldom received more apt and adequate treatment than Dr. MERCIER supplies in the January number of *Brain*. His paper is a thoroughly scientific exposition, and the conclusions at which he arrives are valuable both for their suggestiveness and for the light they throw upon the higher cerebral functions. He accepts, with one slight modification, Mr. SAVORY's definition of coma, as a "state of insensibility from which the patient cannot be completely aroused, together with a tendency to death, chiefly by asphyxia"; the modification being the substitution of the phrase "evidence of defect of consciousness" for the term "insensibility," as being more correctly descriptive of a state in which it is impossible to determine whether or not consciousness is absolutely lost. He points out that the failure of respiratory power is due to the same condition of powerlessness and loss of muscular tone that pervade the whole organism in the comatose state. The skin is relaxed and flaccid, the pulse is full and soft, the bladder contracts sluggishly, the pupils may have lost all power of contraction, and all the limbs are paralysed, the muscles being quite flaccid. The comatose patient is not inert because he is unconscious, but because he is actually paralysed. Indeed the cardiac muscle alone does not share in this universal paresis. From this condition of complete coma to that pre-comatose period marked by the slightest mental confusion and bodily weakness there are all gradations—as may be seen, for example, in alcoholic poisoning, of which an excellent sketch is given. The phenomena of drunkenness in all its stages exhibit an unbroken chain of gradually deepening lesion of the higher cerebral functions, which enable us to trace the relations of the condition we call coma to the slight perturbations and deviations from the normal condition that mark the earliest changes due to the action of the poison on the brain. As Dr. HUGHLINGS JACKSON has pointed out, the paralysis is first that of a loss of movements rather than of motion; the more elaborate actions go before the coarser; the breathing fails before the heart, and the accessory parts of the breathing apparatus fail before the fundamental. It consists in "a long process of degradation, the last point of attack being the heart, and the penultimate the breathing." Incidentally Dr. MERCIER indicates a pathognomonic sign of true coma, which depends on this loss of muscular control, and that is the movement of the eyes independently of one another.

As with the bodily so with the mental functions. The progress of coma is marked in the one as in the other by a gradually increasing enfeeblement. At first there is difficulty in performing delicate mental operations, and then inability for any coherent thought, and, lastly, evidence of loss of consciousness; no response to impressions from without, no evidence of response to impressions from within. And this coincides with the relaxation of muscular tone, the ataxia passing into paralysis; so that the power to execute voluntary movement fails *pari passu* with the failing intelligence, and suggests overwhelmingly the inference that both mental and bodily defect are due to the same lesion. And, it is pointed out, the whole organism is affected—evidence again, that in the highest centres of the brain we have to do not with any specialised and circumscribed areas of "localisation," but with a region where the various parts of the body are all represented in some degree, the region of consciousness and of the organism as a whole. Dr. MERCIER implies that in the modern doctrine of "nerve centres" we run a risk of losing sight of this fact or principle, that the whole organism is represented, and therefore to a certain extent controlled and knit together through the highest nerve centres—a principle which is so clearly manifested in the phenomena of coma, and just as clearly in the phenomena of insanity. For insanity is linked with defects in the nutrition of the body; it runs its course, both as regards mental faculties and bodily functions, in the same direction and with the same pathological sequence as does coma, in which it often finally terminates. But if coma be a form of insanity it is a "fulminant" form; and if insanity be expressed in the terms of coma it would be that it is coma long drawn out. We are not aware that this ingenious parallel has ever been advanced before, but we cannot help being struck with its feasibility, and commend it to the attention of the alienist. The underlying principle in Dr. MERCIER'S argument is that the higher brain centres, where consciousness is aroused by impressions from within and without, and where the will is born of intelligence, and action expresses the response of the conscious will to the environment,—that there, where all the bodily functions must be represented, is the seat of the lesion that suddenly or gradually breaks the chain between the individual organism and its surroundings, and may profoundly affect those functions which, under the control of the nervous system, are essential to the

Digitized by Google

life of the organism. Possibly—nay, we might say probably—this region is conterminous only with the whole of the cerebral cortex; but this does not detract from the suggestiveness or truth of the proposition that "whether in origin, or in cause, or in termination, coma and insanity are pathologically and symptomatically identical, and the only important difference between them is the difference in duration." They each illustrate the law of Dissolution.

Annotations.

"Ne quid nimis."

THE REAL INTERPRETATION OF THE NEW ARMY WARRANT.

WHEN the Royal Warrant of January 1st was promulgated we took a considerable amount of trouble to ascertain whether it would affect the Medical Officers, and we came to the conclusion that, except as regards a step of honorary rank on retirement, it would not affect them in any way whatever. It would appear, however, that some other persons have arrived at a different opinion, and last week a medical contemporary published a leader denouncing the military authorities, and advising the professors and teachers in the medical schools to recommend their pupils to hold back from entering the Service. And upon what has this advice been founded? On the abolition of the word "relative" in describing the position of the medical officers in relation to the so-called combatant officers. But a careful examination of the Warrant satisfies us that nothing either injurious to the prospects or derogatory to the position of the officers of the medical staff is intended or effected by this change; for in paragraph 125*a* it is distinctly laid down that "officers of departments of our army, not having honorary rank, shall rank as follows for purposes of precedence, pensions for wounds, pensions to widows, and compassionate allowances to children: With Major-General, Director-General Army Medical Department, and surgeon-general; with colonel, deputy surgeon-general; with lieutenant-colonel, brigade-surgeon, surgeon-major after twenty-years' service, or under twenty years' service if promoted for distinguished service in the field; with major, surgeon-major under twenty years' service, if not promoted for distinguished service in the field; with captain, surgeon; with lieutenant, surgeon on probation." If to rank with certain grades of officers be not relative rank, though the adjective is not employed, we confess that we do not know what is; they are, in fact, synonymous. The term "relative rank" was dropped, we believe, because it was found to operate unjustly in certain cases among the combatant officers, but it can have no effect upon the medical staff, whose position will in no way be altered by the change of terms. The status of medical officers is assured to them by their respective commissions and the Royal Warrants. They have never had commissions conferring on them military rank, but their title to take rank with the different military grades is conferred on and secured to them by the Warrants. We cannot but regret that such a recommendation as the one we have alluded to should be made, when careful inquiry and a study of the Warrant itself would have shown that the grounds on which it is based were wholly misconceived. We trust the professors and teachers of the medical schools will investigate this matter for themselves. We claim to have fought the battle of the medical department when it was unjustly treated, and we are quite prepared to do so again should occasion arise. But we are satisfied that there is nothing in this Warrant detrimental to the best interests of the medical officers.

TEACHING UNIVERSITY FOR LONDON.

THE report of Lord Justice Fry's Committee will be presented to the Senate of the University of London at an early date, and will then be referred to Convocation at the annual meeting in May, unless a special meeting be summoned. The reforms which will be recommended will probably include the direct representation of University and King's Colleges on the Senate, boards of studies composed of teachers and former examiners, and an increased representation of Convocation. None of these changes have a direct bearing on the organisation of teaching in London for London students only; for the present University must consider its candidates throughout the country, indeed throughout the empire. It can hardly be expected to meet the demands of those who are promoting a teaching university for London. We understand that the Councils of University and King's Colleges will have brought before them for consideration a proposal that they should unite to form Arts and Science Faculties, and should take means to approach the Royal Colleges as the Faculty of Medicine, so that they may apply to the Crown conjointly for a Charter. If power be reserved for the admission of further suitable institutions, the views of those who prefer an academical to a professional degree will be carried out.

METSCHNIKOFF ON PHAGOCYTES.

THE suggestive doctrine that cells and bacteria are opposed to one another in a struggle for existence within the body based upon the remarkable property possessed by leucocytes of devouring foreign material in contact with them, and employed to explain the phenomena of inflammation, the formation of giant cells, and of specific neoplasms, as well as to account for immunity after inoculation, has been criticised on the one hand and staunchly supported on the other. Professor Metschnikoff—whose beautiful researches upon the behaviour of the cells of Daphnia to the spore disease that attacks this entomostracous organism formed the basis of this doctrine—returns to the subject in the last issue of Virchow's *Archiv* (Band 107, Heft 2) in an article upon the "strife between cells and the cocci of erysipelas." He declares that Fehleisen's observations upon the minute anatomy of cutaneous erysipelas harmonise with the theory of phagocytes. The spreading margin of an erysipelatous patch can be differentiated into three zones: a peripheral, in which the lymphatic spaces are filled with the streptococcus in a state of active growth; a middle, exhibiting inflammatory reaction in abundance of leucocytes between the masses of cocci; and an internal, in which cocci are conspicuous by their absence. Metschnikoff examined several cases: some fatal; others, which recovered, with the view of testing the truth of his surmise that recovery from erysipelas is due to the destruction of the microbe by the phagocyte. In the one case, of fatal gangrenous erysipelas, he found a few disintegrating leucocytes, and an abundance of cocci; in the other, where recovery took place, leucocytes were seen filled with cocci or their débris; and transitional states could be traced between these extremes in specimens derived from other cases. The inference he gathers is that in the fatal cases the streptococci gain the mastery from defective inflammatory reaction. Besides the small free leucocyte, he assigns similar properties to larger cells, derived from the fixed connective tissue elements in the subcutaneous tissue. The former he terms *microphagi*, the latter *macrophagi*, and he notes an important difference in the function of these two elements. In the subcutaneous tissue in erysipelas he finds macrophagi which do not consume the micrococci. That office is confined to the microphagi, whereas it appears to be the duty of the larger elements to consume the débris of the dead and dying leucocytes. The macrophagi therefore perform the useful

Digitized by Google

function of clearing the battle-field of the slain leucocytes; and they therefore increase in size and number in proportion as the strife between the microphagi and streptococci diminishes. It reads almost like a romance, this account of the mimic warfare carried on to the death between the invading microbe and the defending leucocyte; and yet the phenomena of local infection, inflammatory reaction, resolution, and absorption of the inflammatory products, can all be expressed in the terms of streptococcus, microphage, and macrophage. Other factors, it is admitted, may be at work—such as pyrexia—but Professor Metschnikoff holds to the foregoing as a most probable explanation of the local phenomena. In asserting this, he has to meet the arguments adduced by Baumgarten and others, especially with reference to the fact that in many infective diseases bacteria are found within leucocytes without any variation from the fatality exhibited, and also the fact that experimental injections into the blood of bacteria do not lead to the consumption of the latter by phagocytes. However, he meets these and other objections, and declares that Cohnheim's dictum "no inflammation without bloodvessels" must be changed into "no inflammation without phagocytes." The doctrine is attractive, and is deserving of further study; but it cannot be said to be established, or as yet far removed from the stage of probability.

THE PORT OF LONDON.

IN his report for the second half of 1886 Dr. Collingridge is able to show an exceptionally clean bill of health as regards shipping entering the port of London, and also an excellent amount of work, often involving structural alterations, which tends to a steady improvement in the sanitary state of the vessels. The metropolitan sewage question still causes much difficulty, for though the precipitation process now being experimented with appears to answer fairly well in cold weather, when the nuisance is always at a minimum, yet when hot weather supervenes the stench and inconvenience are as great as ever. The regulations now in force as to the disinfection of the clothing of seamen who have died abroad of infectious diseases are fully answering their purpose, and in this way another source of danger to the country has been successfully dealt with. Only one cholera-infected vessel entered the port during the year. This was the *Rialto*, which arrived at Gravesend on November 4th, having had three deaths from cholera and one from dysentery on board, the cholera deaths occurring from four to eight days after leaving Calcutta. All the crew being found on examination to be healthy, the vessel, after certain precautionary measures, was given free pratique. Inspection of canal boats is carefully carried out, and already these boats are found to carry fewer persons on board than they are certified for. The port sanitary hospital was successfully used during the half-year for the isolation of cases of infectious disease found in the port.

INHERITED PHTHISIS.

PROFESSOR FIRKET (*Revue de Méd.*, Jan. 1887), writing upon the subject of heredity in tuberculosis, points out certain difficulties in the acceptance of the doctrine of direct transmission from parent to offspring. Such transmission may conceivably take place before conception, the tubercular bacilli being associated with the sperm or germ—a purely hypothetical idea—or through the medium of the placenta, and therefore solely by the maternal blood. He contends that there is not such positive proof of infection of the maternal blood, and thereby of transmission of disease to the fœtus in the case of tuberculosis, as there is in anthrax or syphilis, or variola and other affections. Moreover, he shows that in ordinary phthisis fully one-half of the cases do not exhibit, in the presence of remote secondary lesions, evidence of blood infection. It is for the most part a local disease of the lung, and such secondary lesions as do occur may be explained in many cases apart from general blood contamination. How different, it may be said, from the old notion of phthisis! But the fact of the lung being the primary seat of tubercular disease in inherited cases is almost conclusive against the congenital theory; for if the fœtus were infected through the blood, the chances are that the lungs would not suffer more than any other organ.

THE METROPOLITAN ASYLUMS BOARD.

THE managers of the Asylums Board had under their consideration on Saturday a proposal of the General Purposes Committee to make the services of their principal officers available at any infectious establishment under the managers' control. This is obviously required in the interests of the public service, for the experience of past years has amply shown the necessity for the managers to possess the power of utilising the services of their officers in such manner as the requirements of the moment may dictate. It was resolved that the Local Government Board should be requested to make an amending order for this purpose. The change will doubtless cause expense and inconvenience to some of the older officers, but this point will, we trust, meet with consideration at the hands of the Metropolitan Asylums Board, and we shall gladly see the officers manifest a readiness to comply with a change which is needed to enable the Board more efficiently to perform their duties. A second and more important point is embodied in the report of the same committee, who recommend that application be made to the Local Government Board to obtain authority for the managers to remove, at the request of duly qualified registered medical practitioners, all persons, whether paupers or not, who suffer from fever or small-pox who desire such removal. Sir Edmund Currie moved the adoption of this recommendation, which was agreed to unanimously, and which we trust will meet with the approval of the Local Government Board. There is no reason why the admirable ambulance service of the Metropolitan Asylums Board should not be made available for the use of the general public.

THE MEDICAL PROFESSION AND THE CENTENARY OF THE UNITED STATES.

THE *Journal of the American Medical Association* points out an interesting coincidence—viz., that the International Medical Congress at Washington will be held in the very month which will mark the centenary of the present constitution of the government of the United States. The journal suggests for answer the following question—What progress has medicine and medical organisation made under such a form of government? It suggests part of the reply. When the century began there was but one organised medical college in actual operation in the entire country, having much less than a hundred students and granting less than a dozen diplomas annually. State medical societies existed only in New Jersey and Massachusetts, and there was not a single medical periodical. Such was the state of matters in 1777. But in the present year there are more than 100 organised medical colleges, educating over 10,000 students, and granting 3000 or 4000 medical diplomas annually. There are active State medical societies in every State and inhabited territory, all represented in one National Association, and 100 medical periodicals. This is a great growth, and one on the whole greatly creditable to the States. No doubt, according to our standard, the growth seems excessive and uncontrolled. There are too many colleges, and they give

Digitized by Google

too many diplomas—that is, the colleges give the diplomas too easily. But in a young democracy one man is apt to consider himself as good as another, and it is at any rate something to have it recognised that men must undergo systematic education and have their education tested. Law and public intelligence will still further define the tests to be applied in the interest of the health of the people, which is only another word for the good of the Republic.

HEALTH-SEEKERS ABROAD.

IF it be the fact, as many—Professor Huxley among other philosophic scientists—think, that earthquakes are caused rather by the shrinking of the earth's crust upon the cooling mass within, than by special convulsions set up by the sudden inrush of water through fissures into the midst of subterranean fires, it is inevitable that these phenomena should recur with certain intervals, and, which is more to the point, it is at least probable that the first crack will be followed by others, while it can be by no means certain that subsidence will not follow either suddenly or gradually upon any contraction so considerable as to cause an extensive disturbance of the surface. If the shaking, and perhaps rupture, of the outer crust were simply due to an accidental outburst of steam among the lower strata, there would be nothing to say except that what has occurred once may of course occur again; but if progressive shrinking is taking place, it can scarcely happen that a crust which is anything but homogeneous should not break away and fall in as it contracts. We know that the whole of the Riviera consists of a thin crust resting almost loosely on an irregular bed of rocks; and it is reasonable to anticipate that, while from time to time there will be earthquakes in that region, sooner or later great and widespread settlings will be effected, with more or less damage to the structures on the surface. These are the probabilities, and it is desirable that they should be recognised by those who frequent the health-resorts of the district, and particularly by those who build houses for their own occupation or the use of visitors. We are by no means sure that the very solid edifices extolled and desired in the districts recently disturbed are really the most suitable. It is quite true that the stronger buildings have escaped serious damage in certain localities, but this is perhaps more directly due to their position than to the resisting power of the structures themselves, or of the materials employed. It is not probable that any erection could offer greater resistance than the rocks, which have in some places been disturbed. Prudence would point to the expediency of constructing houses in the Riviera so that they shall rest upon the ground, rather than form part of it, and be self-contained in their stability. We fear it must be assumed that this district will henceforward need to be regarded as one in which movements of the earth's crust, and probably subsidences, are likely to occur. The fate of those who have visited the Riviera in search of health and had their nerves tried by the shock of these recent earthquakes is greatly to be commiserated. As regards the danger to life and limb actually involved, calculated on the bases of accident all the world over, the risk has not been much greater than that which would have been incurred elsewhere, whether on land or by sea; but there can be no question that the nervous shock has been considerable, and, although the Riviera cannot be correctly classed as a distinctly "volcanic" district it is a question whether it ought not to be considered an unsuitable place of residence or prolonged sojourn for those who are easily impressed or excitable. If the immediate effect of the experience of the last few weeks should be to make health-seekers and their advisers think more of the almost inexhaustible varieties of climate, atmosphere, and surroundings generally, which are obtainable within the ries of the United Kingdom, good may come out of evil. It is much to be regretted, we think, that the resources of Ireland, Scotland, and Wales, with the various well-known, and less well-known, parts of England itself, should be so persistently neglected as they are for health-resorts abroad, which are neither so salubrious, nor, but for the false glamour thrown over them, so attractive. It must be confessed that the medical profession has much to answer for on this score. To the recommendation of English physicians these continental resorts mainly owe their reputation. Let us turn our attention to the development of home resources, and our patients will be not less benefited, and decidedly exposed to fewer perils.

THE RIVER LEA.

LAST week an important conference was held at the Hackney Town Hall to consider the steps which should be taken to secure the future preservation of the purity of the river Lea. It will be recollected that the Act of Parliament which was procured as a temporary measure will shortly expire, and we may anticipate that the Lea will revert to its former condition, unless means be taken to prevent sewage effluents draining into it. The adoption of a scheme for the drainage of the whole valley of the Lea is the only effectual method of disposing of this question, but the cost will no doubt be considerable. Sir Guyer Hunter pointed out that it was necessary that delegates from each authority concerned should meet together, and determine the best method of dealing with the subject, and finally a resolution was passed calling upon the local authorities to appoint a joint committee with a view to preparing evidence to submit to a Committee of the House of Commons.

MORE MIND, MORE MADNESS.

IT is in no way surprising that insanity should seem to increase in races or classes which are being intellectually stimulated by education. There is always in every community a proportion of brains which, being brought into action, will break down. This proportion doubtless diminishes as the community is elevated, and in a very few generations the result of culture may—probably will—be to develop a better stock, looking upon the people as a whole; but at the outset of the educationary process, and in the generation first taught, the immediate result must be a considerable number of wreckings. This general principle is applicable to all races, peoples, and classes, and it explains why the first effect of trying to elevate the negroes has been to produce an apparent increase of insanity among them.

THE PREVENTION OF ANTHRAX.

THE recognition of the danger of contagion in anthrax has at length been officially made by the Agricultural Department of the Privy Council Office, in a notice just issued upon the danger of handling carcases of animals dead of anthrax. The notice is brief and to the point. It cites the fact that "several cases of serious and sometimes of fatal infection have occurred in persons who have been employed in cutting up carcases of animals dead of anthrax, and it is important that the public should be made aware of this source of danger to human life." The notice goes on to warn any person having abrasions, however slight, on their hands or arms from handling any carcases of animals which have been the subjects of this disease, or of "dealing with fodder, litter, manure, or other things which may be contaminated with the blood of diseased animals"; and it concludes with the recommendation that such carcases "should be buried entire, without being skinned or cut, and be well covered with quicklime and not less than six feet of earth.

Digitized by Google

We trust that this advice will be widely followed, and that, as a result, we may hear less of cases of this highly malignant disease among the members of the community who have to do with animals liable to infection. There is no reason why, with suitable precautions, a disease the nature of which is so fully known should ever be allowed to be transmitted to human beings.

THE LATE PROFESSOR SCHROEDER.

AT the opening of the sitting of the Berlin Medical Society on the 9th February, the President, Professor Virchow, alluded to the loss sustained by the University and the Medical and Gynæcological Societies. In compliance with the wish of members, he gave details of the post-mortem examination, which showed that death had been caused by the rupture into the lateral ventricle of an abscess situated in the white substance of the brain near the posterior part of the fornix. The abscess was old and encapsuled, and the pus within the ventricle was enclosed within a fibrinous layer, which formed a membrane at first sight resembling a hydatid. The right thalamus was completely flattened by this. Between the root of the right lung and its base there was a mass of tough fibrous tissue enclosing a small pus-containing cavity which communicated by a narrow channel with the œsophagus. There were also scattered foci within the fibrous mass, one of which contained much pigment and cholesterine—a kind of focus, Professor Virchow observed, which he had never before met with in similar conditions. The lungs were perfectly normal and free from adhesions. There was no trace of tubercle. The cause of the cerebral abscess was difficult to solve. Five years ago Schroeder had a severe illness, which he attributed to septic infection leading to conjunctivitis and pneumonia. He himself thought the conjunctivitis was diphtheritic, but Professor Schweigger did not take that view, and it is scarcely conceivable that any connexion existed between the conjunctivitis and the abscess. It is possible that the old lesion in the mediastinum might have been the starting-point of the cerebral abscess, the contents of which indicated that it could hardly have existed for more than a year.

NEW TREATMENT FOR PHTHISIS.

A NEW method of treating phthisis has been proposed, but apparently as yet but slightly tried, by Professor Kremianski, who read a paper on the subject at the recent Moscow Medical Congress, which provoked a good deal of discussion. The idea is based, firstly, on the fatal effect of the most dilute solution of aniline on Koch's bacillus, and, secondly, on the fact that aniline seems to be but slightly, if at all, poisonous to the human body. Professor Kremianski proposes to introduce aniline into the lungs, and, indeed, the circulation generally, by inhalation, so that the phthisis bacilli should be bathed in a very dilute solution of aniline, wherever they may be. This, he thinks, would kill them, and render even pulmonary cavities free from bacilli, so bringing them into the condition of healthy granulating ulcers, which may be expected to cicatrise. A committee has been appointed, including Professors Subbotin and Ostroumoff, who expressed themselves at the meeting as strongly opposed to the plan, for the purpose of observing Professor Kremianski's proposed experiments in one of the Moscow hospitals. Two cases in which the aniline treatment had been successfully tried were detailed. A lad of eighteen, who had undoubted phthisis, was ordered a four-drop dose of aniline (but took by mistake three times the proper quantity) combined with nux vomica, mint water, and antifebrin, his diet being good, including dried meat, kvas, and oranges. He was also given inhalations of atomised aniline. A remarkable change took place almost immediately, all the râles disappearing; his temperature, respiration, and pulse becoming normal. His skin, however, assumed a slightly blue tinge, but whether this was as permanent as the cure is represented to have been is not stated. The second case was a complicated one, there being tubercular peritonitis and meningitis, together with typhoid fever, present at the same time as pulmonary phthisis. Aniline inhalations, washing out the pulmonary cavities with corrosive sublimate and antifebrin, were employed, together with a special acid diet, as in the other case. Here, too, the results are said to have been remarkably good, the bacilli disappearing from the sputum, and the patient regaining his health entirely. No mention is made in the abstract published by the *Vrach* of any change of colour in this patient's skin. Amongst the various replies that were made to Professor Kremianski, Dr. Zakrzhevski, of Helsingfors, remarked that, admitting the facts as stated, still there was nothing to show that the aniline had been the cause of the cures. He himself had had surprisingly good results in phthisical cases, the disease becoming completely arrested by simply giving increased nourishment and prescribing antipyrin.

CHOLERA INTELLIGENCE.

THE announcement which has been received through the Colonial Office, to the effect that vessels are not admitted into Malta from Sicily on account of the occurrence of cholera at Catania, reminds as again that the seeds of this disease still lie scattered about in different parts of Europe. Catania is a very ancient town on the east coast of Sicily at the foot of the most southern offsets of Etna, and has a population of some 60,000. As a port its trade is not what it formerly was, owing to the obstruction offered to the entrance of vessels by remains of lava floods; but it ranks as one of the foremost cities in the island, and the possibility of extension of cholera in it must be viewed with considerable apprehension. No further news has been received as to cholera in Hungary, but the absence of news, for even long periods, has been shown on former occasions not to indicate absence of the disease. The news from South America is also very intermitting, but the disease is still prevalent from the neighbourhood of the River Plate on the east to the coast of Chili on the west.

THE HOME FOR LOST DOGS AND HYDROPHOBIA.

THE annual meeting of the Temporary Home for Lost and Starving Dogs, Battersea, was held on Feb. 28th at Jermyn-street, the Earl of Onslow in the chair. In the course of his remarks, when moving the adoption of the report, the chairman said:—

"The effect of the restrictions had been to sweep away from the streets of London a very large number of homeless curs, but how had it affected the terrible disease of rabies and hydrophobia? He ventured to say that, although the returns showed that in London rabies had been almost annihilated, the mere precaution of ordering that dogs within a certain given area should be muzzled was not in itself sufficient to stamp out the disease. The only way would be to treat rabies somewhat in the same manner as the Privy Council treated other infectious diseases affecting animals and to proscribe certain circles in which the infection existed, forbidding that migration in or out of such circles should take place without the permission of a properly constituted authority."

These remarks were received with cheers and, coming from one who is well known to be personally interested in many ways in dogs, will, we trust, calm the hypersensitive feelings of some dog-owners, who seem to regard hydrophobia as, if not a myth, a muzzle-created and artificially induced disease. We give every credit to them for

Digitized by Google

their affection for our four-footed companions, of which we cannot, however, allow them the monopoly; but when a most terrible disease can be stamped out by restrictive measures, sentiment must not be permitted to run riot. We trust the Dog's Home will meet with the support it undeniably deserves.

CATALEPSY IN A MOTHER AND CHILD.

DR. VAN SCHOOT discusses in a Dutch medical journal a case of convulsive seizures of a peculiar kind in a woman in the seventh month of pregnancy. When he first saw her she was motionless, her face being cyanotic, but her temperature, respiration, and pulse normal. She was quite unconscious, and the slightly dilated pupils did not react to light. The arms were flexed at right angles, requiring some force to move the forearms. By means of chloroform all the contracted muscles relaxed, and some hours' sleep was obtained. Afterwards she remembered nothing of the fit, but she stated that all movements of the fœtus seemed to have ceased, and no heart sounds could be detected. These attacks were repeated frequently for a fortnight, the urine being quite normal all the time. Large doses of bromide were given without effect, but some amelioration was produced by sulphate of atropine. Latterly the attacks were associated with considerable movements of the abdominal muscles. Some temporary benefit was obtained by subcutaneous injections of pilocarpine. At the conclusion of a fortnight from the first attack labour came on, a female child being born alive, which, however, died in a week's time, after repeated convulsions similar to those affecting the mother. The mother had no attack till the fifth day (the same day that the child's first attack occurred). After this there was only one more attack two days later, complete recovery ultimately taking place. The author, referring to the diagnosis, is disposed to exclude eclampsia, because, although there were clonic contractions of the abdominal muscles, the main spasm—indeed, at first the only kind of spasm—was tonic. The entire absence of albuminuria, too, tends to exclude eclampsia. Again, epilepsy may be excluded, as after the tonic no clonic spasms occurred, and as the limbs remained fixed in a certain position for one or two hours. He therefore considers that the attacks were of a cataleptic nature, both in the mother and child.

POISONOUS CHEESE.

IN this country cases of cheese-poisoning are rare, and in France, where cheese is largely consumed, they are all but unknown. But, according to Dr. Victor C. Vaughan, of the Michagan State Board of Health, the annual number of such instances in the United States must be several hundred, if it does not reach a thousand. In Germany cheese-poisoning is also frequent. The symptoms generally include dryness of the throat, nausea, vomiting, diarrhœa, nervous prostration, headache, and sometimes double vision. As a rule, recovery takes place. Recently Dr. Vaughan has given a good deal of attention to discovering the cause of cheese-poisoning, and he has received help from the manufacturers whose produce has brought about symptoms of poisoning. Amongst the manufacturers there would appear to be entire ignorance as to the cause, and such suggestions as they have been able to make, including the consumption by the cows of poisonous plants, are not borne out on investigation. From the freshly cut surface of poisonous cheeses there exude, as a rule, drops of a watery, slightly opalescent fluid, which have been found to redden blue litmus paper instantly and intensely; and Dr. Vaughan is of opinion that this should always be regarded as an element of suspicion in a cheese. Micrococci are also found in the fluid in question; but, according to Dr. Sternberg, [illegible] as yet no evidence that these micrococci are directly related to the poisonous properties of the cheese. There are, however, substantial grounds for believing that the poison is a chemical one, and it is by no means impossible that it may be generated by bacterial growth. Dr. Vaughan, in making and drying an alcoholic extract of poisonous cheese, procured a residue consisting of a fatty mass, which, on being eaten by himself, produced symptoms closely allied to those above described; but the poison itself was not sufficiently eliminated. The best results were obtained by rendering an aqueous extract of the cheese alkaline with potassium hydrate, then extracting with ether; needle-shaped crystals being ultimately separated. On placing a small piece of one of these on the end of the tongue, a sharp burning sensation, together with a sense of sickening, was soon followed by dryness and constriction. A drop of the fluid from which the crystals were ultimately extracted produced, in addition, griping pains in the bowels, followed by one or more diarrhœal discharges. Ultimate analysis of the poison has not yet been practicable, owing to the difficulty of procuring it in sufficient amount. But Dr. Vaughan places it, for the moment, amongst the ptomaines which originate in organic substances undergoing putrefactive changes. As the putrefactive changes in the milk are due to the growth of minute organisms, the introduction of these organisms into the milk may lead to the formation of the ptomaine. The practical suggestions which, so far, are the outcome of Dr. Vaughan's investigation are, firstly, more care in the inspection and cleansing of the milk-cans used in the manufacture of cheese; and, secondly, increased care as to the cows themselves, and this because where cows are kept in filthy stalls their milk is the more likely to undergo speedy putrefaction.

MEDICAL ATTENDANCE ORGANISATION COMMITTEE.

THE fortnightly meetings of this committee continue, and the reports sent us show that the committee has a good grasp of the principal questions involved in any settlement of this complicated question. Sir Spencer Wells has presided at every meeting but the last, and shown as much interest in the matter as if his future prospects were bound up with the movement. The committee have decided on a wage limit, and at the following rates of charge: single persons, male or female, are to pay 6*d.* a month; man and wife without children, 1*s.* per month; man and wife and one child, 1*s.* per month; other children, 3*d.* per month each, not charging for more than four children in one family, making the maximum rate 1*s.* 10*d.* per month. It is clear, as the committee perceives, that the rates must be such as to secure reasonable payment for the medical men. The charges for children are important, for attendance on children will be a large part of the work of such a scheme. At the next meeting the question to be considered will be entrance fees, midwifery, and special rates for sick persons joining.

JEQUIRITY.

MM. HECKEL and SCHLAGDENHAUFFEN arrive at the following conclusions as to the nature of true and false jequirity (a full account of their researches is published in *Der Fortschritt*, Nos. 3 and 4):—That false jequirity (Adenanthera pavonina) does not contain the phlogogenic principle; that the latter exists neither in the peeled seed, nor in the alkaloid, nor in the glucoside; that the testa contains a yellow colouring matter, soluble in water, but which can only be discovered after maceration of the previously bruised seeds; that true jequirity contains—besides the jequiritine discovered by Bruylants and Vennemann—a neutral principle, abrine, distinct from gallic acid and the

Digitized by Google

two colouring matters; that the chemical composition of the true and the false is completely dissimilar, although the two seeds are closely allied botanically; that the bacillary elements furnished by the maceration of either seed are absolutely identical; that the true jequirity only possesses the power of inducing inflammation, which must be dependent on the chemical composition; that the seed of false jequirity, being clearly distinguishable both by its external configuration and internal structure, ought not to be substituted for the true jequirity.

THE TYNE PORT.

IN the Tyne port nine infectious cases were received into the floating hospital during 1886, and the regulations as to the compulsory notification by ship-masters of all such cases is working well. No less than 596 vessels were boarded in the port on account of coming from cholera-infected or suspected ports, and 119 vessels reached the Tyne direct from Bilbao. In the current work of the port we find that 14,080 inspections of vessels were made, and in 651 cases notices as to nuisances were served, structural alterations being required in 61 cases. This work is effecting great good, and Mr. Henry Armstrong is already able to report that great improvement is noticeable both in the cleanliness and in the crew spaces of the vessels examined. With the increasing work of port administration, the old floating hospital was found to be insufficient, and it is satisfactory to report that an excellent and typical floating establishment, consisting of three separate ward pavilions built on cylindrical iron pontoons, was launched during the year. The administrative arrangements are separate, and these are now undergoing improvement. The Tyne port authority has long been carrying out excellent work, and this year's record affords another proof of the maintained interest in the healthiness of shipping and seamen.

TEMPERANCE IN THE NAVY.

AT a meeting presided over by Archdeacon Farrar, a satisfactory account of the progress of temperance in the Navy, especially under the auspices of Miss Weston, was given. Miss Weston said there were over 10,000 abstainers in the Navy, including 200 officers, and that half the boys in the training service were teetotalers. Mr. Caine said that, when Civil Lord of the Admiralty, he was helped and complimented by the admirals for his attempts to favour substitutes for sailors' grog. It must be admitted that poor Jack needs all the help he can from high officials and kindly people like Miss Weston. Too often his case is, as the poet has it,

> "Saved from the sea,
> And shipwrecked on the land."

THE BRADFORD FEVER HOSPITAL.

THE Bradford Corporation have at last decided to purchase for a sum of £10,000 the Bradford Fever Hospital, which it originally cost £30,000 to erect. One point which seems to have led to the final decision was the necessity of providing a small-pox hospital, and it will certainly be easier for the Corporation to isolate that disease on a site which has often received small-pox cases before than to establish a new small-pox hospital elsewhere. The Bradford Fever Hospital has, in the hands of its Board of Management, done admirable work up to the present time, and those who have been responsible for its working deserve a tribute of praise for their past labours in preventing the spread of infection in and about Bradford. Last year alone no less than 726 cases were admitted, 625 of these being cases of scarlatina. The death-rate for the year was 5·37 per cent., or the lowest on record. The hospital premises lie on the outskirts of the borough, and occupy an area of nearly eight acres in extent.

PREGNANCY IN AN IMPERFECTLY CANALISED UTERINE CORNU.

DR. NETZEL mentions, in a Scandinavian journal, a rare case of pregnancy occurring in the imperfectly canalised half of a bicornate uterus. The movements of the child had ceased in the thirty-third week of conception, and from that time the woman became thin and felt ill. Five months later Dr. Netzel was called in; the diagnosis was uncertain. He could not find anything corresponding to an extra-uterine pregnancy, and it was clearly not a normal intra-uterine one. He performed laparotomy, and thus discovered that conception had taken place in the right half of a bicornate uterus. An elastic ligature was applied round the base of the tumour. The uterus was opened and a macerated fœtus extracted. The half of the uterus was amputated with the tube and ovary. All went well until a month after the operation, when an abscess formed in the cicatrix of the abdominal wound, which was followed by a fistula. A quantity of silk and elastic ligatures came away a month later, and the woman ultimately recovered completely. Dr. Netzel thinks the rarity of such cases causes them to be confounded with extra-uterine pregnancies, and with the "missed labours" of English obstetricians. He is of opinion that a more frequent resort to laparotomy would be of much service in throwing light on the subject. He mentions eight more or less doubtful cases as occurring in literature, including one reported by Dr. Keith of Edinburgh.

QUEEN'S COLLEGE (BIRMINGHAM) MEDICAL SOCIETY.

THIS Society celebrated its hundredth general meeting on Wednesday, Feb. 23rd. Sir Walter Foster is almost ubiquitous, for the records of the Medical Council show that on that day he was present at its discussions. Nevertheless, he was the orator of the hundredth meeting at Birmingham, and spoke well on the advantages of the Society as tending to cause improvements in their way of thinking, in their power of speaking, and in their power of action. He referred with pride to the eloquence associated with Birmingham, and made allusion, fit and graceful, to this quality in two much-respected, and, alas, now much-missed, Birmingham men, Dr. Heslop and Mr. Sampson Gamgee. He described to the Society the position of the medical bodies in England and Ireland, and the efforts of the Medical Council towards inducing the Colleges to combine with the Apothecaries in Ireland and England, and so realise to some extent the one-portal for which the profession has long wished.

E. W. ALABONE.

WE observed with much regret in the columns of the *Illustrated London News* of last week an announcement respecting Mr. Edwin William Alabone, whose name was removed from the *Medical Register* in November, 1886. We are, however, authorised by our respected contemporary to state that the announcement "was inserted inadvertently as an advertisement, and came through an advertisement agent." An intimation to this effect will, we are informed, appear in the *Illustrated London News* of this day.

THE PERILS OF FOOTBALL.

THE great winter game of football continues to manifest its claims upon the services of medical men, and also, alas, of coroners. It is most regrettable that a pastime good and useful in many ways, and popular beyond all cavil, should be apparently incapable of reasonable reform. Yet another death is recorded. An inquest was held at Manchester last week on a young man named Makin, who met with fatal injuries in a football match. Deceased was playing in a Rugby

Digitized by Google

game, when he ran against another player and was accidentally struck in the abdomen. He fell unconscious, and died two days later. The coroner commented on the rough character of the game, and warned players that they ran great risk of being charged with manslaughter. A verdict of accidental death was returned. The coroner is to be commended for his outspoken and very necessary comments, which should be taken to heart and acted upon, not only by individual players, but also by the authorities of the Rugby Union and the Football Association.

THE VOLUNTEER MEDICAL STAFF CORPS.

THE first presentation of prizes in connexion with the London Division of this important corps, which is largely composed of medical students, was held at the St. James's Restaurant on Friday, February 25th. The prizes were given by Lady Crawford. Sir Thomas Crawford, K.C.B., Director-General of the Army Medical Department, General Freemantle, and other distinguished visitors, were present. In the evening Sir Thomas Crawford presided over the dinner given by the officers of the corps, at which several well-known members of the profession were present, the civil element being well represented. After the staff had dined, a visit was paid by them to the non-commissioned officers' mess in another part of the building, and the manner in which they were received was evidence of the excellent feeling which exists in the corps. Much credit is due to Surgeon-Commandant Cantlie and Surgeon Lees Hall, A.M.D., for their excellent arrangements.

TESTIMONIAL TO PROFESSOR AITKEN.

IT is proposed in recognition of the great service rendered by Professor Aitken, F.R.S., to his profession generally, and to the medical officers of the Army, Navy, and Her Majesty's Indian Army, by his writings on medicine and his teaching in the Army Medical School, and in admiration of his high personal character in public and private life, to invite him to sit for his portrait, to be placed at Netley, the scene of his labours, and the home of the school with which his name has been honourably associated from its foundation. An influential committee has been formed to carry out this scheme, and numerous subscriptions, which are limited to one guinea, have already been promised. The honorary secretary and treasurer of the fund is Surgeon-General W. Campbell Maclean, M.D., C.B., 28, Carlton-crescent, Southampton, to whom subscriptions and promises of support may be sent.

INTRA-OCULAR CYSTICERCUS.

DR. VAN DER LAAN, writing in a Lisbon journal, gives an account of an ophthalmic case which puzzled him for some time. A man had been suffering from inflammation in the left eye for about a year. On examination there were found serous irido-choroiditis, almost entire loss of vision, opacity of cornea, and increased intra-ocular tension. Several times paracentesis was performed with some benefit. Iridectomy being refused, mercurials and purgatives were given for twelve months, during which time considerable improvement had taken place, ultimately permitting an ophthalmoscopical examination to be made. The retina was seen to bulge forward in one spot, where it was of a yellowish white, the prominence increasing as time went on. It was observed that its form varied, being oblong and round by turns; the patient also said that he sometimes felt something moving in his eye. He then remembered that, when two years previously he had consulted a country practitioner, he had stated that he could "detect an organism, possibly the ovum of a tænia," a diagnosis which now proved to be correct. Dr. Van der Laan has published descriptions of the only two other cases of intra-ocular cysticerci he has seen in Portugal, which in many points differed from this case. He does not propose to operate until the cysticercus has succeeded in perforating the retina and thrusting its head and neck into the vitreous, when he hopes by means of a sclero-choroidal incision to free the patient from his parasite and to preserve the sight of the eye.

DEGREES FOR LONDON MEDICAL STUDENTS.

ON Friday, Feb. 18th, the London Hospital students held a mass meeting in the Anatomical Theatre to discuss the M.D. scheme for London students. Dr. Langdon Down took the chair, and was supported by Mr. F. Treves, Dr. Francis Warner, Mr. Munro Scott (Warden), and Mr. H. G. Lys. Mr. F. Treves proposed, and Mr. J. Moore seconded, a motion, "That a committee of students be formed to draw up a petition to the two Royal Colleges, praying them to use their best endeavours to obtain the power of granting a degree in Medicine; and that this committee take such other steps as they may think fit to support this petition." Dr. F. Warner spoke in support of the proposition, which was carried *nem. con.* Messrs. J. Moore, F. H. Taylor, Hugh Smith, H. Watts, and J. Rayner were elected on the committee, the latter to act as secretary. The meeting was very enthusiastic throughout.

DEATHS OF EMINENT FOREIGN SCIENTIFIC AND MEDICAL MEN.

THE following deaths are announced:—Dr. Leopold von Pebal, Professor of Chemistry in Gratz, was attacked in the Chemical Institute on Feb. 17th by a discharged servant, and wounded so seriously that, though he managed to drag himself into the caretaker's apartments, he died soon afterwards. Dr. Beschütz, Sanitätsrath of Salzwedel, has died suddenly in his eightieth year, having continued to practise till the last. Dr. T. R. von Hüttern, Director of the Lainzer Lunatic Asylum in Vienna. Dr. Franz Günther, Emeritus Professor of Forensic Medicine in Prague, at the age of seventy-four. Dr. Bonnamy, Professor of Anatomy in Toulouse, joint author with MM. Broca and Beau of a well-known anatomical atlas. Professor Ludwig Bandl, the eminent gynæcologist, who had only recently been appointed to the obstetric chair at Prague, at the age of forty-four.

CALCULUS AS THE CAUSE OF PERITYPHLITIS.

A SWEDISH surgeon, Dr. Sigurd Lovén, has published the notes of a case of perityphlitis, followed by a tumour in the ileo-cæcal region, and abscesses opening over the coccyx through the abdominal walls and rectal walls. Ultimately a calculus was passed through the abdominal wound weighing 79 centigrammes, and measuring 2·5 centim. by 1·3 centim. It was composed of alkaline phosphate of lime. Dr. Lovén believes this had existed for a considerable period, and that its situation had been in the vermiform appendix.

THE REVOLVER.

IT is indeed time that Parliament should recognise the appalling results of the indiscriminate and reckless way in which revolvers are allowed to be sold—and used! On one page of an evening paper this week were recorded two distinct cases of suicide, and also a case of suicide and attempted murder, all by means of the revolver. Cannot the Legislative Assembly find time to restrict the awful facilities of destruction now afforded to the burglar, the suicide, and the murderer? Every revolver should be numbered, licensed, and specially and heavily taxed. Those who really require them in this country for purposes of

Digitized by Google

defence—and they must or should be few—can well afford to pay. Many a life has been sacrificed owing to "the sight of means to do ill deeds," as represented by the fatal revolver.

ST. BARTHOLOMEW'S HOSPITAL.

THE Assistant-Physiciancy at the above hospital, rendered vacant by the resignation of Dr. Wickham Legg, has been filled by the election of Dr. Samuel West, who obtained a very large majority of votes.

BORATED FISH.

WE have received from Mr. T. Christy some samples of "kippers" cured by the boracic acid process, and some Scotch "kippers" that have not been so treated. We have examined the specimens, and they support the truth of our assertions on this subject—viz., that boracic acid is not truly preservative of all the qualities of the fresh herrings. The borated specimens are black down their central parts, but the Scotch specimens are clear and fresh-looking. In the process of cooking the black colour of the borated fish becomes enhanced.

FOREIGN UNIVERSITY INTELLIGENCE.

Breslau.—Drs. Wiener and Lesser have been promoted to extraordinary professorships.

Bucharest.—The Professorship of Histology and Bacteriology has been filled by the appointment of Professor von Babes, of Buda-Pesth.

Erlangen.—Dr. Richard Frommel, of Munich, has been invited to accept the chair of Midwifery.

Halle.—The University is about to build an Institute for Mental Diseases, to accommodate 150 patients.

Innsbruck.—There are here four chairs vacant—viz., those of General Pathology, Medical Jurisprudence, Midwifery, and Ophthalmology.

Prague (German University).—Professor Heubner, of Leipsig, has accepted the invitation to the chair of Therapeutics. Professor Schauta, of Innsbruck, has been appointed to the chair of Midwifery, vacant by the death of Professor Bandl.

AT a meeting of the Committee recently appointed to collect subscriptions in aid of the Dundee Medical School Jubilee scheme, on the 24th ult., it was reported that the Senatus Academicus of St. Andrews University desired to co-operate with the Committee, reserving the claim of St. Andrews to a share of the medical teaching. The two Principals of the University have indicated their willingness to join the Committee, and it is stated that other members of the Senatus will also join. Subscriptions amounting to £19,000 have now been received in furtherance of the scheme.

CORRESPONDENCE has been in progress for some months between the Admiralty and influential committees at Plymouth, Portsmouth, and elsewhere, with reference to the increase of disease among sailors and soldiers. As a result, official information has been received that the Lock Hospitals for the accommodation of voluntary patients will be re-opened from April 1st, and that at Devonport the Admiralty will contribute £35 per bed for each of the beds. Similar grants will be made at Portsmouth and other naval ports.

DR. G. Y. HEATH, President of the Newcastle-on-Tyne College of Medicine, has been elected representative of the College on the Senate of the University of Durham; the Professor of Medicine having been made an official member of the Senate, and an elective member having been continued to the School.

A CASE of myxœdema was exhibited at the Berlin Medical Society by Professor Senator on Feb. 9th. He remarked that this was only the second case observed in Berlin, the other having been reported by Dr. Riess at the end of last year. Together with two cases described by Professor Erb of Heidelberg, this case made the fourth reported in Germany.

M. COURBARIEN, intern of the maternity department of La Charité, Paris, died recently from typhoid fever, at the early age of twenty-eight years. He was a man of much promise, and was highly esteemed, as evidenced by the testimony given by Dr. Budin, in his speech on the occasion of the funeral. (*Le Progrès Médical*, No. 9.)

THE condition of Professor von Arlt, which for a time has been satisfactory, has suddenly changed for the worse, so much so, indeed, that the death of the renowned ophthalmologist is almost daily expected.

WE are glad to learn that the health of Dr. De Chaumont has improved, the more urgent symptoms of his late attack of illness having passed away.

SENOR DON DR. RODOLFO DEL CASTILLO and several other practitioners in Cordova, are forming a local Spanish Society of Hygiene.

ABSTRACT OF REPORT
ON THE
SANITARY CONDITION OF NEW WINDSOR.
BY DR. HUBERT AIRY AND MR. ARNOLD TAYLOR.

THE following is an abstract of the Report on the Sanitary Condition of New Windsor which the Local Government Board have just published. After stating the circumstances which were the occasion for holding the inquiry, the inspectors (Dr. Hubert Airy and Mr. Arnold Taylor) describe the situation of the town and discuss its population, which is estimated to be 12,500, this number including the Household Troops, which at the last census numbered 1047.

Under the heading *dwellings*, account is given of the situation of the houses, the greater part of which are on the alluvial plain that stretches at the foot of the western slopes of Windsor. "Certain rows are built on such low ground that when the river overflows its banks and floods the meadows, their ground-floors are two or three feet under water. One quarter also in the older part of the town suffers from the same cause; this is the lower part of Bier-lane and its side courts." In 1852 "the water was in the houses for seventeen days, during which time the inhabitants had to live in the upper rooms; the last serious flood was about five years ago. ..... Besides the temporary inconvenience, there is the layer of mud which is left behind on floors and furniture as the water subsides, the destruction of wall-paper and plaster, and the saturation of walls and floors, which it takes months to get rid of; and there is the still more permanently injurious condition of damp subsoil affecting these dwellings at all times. ..... There cannot be a doubt that this is an unwholesome state of things; to it is probably due a rather high mortality from phthisis in Windsor." Although the Town Council have no power to require dwellings already built in low-lying situations to be altered in such a way as to raise their ground floor above flood level, this has been voluntarily done in one row by the owner. The newer rows of houses have advantage of greater air space about them and have the requisite facilities for through ventilation.

Old Courts.—"But when we come to examine the older courts and alleys of the town, we find that, though in many cases the houses stand on fairly sound ground, their con-

Digitized by Google

dition in respect of outside air space, back yard space, internal ventilation, closet accommodation, surface formation, and pavement—in some and all of these particulars—is still pitiably bad. We, however, willingly recognise that there is evidence of structural improvements having been made in the older courts and alleys in recent years."

The following are some of the details given:—Bier-lane: 170 yards long, 5 yards wide at the top, widening to 12 yards. On the east side is a butcher's shop, with slaughter-house at back; "might be more cleanly kept. Next is a shoemaker's shop, with narrow back yard, widening from 3 ft. to 8 ft. across, ashpit recently emptied, gully out of repair, w.c. in the dwelling without ventilation, walls damp." Next come five capital houses, with workmen's club room and a brewhouse. On west side are two common lodging-houses; then comes entry to Garden-court, which contains twenty-one cottages, ten of which on left side lie close under high retaining wall; their back yards, or rather closet-wells, are only from 4 ft. to 6 ft. across, and contain each a pan-closet, to be flushed by hand. "Water has to be fetched from a standpipe near the entry to the court. Ashes are deposited at the head of a back lane beyond the entry of the court. Each cottage has three rooms, one above another, cubic space from 700 ft. to 800 ft., from which should be deducted the space occupied by bedding &c.; they have no back windows; the front windows are from 3 ft. to 3 ft. 6 in. square. The cottages in opposite row are similar, but, if anything, their back space is still smaller; this space is half roofed over, and made to serve as pantry, or netted over to keep the cats out." Many of the houses are damp. No serious overcrowding discovered. "Lower down in Bier-lane are some old cottages, partly dilapidated, which, the inspectors understand, are going to be pulled down. On the left side formerly stood Red-lion-row; seven new houses are being built here. "On the right side space is less closely occupied: there is, first, a detached house with central stair and a room on each side, top and bottom; no back window, except at the top of the stair. Next are two cottages under one roof, with small gardens in front. The pan-closet belonging to one of them is in a dark recess in a narrow covered yard off the scullery. The inhabitants are laundresses, who flush their closets with their suds. Next come two six-roomed houses of better class, but with ill-paved yard. A pump by the pathway supplies this court with water." Again returning to Bier-lane, the inspectors noted some fairly decent cottages, and came to a passage leading to Distil-House-row, consisting of eleven cottages on the right hand and two more at the further end facing the entry. "In front of the row is a space of bare earth bounded by a blank wall, against which stands the pump, which serves for the common supply of these thirteen houses. Near by, at the foot of the wall, are cavities in the ground, which receive ashes and house refuse.....Some of the interiors showed neatness and cleanliness and comfort, others the reverse; one, containing five children besides the parents, was found to be very dirty. Each cottage in the row has front kitchen (cubic space about 770 ft.) and scullery (540 cubic feet) at back, with bedrooms above, the back bedroom having a lean-to roof, which much diminishes its cubic space. Front windows 3 ft. by 3 ft. 6 in., back windows 3 ft. by 1 ft.; but the two cottages that look up the yard have only two rooms each, and have no back windows. All but three have slop sinks in the sculleries; there are also gullies in the front yard where slops are poured; this row has no back yards. At the further end, at the edge of the back lane, stand four pan-closets for thirteen houses; pans dirty for want of flush-water; woodwork giving way. The palings, which should part these closets from the back lane, are almost all pulled down."

South-place contains forty-two houses, on either side of an asphalted passage. "Of thirteen houses on the south side, ten have no opening whatever at the back, no scullery, no closet, and no water but a tap at the end of the row. For closet purposes the sixty-five dwellers in the ten houses have to go into an open yard at the back of the opposite houses on the north side." Some of them are four, others two-roomed; their stairs have no ventilation, and no light except in one instance, where there is a front window on the landing. "On the north side, Nos. 1 to 4 have sculleries, opening into back gardens, and back lean-to bedrooms over the sculleries, with back windows 18 in. square. Each of these houses has its own pan-closet. No. 5 also has a closet. Nos. 25 to 28 in like manner have sculleries and back bedrooms. They open into a common yard, with an old pan-closet and a new cistern-closet. Nos. 6 to 24, with a population of fifty-six, are two-roomed houses, without any back openings; the bedroom, reached by a stair against the inside of the back wall, contains about 800 cubic feet; a certain small degree of ventilation could be obtained by the stair if all doors and windows were kept open together, but practically this is not done. Behind these houses are three open, unpaved yards, common to five or six dwellings, each with the entries from the asphalted passage. One of the houses adjoining each entry has the advantage of a larger bedroom extending over the entry. These yards together contain eight old pan-closets without water and five new cistern-closets, thirteen in all, for a population of 121, reckoning those who come over from the south side. They have taps of town water; one of them has an iron dustbin, the others have merely cavities in the ground at the foot of the house wall." There is plenty of open space at the back; ventilation could be easily obtained by putting in a window at the head of each stair. "As for the houses on the south side, we see no way of rendering them tolerably habitable but by demolishing every third house and converting its site into a yard for its neighbours with a proper w.c. to each. The death-rate of South-place is calculated to be about 24 per 1000."

In Charles-place and Charles-street cottages there are houses without through bedroom ventilation. Keppel-row is another insanitary locality of fourteen houses, fronting a 9 ft. high brick wall with an asphalted passage 8 ft. across between, with no rain spouting in front, only partial at rear. The first six dwellings have each only one bedroom, not 7 ft. high, with no back window; each has a back room or scullery measuring 7 ft. by 7½ ft., with a lean-to roof on the ground floor. Instances are given of the conditions to which this sort of accommodation gives rise. The next eight dwellings have each a small back bedroom, some not occupied on account of the damp. At the back are two unpaved yards; each has three closets, which serve for eighteen houses. There are three taps of town water in the yards; an ashpit near the washhouse door the inspectors found duly emptied, but it is said to be often offensive. Keppel-court has no back openings to its back ground-floor rooms, except where the tenants have removed a brick or two, admitting air from an inn yard.

Special reference is made to the neglected and dangerous state of some Crown property in St. Alban's-street, and of certain houses belonging to the Corporation.

Water-supply.—The town water-supply is said to be good, being derived from a well in the chalk. There are still a number of wells in the town, some like those in Red-lion-row and Distil-House-row supplying several houses in common. These waters are analysed by the medical officer of health, and when found impure the wells are closed; in the case of private wells, it has been thought sufficient for the present to warn the tenants of the probable impurity of the water.

Sewerage.—This is described, and the statement is made that ventilation was originally provided for by means of surface gratings, but complaints were made from time to time of the smell from these gratings, and many of them have been closed in consequence. It would seem that the flushing is not sufficient to keep the long and almost level outfall sewer (with a fall of 3 ft. in a mile) free from deposit, which is thus left in the sewer long enough to decompose and cause offensive effluvia from the gratings. The necessity of diverting certain storm-water is pointed out.

House-drains.—There is reason to believe that in many cases the house-drains are ill-laid and unventilated, and ready to convey poisonous gases direct from the sewer to the house through an untrapped sink-pipe or an ill-constructed watercloset. The means at the disposal of the Sanitary Authority for dealing with this difficulty have been not so much by way of prevention as by removal of such of the defective conditions as had demonstrated themselves to be nuisances injurious to health. The code of bye-laws in course of preparation will not avail to prevent bad drainage arrangements and ill-constructed closets except in the case of new and rebuilt houses. It is requisite that public opinion should come to the aid of the Sanitary Authority in this matter.

Closets.—Windsor is decidedly in advance of those towns which have vault-privies; the worst thing in Windsor is a pan-closet, constructed to be flushed by hand, which has become coated with dirt or temporarily choked for want of

Digitized by Google

water. Now and then it was found the pan was broken by some rough usage, and it was evident there was untrapped air communication with the sewer. While not to be compared to the foul privies that still disgrace so many towns, yet these Windsor pan-closets ought to be kept in better order, and there ought to be such a system of inspection as should ensure this being done. For the credit of the town, it is to be hoped that this improvement will be generally made. The existing accommodation is in places not sufficient.

Ashes and House Refuse.—There is a weekly collection of house refuse, the inhabitants bringing out their dust in boxes and pails; those who will not take this trouble are requested to give notice at the surveyor's office when they desire the refuse to be removed from their premises. It is carted to a field one mile and a half from the centre of the town, where it is used for filling up hollows in the ground.

Isolation of Infectious Disease.—A hospital for this purpose is urgently needed, and in connexion therewith it is very desirable there should be a suitable disinfecting chamber. The authority offer a fee of 2*s.* 6*d.* for every case of infectious disease notified by a private practitioner to the medical officer of health.

Bye-laws.—The need for their revision has long been recognised, new bye-laws are on the point of receiving the sanction of the Board.

Sanitary Staff.—The medical officer of health is an able and conscientious officer, and the inspectors find in his annual reports evidence of much good work in his district, and sound advice offered to his authority. Evidence is given of the scientific spirit in which he approaches his work. It must be objected, however, that he has under-estimated the importance of such sanitary defects as have been described in connexion with South-place, or else has over-estimated the difficulty of dealing with its defects The inspector of nuisances has done very useful work in organising the present system of refuse-removal, and in bringing about countless improvements; but it is evident that his duties are too multifarious to allow him to give the time that is required for continuous detailed sanitary inspection. The work of nuisance inspector is enough to demand a man's whole time, and the Sanitary Authority ought not to content themselves with less. The inspector of nuisances has also to act as borough surveyor, inspector of common lodging-houses, of weights and measures, of petroleum, and of canal boats. Most, if not all, of the courts and streets might have been dealt with—externally, at least—under the 150th and following sections of the Public Health Act; but, as far as the inspectors could learn, no attempt appears ever to have been made to use these sections, nor is it possible to do so as long as the inspector has so many other duties to discharge in addition to those that properly pertain to the office of borough surveyor. In looking through the Nuisance Report Book, the inspectors could not fail to notice that in the single month of September, 1886, there are as many cases of premises inspected and nuisances reported as in the two years from September, 1884, to August 1886.

Mortality.—The average death-rate is 16·3 per 1000, but this low rate is certainly in part accounted for by the excessive proportion of inhabitants of the ages between ten and thirty, and the low birth-rate. The zymotic death-rate is also low.

Conclusion.—The sanitary condition of Windsor is in most respects no worse, and in some respects is distinctly better, than that of many other old towns with which the inspectors are acquainted. Provided the Town Council have a sufficient staff of officers acting under their orders, the sanitary defects which have been pointed out will in the main be satisfactorily remedied.

Recommendations.—With regard to the sanitary defects in the areas referred to, especially in point of through ventilation and outside air space, the sanitary authority should inquire whether the requisite improvements can be obtained under the powers of the Public Health Act, 1875, and, if not, they should resort to the powers given by the Artisans and Labourers' Dwellings Improvement Acts, 1875 to 1882. In order to secure more constant and thorough nuisance inspection the sanitary authority should appoint a separate inspector of nuisances. They should also make provision for the isolation of infectious disease and for the disinfection of infected articles, and should take into consideration the question of providing a furnace for the destruction of house refuse.

THE PEABODY IMPROVED DWELLINGS TRUST.

THE twenty-second annual report of the trustees of the Peabody Donation Fund is satisfactory, whether viewed from a financial, social, or sanitary point of view. The half-million of money given and bequeathed by Mr. Peabody between the years 1862 and 1873 has by the accumulation of rent and interest very nearly doubled itself, for on Dec. 31st last it amounted to £910,668. That the object of the donor has been faithfully carried out is evident from the fact that by the end of last year the trustees had "provided for the artisan and labouring poor of London" 11,150 rooms, without counting bath-rooms, laundries, and washhouses, and that these rooms were occupied by a population of 20,228 persons; this shows an increase of 12,431 upon the number in residence at the end of 1876, ten years before. The various buildings contained 5014 separate tenements, including 74 of four rooms, 1782 of three rooms, 2350 of two rooms, and 808 of single rooms; the average rent of each tenement being rather more than 4*s.* 9*d.*, and of each room rather less than 2*s.* 2*d.* It is stated that the average weekly earnings of the head of each family in residence at the close of the year was rather less than 23*s.* 10*d.* If this information, which is presumably supplied by the tenants themselves, is trustworthy, it furnishes a complete answer to the charges that have been made from time to time that the Peabody Buildings are not inhabited by the class for which they were intended—namely, the "artisan and labouring poor." The report contains the usual figures bearing upon the vital statistics for last year of the population of more than twenty thousand persons inhabiting those buildings. The birth-rate was equal to 42·4 per 1000, exceeding by 10 the mean rate for the whole of London. This high birth-rate is evidence of the abnormal age constitution of the population, which contains an exceptionally large proportion of young adults, and consequently of children, and necessarily a very small proportion of elderly persons. The death-rate among this population, including, as is stated in the report, the deaths of those residents who were removed to hospitals, was equal to 19·3 per 1000, which is 0·6 below the mean rate for the whole of London. Bearing in mind that this population belongs exclusively to the working classes, and further that its exceptionally large proportion of young children more than counterbalances the effect of its small proportion of elderly persons, this death-rate may be taken to afford evidence of the sanitary condition of the residential population of these buildings. It should at the same time be remembered that to the reported death-rate of this population should undoubtedly be added a proportion of the deaths recorded in workhouses, to which institutions certain numbers of these classes when out of health or work inevitably drift. It may be stated that nearly 12 per cent. of the deaths registered in the whole of London last year were recorded in workhouses and their infirmaries. It seems certain that such a working-class population as that residing in the Peabody Buildings must actually contribute a still larger proportion of its deaths to the number that occur in workhouse establishments. This disturbing element of the Peabody mortality statistics does not, however, affect the rate of infant mortality, and it is especially satisfactory to learn that in this working class population housed in improved dwellings the rate of infant mortality in 1886 did not record 149 per 1000 registered births against 958, the mean rate in the whole of London.

THE MOXON MEMORIAL.

AT a meeting of the friends of the late Dr. Moxon, held at the Royal College of Physicians on Feb. 1st, Sir William Jenner, Bart., in the chair, the following resolution was proposed by Dr. Wilks and seconded by Sir James Paget, "That in the opinion of this meeting it is desirable to express by public memorial the widespread appreciation that exists of the high character and remarkable personal qualities of the late Dr. Moxon, and especially of the services he rendered in advancing medical science and in otherwise promoting the highest interests of the profession." It was proposed by Dr. Pavy and seconded by Sir Dyce Duck-

worth: "That subscriptions be invited, and that a sub-committee be appointed to decide upon the most suitable form of memorial." These resolutions were unanimously carried.

At a meeting of the subcommittee, held at the Royal College of Physicians on Feb. 8th, the following resolution was proposed by Sir Joseph Lister, seconded by Sir Andrew Clark, and unanimously carried: "That the fund raised by subscription be devoted to the foundation of a scholarship or medal to be awarded by the Royal College of Physicians, and to the erection of a memorial of the late Dr. Moxon at Guy's Hospital."

WILLS OF MEDICAL MEN.

THE will of Mr. Samuel Harrison Evans, M.R.C.S., formerly of Derby, afterwards of Normanton, but late of Landour, Weston-super-Mare, who died on Oct. 30th at Southsea, has been proved at the Wells District Registry by the Rev. John David Evans and Mr. Thomas David Fabian Evans, the nephews, the executors, the value of the personal estate amounting to over £22,000. The testator bequeaths £200 each to the Church Pastoral Aid Society, the Church Missionary Society, the British and Foreign Bible Society, and the Society for Promoting Christianity among the Jews; £50 to the Derbyshire General Infirmary; his household furniture and effects to his wife, Mrs. Chloe Evans; £5000 upon trust for her for life; and numerous and considerable legacies to his own and his late wife's relatives, servants, and others. The ultimate residue of his property he leaves to the person or persons who would have been entitled thereto under the statute for the distribution of intestates' effects if he had died without a will.

The will of James Dickson Steele, M.D., late of 18, Blomfield-road, Maida-vale, who died on April 23rd last, has been proved by Major George de Winton and Mr. Richard Eve, the executors, the value of the personal estate amounting to over £15,000. The testator bequeaths £2000 to the said Major de Winton; £1000 each to his brother Robert Moore Steele, his sisters Mary Stuart Steele and Esther Steele, and to the said Richard Eve; and legacies to friends and others. All his real estate and the residue of his personal estate he gives to his housekeeper, Mrs. Anne Penny, in consideration of her long and faithful services.

The will of Charles Sanders, M.D., late of the Haylands, Chigwell, Essex, who died on Oct. 17th last, has been proved by Mrs. Laura Ann Sanders, the widow and sole executrix, the value of the personal estate exceeding £9000. The testator gives certain plate, the portrait of his grandfather, and also his real estate in the county of Norfolk to his wife for life, and then to his son Charles Edward Bradfield Sanders. The residue of his real and personal estate he leaves to his wife.

The will of Mortimer Balding, M.D., late of St. Albans, Herts, who died on Nov. 23rd last, has been proved by Mr. Albert Balding, the brother, and Mrs. Thomas Gowland Page, the executors, the value of the personal estate amounting to over £3000. The testator bequeaths £50 and his household furniture and effects to his wife, Mrs. Kate Greaves Garling Balding, and he confirms the settlement made on their marriage; he also bequeaths legacies to his sister and to a nephew. The residue of his real and personal estate he leaves upon trust for his wife for life or widowhood, then for all his children in equal shares, and in default of children to his sister Octavia.

The will of John Findlay Lindsay, M.D., late of Great George-square, Liverpool, who died on Oct. 11th last, has been proved at the Liverpool District Registry by Miss Janet Lindsay, the sister and sole executrix. With the exception of two or three bequests of jewellery, the testator leaves all his property, including his interest in certain property in Glasgow, to his daughter Florence Bosquet Lindsay.

The will of Arthur Wynn Williams, M.D., formerly of Montagu-square, but late of Brooklyn, West Drayton, who died on Nov. 15th, has been proved by Mr. Arthur Loughborough and Mr. Freke Dalgleish Williams, the executors. The testator gives certain family pictures to his wife for life, then to his son Trevor Wynn Williams, and then to his son; £50 and all articles of personal, domestic, or household use to his wife; the residue of his real and personal estate upon trust to pay the income to his wife for life, and at her death for all his children in equal shares.

The following legacies have recently been left to hospitals and other medical institutions:—Mr. George Fielder, of Doctors' Commons and West Horsley-place, Leatherhead, Surrey, Proctor, on the death of the survivor of his wife and sister, £500 consols each to Charing-cross Hospital, Middlesex Hospital, Surrey County Hospital, the Seamen's Hospital (late *Dreadnought*), and the London Homœopathic Hospital.—Mr. Thomas Lockerby, of Derwent Villa, Addiscombe, Surrey, £100 to the Royal Infirmary, Glasgow.—Miss Fanny Halsey, of Little Gaddesden, Herts, £100 to the West Herts Infirmary.—Mr. Octavius Edward Coope, J.P., D.L., M.P., of Rochetts, near Brentwood, Essex, and 41, Upper Brook-street, £100 to Middlesex Hospital.—Mrs. Alicia Mary Gaselee, of 2, Cambridge-square, Hyde-park, and Tytherley, Bournemouth, £100 to St. Mary's Hospital.—Miss Emily Barry, of 8, Cleveland-square, Hyde-park, £500 to the Royal Hospital for Incurables, Putney Heath; £300 each to St. Mary's Hospital, Royal Orthopædic Hospital, and the Hospital for Sick Children; £100 to St. Mary's Convalescent Home, Broadstairs, in connexion with the Orphanage of Mercy, Kilburn-park-road; and £100 to the Metropolitan Convalescent Hospital, Walton-on-Thames.—Mrs. Charlotte Broadwood, formerly of Tunbridge Wells, but late of 4, The Mount, St. Leonards-on-Sea, £2500 consols in aid of the Cottage Hospital built by her at Capel, Surrey.—Mr. Stephen Peter Schilizzi, of Park Point, Higher Broughton, Manchester, £400 to the Athens Hospital, Evagelismos, and £300 to the Scio Hospital.—Mrs. Harriett Beckford, of West Hill, Cowes, Isle of Wight, £1500 to the Isle of Wight Infirmary, Ryde; £1000 to the Hospital for Incurables, West Hill, Putney; and £500 to the Metropolitan Convalescent Institution, Walton-on-Thames.—Captain Thomas Ruddiman, of 1, Cavendish-place, Cavendish-square, £100 to the Middlesex Hospital.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5882 births and 3767 deaths were registered during the week ending Feb. 26th. The annual death-rate in these towns, which had been equal to 19·5 and 21·1 per 1000 in the two preceding weeks, further rose last week to 21·3. During the first eight weeks of the current quarter the death-rate in these towns averaged 22·0 per 1000, and was 2·3 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 13·5 in Nottingham, 13·7 in Brighton, 14·4 in Derby, and 16·1 in Sunderland. The rates in the other towns ranged upwards to 27·2 in Newcastle-upon-Tyne, 29·8 in Plymouth, 30·1 in Manchester, and 33·0 in Huddersfield. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 340 and 371 in the preceding two weeks, was last week 372; they included 140 from measles, 94 from whooping-cough, 47 from scarlet fever, 39 from diarrhœa and dysentery, 31 from diphtheria, 21 from "fever" (principally enteric), and not one from small-pox. No death from any of these zymotic diseases was registered last week in Birkenhead, while they caused the highest death-rates in Leicester, Liverpool, Manchester, and Huddersfield. The greatest mortality from measles occurred in Leeds, Manchester, Liverpool, Sunderland, Leicester, and Huddersfield; from whooping-cough in Birmingham and Norwich; and from scarlet fever in Bristol and Blackburn. The 31 deaths from diphtheria in the twenty-eight towns included 14 in London, 4 in Liverpool, 2 in Portsmouth, 2 in Manchester, 2 in Leeds, and 2 in Cardiff. Small-pox caused no death in London and its outer ring, or in any of the twenty-seven other large provincial towns. Only 5 small-pox patients were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had been 364, 373, and 392 in the preceding three weeks, further rose last week to 466, but were 18 below the corrected average. The causes of 114, or 3·0 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bolton, Blackburn, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Salford, Oldham, and Sheffield.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 19·8, 22·0 and 24·3 per 1000 in the preceding three weeks, declined again to 22·5 in the week ending Feb. 26th; this rate exceeded by 1·2 the mean rate during the same period in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 11·0 in Greenock and 16·8 in Dundee, to 24·8 in Glasgow and 33·7 in Aberdeen. The 562 deaths in the eight towns last week showed a decline of 45 from the number returned in the preceding week, and included 33 which were referred to whooping-cough, 30 to measles, 17 to scarlet fever, 11 to diarrhœa, 5 to "fever" (typhus, enteric, or simple), 3 to diphtheria, and not one to small-pox; in all 99 deaths resulted from these principal zymotic diseases, against 76 and 103 in the previous two weeks. These 99 deaths were equal to an annual rate of 4·0 per 1000, which exceeded by 1·9 the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had increased in the preceding four weeks from 19 to 32, further rose last week to 33, of which 17 occurred in Glasgow and 7 in Edinburgh. The 30 deaths from measles also showed a further considerable increase upon the numbers in recent weeks, and include 17 in Aberdeen and 12 in Glasgow. The 17 deaths from scarlet fever, on the other hand, were fewer by 8 than the number in the previous week; 11 were returned in Edinburgh, 3 in Glasgow, and 2 in Dundee. The 11 deaths attributed to diarrhœa, of which 4 occurred in Aberdeen and 3 in Glasgow, scarcely differed from the average number for the season. The 5 deaths from "fever" included 3 in Leith, and showed an increase upon recent weekly numbers. Two of the 3 fatal cases of diphtheria occurred in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 126, 133, and 146 in the preceding three weeks, declined last week to 121, and were 38 below the number returned in the corresponding week of last year. The causes of 78, or nearly 14 per cent., of the deaths registered during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 27·3 and 35·3 in the preceding two weeks, declined again to 30·7 in the week ending Feb. 26th. During the first eight weeks of the current quarter the death-rate in the city averaged 31·4, the mean rate during the same period being but 20·9 in London and 21·7 in Edinburgh. The 208 deaths in Dublin last week showed a decline of 31 from the number in the previous week, and included 8 which were referred to "fever" (typhus, enteric, or simple), 2 to scarlet fever, 2 to whooping-cough, 2 to diarrhœa, and not one either to small-pox, measles, or diphtheria. Thus the deaths from these principal zymotic diseases, which had been 17 and 14 in the preceding two weeks, were again 14 last week; they were equal to an annual rate of 2·1 per 1000, the rates from the same diseases being 1·8 in London and 4·2 in Edinburgh. The deaths referred to "fever," which had been 4 in each of the previous two weeks, rose last week to 8, and exceeded the number returned in any previous week of this year. The fatal cases of scarlet fever, whooping-cough, and diarrhœa were almost identical with those in the previous week. The deaths both of infants and of elderly persons showed a decline from the numbers in the previous week. Six inquest cases and 4 deaths from violence were registered; and 50, or nearly a quarter, of the deaths occurred in public institutions. The causes of 40, or more than 19 per cent., of the deaths registered during the week were not certified.

Correspondence.

"Audi alteram partem."

A NOTE OF WARNING REGARDING THE CONDITION OF ARTICLES OF FOOD SOLD FOR THE USE OF THE DIABETIC.

To the Editors of THE LANCET.

SIRS,—In the interests of patients and for the sake of the credit of the profession, I think attention requires to be drawn to the unsatisfactory character of some of the articles of food that are being sold for the special use of those suffering from diabetes. The principle at the foundation of the preparation of these articles is to furnish a food as free from starchy and saccharine matter as can be practically done, and whilst this object is attained it is desirable, in order to render it acceptable for consumption, that the article produced should present as close an approximation to the food in ordinary use as possible. The chief difficulty, it may be said, lies with a representative of bread. Various substitutes for ordinary bread are manufactured and placed at the command of the diabetic. Some of them are carefully prepared and fairly represent what they should be. Others, on the other hand, although placed before the consumer as of a proper character and charged for upon about the same scale of prices, are but little removed in constitution from the representative product in its ordinary state. Thus, the patient may be deluded into taking that which is positively obstructive to satisfactory progress; and with this, discredit will be thrown upon the profession by the efforts of treatment proving abortive. Gluten flour and gluten bread always contain a certain amount of starch, and it may be considered that the article is in a good state if the amount does not exceed from 25 to 30 (or about this) per cent. Some gluten bread and gluten flour being sold at the present time contain no less than from about 75 to 80 per cent. of starch. The actual figures before me are for a sample of gluten bread 74 and another from the same source 76 per cent. of starch, and for two samples of gluten flour derived from the same establishment 80 and 82 per cent. of starch.[1] These figures, as with those belonging to all my analyses, refer to the article in the dried or water-free state. For

[1] It is only right to state that these samples were not obtained from either of the London vendors of diabetic food.

Digitized by Google

comparison, I may state that the figures yielded for a sample of ordinary wheaten flour were 90 per cent. and ordinary household bread 89 per cent. A biscuit sent to me for examination by the wife of a patient as a gluten biscuit obtained from France contained 84 per cent., and another kind 89 per cent., of starch.

Bran biscuits vary. The figures before me, yielded by the analysis of some that are sold, give about 38 per cent. of carbohydrate expressed as starch; whilst the figures for others amount to from 50 to 60 and upwards of this. Besides starch, bran contains cellulose and lignose. These, under the boiling with sulphuric acid in the process of analysis, are, like the starch, transformed into glucose, and thus comprised in the result obtained. Presumably, however, cellulose and lignose in a great measure, if not entirely, resist the solvent influence of the digestive secretions, and thereby, although carbohydrates, escape passing on to sugar in the system of the diabetic. But the starch of course is in the same position as starch from other sources. The starch removable by boiling water from some ordinary bran, or bran as it came from the mill, amounted to 23 per cent.; with prepared bran sold for the use of the diabetic the amount of starch obtained was practically the same, justifying the conclusion that simply grinding without previous washing constituted the process of preparation adopted.

Macaroni, vermicelli, and semola are also articles announced to be specially prepared for the use of the diabetic. I have never yet come across a sample that could be regarded as suitable. Indeed, they have either resembled the ordinary article in use, or only differed to a slight extent. For instance, taking recent analyses, one sample of macaroni gave 85 per cent. of starch, another 71, and another 78; a sample of vermicelli 70, and a sample of semola 74, per cent. The figures yielded by a sample of ordinary macaroni were 86, and vermicelli 87, per cent.

I am, Sirs, yours obediently,

Grosvenor-street, Feb., 1887. F. W. PAVY.

"LUNACY ACTS AMENDMENT BILL, 1887."

To the Editors of THE LANCET.

SIRS,—In your last issue is a letter from Dr. Rogers drawing attention to an alleged injustice to workhouse medical officers in being prohibited from receiving a fee for certifying lunatics as fit to be removed to asylums. I submit he is entirely wrong in his conclusions and in his interpretation of the proposed statute. The Bill does not prevent the workhouse medical officer from being paid a fee when the patient is removed to an asylum, but only in the case when the lunatic is of such a harmless nature that he can with safety remain in the workhouse. Even under the present law no fee is payable to the medical officer under these circumstances.

Clause 14, which Dr. Rogers quotes, enacts: "No person being a lunatic shall be allowed to remain *in a workhouse* unless the medical officer of the workhouse certifies in writing—(*a*) that such person is a lunatic, with the grounds for the opinion; (*b*) that he is a *proper* person to be detained under care and treatment *in a workhouse* as a lunatic; (*c*) that the accommodation in the workhouse is sufficient for his proper care and treatment.....(2) A certificate under this section shall be in the Form 8.....(3) A certificate under this section shall be sufficient authority for detaining the lunatic therein named against his will in the workhouse *for fourteen days* from its date. (4) No lunatic shall be detained against his will or allowed to remain in a workhouse for *more than fourteen days* from the date of a certificate under this section *without* an order under the hand of a justice of the peace having jurisdiction in the place where the workhouse is situate. (5) The order in the *last preceding* subsection mentioned may be made upon the application of a relieving officer of the union to which the workhouse belongs, supported by a medical certificate in the Form 6 under the hand of a duly qualified medical practitioner, not being an officer of the workhouse, and by the certificate under the hand of the medical officer of the workhouse in the Form 8.....(6) The guardians of the union to which the workhouse belongs shall pay such reasonable remuneration as they think fit to the medical practitioner who, not being an officer of the workhouse, examines a person for the purpose of a certificate *under this section*. The whole of the above-quoted part of the clause simply refers to harmless lunatics detained, and *suitable* for detention, in the workhouse. On the other hand, if not suitable, the 7th subsection goes on to say: "If in the case of any alleged lunatic being in a workhouse, the medical officer thereof shall not sign such certificate—i.e., not feel justified in signing—as in this section mentioned, or if at or before the expiration of fourteen days from the date of the certificate an order is not made under the hand of a justice for the detention of the lunatic *in the workhouse* the medical officer of the workhouse shall forthwith give notice in writing to the relieving officer of the union to which the workhouse belongs, that a pauper *in the workhouse* is deemed to be a lunatic, *and a proper person to be sent to an asylum*, and thereupon the like proceedings shall be taken by the relieving officer and *all other persons* for the purpose of removing the lunatic to an asylum, and within the same time, as by the Lunatic Asylums Act, 1853, provided in the case of a pauper deemed to be a lunatic and a proper person to be sent to an asylum. (8) If the medical officer of a workhouse omits to give such notice to a relieving officer, as by the *last* preceding subsection provided, he shall for each day or part of a day after the first, and before the notice is given, during which the alleged lunatic remains in the workhouse, be liable to a penalty, not exceeding ten pounds." The italics throughout are mine.

In short, the meaning is this. Harmless lunatics may be detained for fourteen days on the certificate of the medical officer of the workhouse alone, provided he considers them suitable cases and the accommodation sufficient; but not longer, except with a magistrates' order given on the certificate of an independent medical practitioner in addition to that of the medical officer of the workhouse. On the other hand, if the medical officer of the workhouse believes that the alleged lunatic is not a proper person, or that the workhouse accommodation is not sufficient, then he must go through the same procedure as is enjoined by the old Act, 16 and 17 Vict., c. 97, and he will be paid according to the provisions of that Act.

I am, Sirs, your obedient servant,

CHARLES GROSS, M.D. Lond., F.R.C.S. Eng.,
Barrister-at-law.

Elm-court, Temple, E.C., Feb. 28th, 1887.

To the Editors of THE LANCET.

SIRS,—The Lunacy Acts Amendment Bill has passed through the third reading of the House of Lords, and will shortly be submitted to the House of Commons. I therefore venture through your journal a few suggestions for the consideration of the medical profession. The treatment of lunatics is considered a specialty. It would benefit the profession and the public at large if the study of lunacy were more generally encouraged by appropriating certain wards in all general hospitals for the treatment of lunatics. According to a report in *The Times* on the second reading of this Bill, the Lord Chancellor stated that "there are 4400 licensed houses in this country." These numbers do not tally with the Fortieth Report of the Commissioners in Lunacy, Appendix N, which only shows ninety-six licensed houses, provincial and metropolitan, including private asylums. One of the objects of this Amendment Bill is to get rid of the private licensed houses, and force all patients into asylums. Putting entirely aside the interest of the medical profession, I submit that it would be detrimental to the community at large. In asylums, the attendants number about one to ten patients. Bad cases are consigned to padded rooms, a practice which too much resembles solitary confinement—a punishment for criminals. From a natural disinclination of charitably disposed persons to visit lunatics, the patients have no society beyond other lunatics like themselves, and attendants, who do not belong to a sufficiently educated class, therefore not companions likely to benefit those of a higher degree. Sufficient precautions are not adopted to prevent self-abuse, though such practice is admitted by the profession to be highly detrimental; and females are much neglected at certain times. In private licensed houses each patient has a separate attendant, and the combined aid of all the establishment, if necessary. Padded rooms are not known; precautions are taken to prevent self-abuse and dirty habits, and the patients have the advantage of the society and the constant supervision of the family. I would therefore recommend that the number of private licensed houses,

Digitized by Google

to receive from three to six patients, should be considerably increased.

It was lately published in *The Times* that there are over 30,000 female lunatic patients in the asylums. It is well known how easily they are excited by the presence of the opposite sex. Why not appoint *lady visitors* for the female wards and private female patients in licensed houses, in place of, as at present, the commissioners and magistrates, all gentlemen, whose visits generally upset such patients. Lady visitors would also better understand the habits and requirements of their own sex. The power which the Commissioners in Lunacy and Lord Chancellor's visitors have for summarily removing patients from one house to another, or from a house to an asylum, without a thorough investigation of the case, and against the will of the friends and relatives, should be abolished. The practice is much too arbitrary for a free country in the present century.

I am, Sirs, your obedient servant,

Surbiton, March 1st, 1887. R. COLLUM, M.D.

MEDICAL ASPECT OF THE EARTHQUAKE AT CANNES.

To the Editors of THE LANCET.

SIRS,—At a few minutes to 6 A.M. on the 23rd of February I was startled in my sleep by a marked oscillatory movement having a S.E. to N.W. direction; a noise, faintly comparable to a couple of trains passing under my house, and the tremor with which my little villa was seized, told my half-awakened senses that an earthquake had most unexpectedly visited this peaceful land. I got downstairs with some difficulty, the staircase rocking so much as to bring to my mind the rolling of a vessel at sea, and I had reached the garden before the vibrations had ceased. The first shock lasted forty seconds; it was followed by two more, less intense and of shorter duration. The following night three somewhat similar vibrations took place, the last one only, which occurred at about twenty minutes past five, being of any intensity and duration. Since then there have been a few mild movements, but so slight that they have scarcely been felt by all. Fortunately for Cannes, these earthquakes have done no material damage; apart from a few superficial cracks in the ceilings here and there, a looking-glass or two broken, and a few clocks which have stopped, we have nothing to lament; no one was injured, and not a single building has been damaged. I was, I must say, somewhat surprised at this result, as the shock on the morning of the 23rd was certainly a severe one, and much injury was caused by it in the neighbouring towns of Nice and Mentone. Cannes has come out unscathed from this ordeal, owing mainly to the hotels, villas, &c., being well built, solid constructions, able, as they have proved themselves, to resist even a severe shaking; moreover, with but few exceptions, the foundations of the buildings at Cannes rest on rock, whilst at Nice and Mentone many have been erected on alluvial soil or on reclaimed land; hence, probably, the reason why the earthquake did us so little, if any, harm.

So much for the physical side of the question. As for the moral one, it was simply disastrous. A regular panic seized upon a very large number of the visitors, and at several of the hotels, for forty-eight hours at least, scenes of the most terrible dismay, especially during the night, occurred—not so much among the sick and invalids, many of whom seemed to have learned patience and resignation from physical suffering, and did not give way to the morbid condition which prevailed extensively among their more healthy and stronger companions. Many cases which I was called upon to see were, after the second night, in such a state of nervous depression or excitation, so dulled or so irritable, so unable to think but of the terrible earthquake, not of the one they had felt, but of something more fearful still to come, unable to sleep, to eat, in fact mentally and physically so ill, that no remedy, no persuasion proved of any avail, and they were advised to leave the place at once if they wished to avoid some more tangible disease. Next to these terror-stricken individuals, in some cases the earthquake proved the occasional cause of sickness; a gentleman, just recovering from an attack of gout, rushed from his warm room into the cold outside, and contracted a severe attack of bronchitis; a lady, convalescent from articular rheumatism, from exposure suffered a sharp relapse; and neuralgia, colds, sleeplessness, &c., have been very common among the delicate people who resort to this winter station, in order to escape the frosts and fogs of England and of Northern Europe.

But, as I write, everything has returned to its normal state; the earthquake, although still the topic of the day, is no longer dreaded by the still large number of remaining visitors and residents of the place; a bright sun, a balmy atmosphere, a blue sky, a calm sea, one and all now reward those—and they are by far the majority—who did not give way to unreasonable fears. The total absence of any damage to property or of injury to individuals justifies our belief that this lovely spot is indeed charmed. When sickness hovered around us, as it did a year ago, Cannes escaped. She has done so again, and, with neighbouring cities almost in ruins, at the best severely shaken, Cannes still offers a safe retreat to those who wish to avoid the bleak March winds of the north.

I am, Sirs, yours faithfully,

H. BLANC, M.D., F.R.C.P.,

Cannes, Feb. 28th, 1887. Physician at Cannes.

TRANSPORT AND TREATMENT OF INFECTIOUS PATIENTS IN THE METROPOLIS.

To the Editors of THE LANCET.

SIRS,—A letter from Sir Vincent Kennett-Barrington in *The Times* of Jan. 21st, under the above title, hardly met with the support it deserved either there or in the medical press. Coming from a member of the Metropolitan Asylums Board, it seemed to me an invitation to the public in general to apply for aid to that body in case of need. Acting on this view, I had an opportunity last week of advising direct application to Norfolk House for the removal of a servant ill with scarlet fever from a house of business in a fashionable part of the parish of St. George, Hanover-square. A telegraphic request for ambulance and hospital accommodation was sent off at 4 o'clock P.M., and a certificate by messenger followed; by 6 o'clock the ambulance with a nurse arrived, and the patient was removed, with no further delay than was needed to procure another certificate from our dispensary resident medical officer, Dr. Percy Rendall. Another time the certificate, very properly required by the nurse, could be left in readiness with the patient. Very little time was lost in this case, as doctor and patient were only separated by the length of one street. The occurrence was notified to the medical officer of health, Dr. Corfield, and in a very short time the room the patient had occupied was sulphured, the bedding being taken away to be stoved and thoroughly disinfected, all without cost to the household concerned.

I wish to contrast with this what happened a few days before near the dispensary, but in an opposite direction. A young girl, living at home with her parents, was engaged to assist by day in a large house near where a servant was laid up, as was said, with cold and sore-throat; at the end of a week the servant reappeared among the others for a day or two until she left for the country as convalescent, then this girl suddenly sickened, and was seen by me on the second or third day, in consultation with Dr. Rendall, to confirm his diagnosis of scarlet fever.

In the one case, a source of infection is not only at once removed from among us, but its course in any other direction prevented; in the other, we trust that the vigilance and tact of our sanitary authorities may eventually, after much care and trouble, succeed in averting further mischief, as far as our district is concerned. But what as to the neighbourhood where the convalescent goes, without any precaution taken, or even a word of warning given? This, however uncertain, is indicative of one way in which country epidemics follow any extension of scarlet fever in London. Want of encouragement delays the Asylums Board in providing for us the accommodation of a convalescent home at Winchmore Hill, in addition to that of perfectly appointed ambulances. *The Times*, in its faint support of the letter above referred to, commends the Board ambulance to anyone "who is able to pay for these conveniences." Now, it is precisely to those who can pay but little, or who cannot pay at all, that they are to be commended. The charge is small; if the expense is not recovered at once, it is saved in the long run, or else all will feel a little as ratepayers, what we know too well as doctors, that "good is often done at a loss."

I am, Sirs, your obedient servant,

Orchard-st., W., Feb. 28th, 1887. WILLIAM SQUIRE, M.D.

THE PRESENCE OF BLOOD IN THE PERITONEUM.

To the Editors of THE LANCET.

SIRS,—My sole object in replying to Mr. Lawson Tait's first letter was to remove a misapprehension under which he seemed to labour as to the aim and object of my experiments, and as to the conclusions which I had deduced from them. It was neither my wish nor my intention to enter upon any discussion with him on the subject of peritoneal surgery. I am therefore somewhat at a loss to conceive with what object Mr. Lawson Tait has again recurred to the subject in your issue of Feb 19th. If it was to expose my ignorance of the surgery and pathology of the human peritoneum, his letter must be regarded as somewhat premature, as I have not as yet expressed any views on either subject, and the extent of my knowledge must therefore be quite unknown to him.

A simple statement that the *function* of the heart in man and in the dog is probably the same does not of necessity imply absolute ignorance on one's part of the pathology of that organ in the case of man; and yet it is on precisely similar grounds that Mr. Lawson Tait bases his charges of ignorance against me in regard to the surgery and pathology of the human peritoneum. If, on the other hand, his letter was intended as a criticism of my paper on "Intraperitoneal Transfusion," now in course of publication, I can only conclude that Mr. Lawson Tait has not even done me the honour of reading the paper which he now proceeds to criticise so adversely. If he has done so, then I must venture to protest, both on my own behalf and in the interests of all fair discussion, against the misrepresentation to which he has subjected the nature of my experiments—a misrepresentation whose completeness can only be fully appreciated by those already acquainted with the subject of transfusion. For, so far from having injected "blood of various kinds and from various sources, foreign and domestic," into the peritoneal cavity, I have expressly stated in my paper that blood of only one kind, and from only one source, was used—viz, that obtained from an animal of the same species as the one operated upon, the behaviour of which, as is well known, is in all respects similar to that of the animal's own blood; and, so far from "dogs and guinea-pigs" having been employed for my purpose, no mention is even made of guinea-pigs throughout the whole course of my paper, and all my experiments, with some two exceptions, were performed on rabbits.

I must confess my inability to see what useful object it can possibly serve to continue a correspondence apparently made up for the most part of explanations on the one side, and personal charges of ignorance and misrepresentation of facts on the other. I trust, therefore, I may be excused if I decline to take any further part in it.

I am, Sirs, your obedient servant,

Edinburgh, Feb. 23rd, 1887. WILLIAM HUNTER.

*** This correspondence must now cease.—ED. L.

CANCER OF THE BODY OF THE UTERUS.

To the Editors of THE LANCET.

SIRS,—I shall be glad to be allowed to make a few friendly comments on Dr. John Williams' interesting Harveian Lecture on Cancer of the Uterus, reported in your issue of Feb. 12th.

Of cancer of the body of the uterus Dr. Williams says: "This is a form of cancer which is much less common than that of the cervix, and, indeed, it was at one time thought that cancer never attacked this part of the organ primarily. *It is certain that the disease occurs much more frequently than is generally supposed.*" (The italics are my own.) We have at the Middlesex Hospital unusual opportunities for the study of the pathological anatomy of cancer of the uterus, as there are on an average more than twenty necropsies made annually on the subjects of this disease. I have been in charge of the pathological department for the last six years, and have paid especial attention to the incidence of cancer on the various portions of the uterus. My experience leads me to the conclusion that primary cancer of the body of the uterus must be an extremely rare affection, as I have not met with a single example of it in more than 120 cases. My colleague, Dr. Sidney Coupland, who preceded me in office, and had an almost equally long experience, tells me that he can only recall one undoubted case of primary cancer of the body of the uterus.

I have met with several cases of malignant disease infiltrating the fundus uteri, but in all it originated in some neighbouring organ or growth, and affected the uterus secondarily. In three such cases the site of the primary growth was a fibro-myoma of the uterus, and in one of these the new growth was a myxo-sarcoma. Dr. Williams describes three out of twelve cases which he has met with, which were believed to be examples of malignant disease of the body of the uterus; in the other nine no microscopical examination of the growth was made. I confess that these cases do not appear to me to be beyond doubt. With regard to Case 22, that of a patient who died in the Middlesex Hospital under the care of Mr. Henry Morris, and on whom I made a post-mortem examination, my recollection (and description in the Pathological Report of the hospital) does not quite agree with the account given by Dr. Williams, as I believe the disease originated in the fibroid tumour and spread thence to the body of the uterus.

I have met with a case very similar to the one described as Case 20, in which there was a communication between the uterus and intestine sufficiently large to admit the thumb. In that case it seemed clear that the disease had spread from the intestine to the uterus, and not *vice versâ*. May it have been so in Dr. Williams' case? Whilst, then, I think that they are wrong who hold that cancer never affects the body of the uterus, yet I believe that view to be nearer to the truth than that "it occurs there much more frequently than is generally supposed."

I am, Sirs, yours faithfully,

Clarges-street, Feb. 15th, 1887. J. KINGSTON FOWLER, M.D.

THE CHILDREN'S HOSPITAL, MANCHESTER.

To the Editors of THE LANCET.

SIRS,—Your Manchester correspondent, in a letter published in your issue of Feb. 26th, refers to some allegations which have been made in reference to the reception of infectious cases into the fever ward of the Children's Hospital in this city, it being insinuated that outbreaks of fever frequently occur in the general wards; and, moreover, that children admitted for one infectious disease contract another during their stay. He further says that this has not been denied. As these statements as they stand are hardly fair to the authorities of the Children's Hospital, may I ask you for space for a few lines in order to put the facts before your readers? The allegations to which your correspondent refers appeared in some letter to the public press, written in anything but a friendly spirit towards the hospital by a critic who had not the courage to sign his name. It can hardly be surprising if under these circumstances the hospital authorities declined to discuss the subject with him in the public press. But I must confess that I expected better things of your correspondent, who, if he had consulted the yearly volume of abstracts of medical and surgical cases, &c., published annually by the hospital, for the last five years, which gives all details of the cases, post-mortems, *infectious disease arising in the hospital*, &c., he would have seen many of the allegations referred to had no foundation in fact, at any rate at the present time. We have undoubtedly a fever ward, which is used solely for the admission of scarlet fever cases, no other cases of infectious disease having been admitted to the ward for at least five years, though during this period there have been several outbreaks of measles and chicken-pox, which have been due to the admission of cases admitted with scarlet fever who were incubating measles or chicken-pox at the time of their admission. I need hardly say that no amount of care on the part of the medical officers can obviate this. With regard to the general wards we have had cases of scarlet fever arising from time to time in them, but the number of these, taking the five years 1881-5 (*vide* abstracts), amounts to less than 1 per cent. of the admissions to the general wards during this period, and in many of these cases the infection was clearly traced to cases admitted incubating scarlet fever; while in the others no definite source of infection could be ascertained. I would ask, Can other children's hospitals where no scarlet fever is admitted show a better record? Or can fever hospitals where scarlet fever, erysipelas, typhus, small-pox, &c., are received show a better case?

Digitized by Google

Your correspondent very properly asks "that the serious attention of the management should be directed," &c., to this important question. I am happy to be able to assure him that for many years past the most serious attention of both the medical officers and board of governors of the hospital has been given to this question, that all cases of infectious disease arising in the general wards have been reported to the medical board, and by them to the general board, with the object of tracing the source of all such cases of infection, and of adopting the most stringent means to prevent the introduction of such disease from without or its transference from within.

I have no reason whatever to complain of the tone of your correspondent's letter as regards this question, but surely he can hardly expect the authorities of the Children's Hospital to waste their time over anonymous critics in the Manchester papers who take no pains to make themselves acquainted with the facts of the case.

I am, Sirs, yours truly,

Manchester, March 1st, 1887. HENRY ASHBY.

"GENERAL HOSPITALS AND PARISH INFIRMARIES."

To the Editors of THE LANCET.

SIRS,—I was pleased to see in your issue of Feb. 12th the boldness with which Dr. Goodhart has advocated a closer connexion between general hospitals and parochial infirmaries, as I believe that it is in this direction we must look for a satisfactory and permanent solution of the difficult problems connected with hospital finance and management. Within less than a mile of the house in which I am writing are three large parochial infirmaries, with an aggregate accommodation for not less than 1200 patients, and probably many more; the professional staff is represented by a total of three chief and three assistant resident medical officers. Compare with this the three nearest general hospitals, with an aggregate accommodation for 144, and a total staff of seventeen, of whom five are resident and twelve honorary. In neither case have I included officers whose duties are connected with out-patient work, and to none of the general hospitals mentioned is a school attached. It is obvious, therefore, that in the case of the infirmaries there must be an immense waste of clinical and pathological material. Even admitting the chronic nature of the majority of the cases treated in the infirmaries, I believe that Dr. Goodhart will agree that many valuable lessons are to be learnt from the study of even these, while there can be no doubt that many cases whose ending it would be of much interest to note, after going the round of the general hospitals, sink into oblivion within the walls of one or other parish infirmary. Curiously enough, an instance of this has just come under my own observation in the case of a man to whom I was called some few days back; he was suffering from some obscure cerebral mischief, and I urgently advised his friends to take him to the hospital, of which he was an inmate some two years ago. He was taken, instead, to the parish infirmary, and I have just been informed is now *in articulo mortis*.

I trust that the ventilation of this subject in your columns may lead to the promulgation of some definite scheme for bringing into touch the parochial infirmaries, the general hospitals, and the medical schools throughout the metropolis.

I am, Sirs, yours obediently,

Feb. 1887. J. FREDK. W. SILK.

BIRMINGHAM.

(*From our own Correspondent.*)

PROPOSED MIDLAND UNIVERSITY.

A PAPER read by the Rev. Dr. Crosskey on this subject at a recent meeting of the Philosophical Society elicited an animated and useful discussion. As the medical element is largely involved in all university teaching in the present day, a claim was put forward by Professor Haycroft, of Mason College, for an extension of facilities for obtaining degrees in a midland centre. It was shown, however, that it would be impracticable and undesirable to establish a midland university for a long time to come, and the arguments against it from a financial point of view were thought to be insuperable in the existing state of difficulty in obtaining the necessary funds. The arrangements for medical teaching at the Birmingham School were pointed out as having been vastly improved, and the association with Mason College established a federation which afforded excellent ground for preparation to any of the examining bodies.

THE JAFFRAY SUBURBAN HOSPITAL.

The inmates of this admirable branch of the general hospital were lately gratified by a visit from Madame Marie Roze, whose kindness and sympathy won golden opinions. With characteristic geniality, she charmed them by singing some well-known songs. She left an impression which will long be remembered, as much by the rare vocal powers of the gifted artiste as by the graceful and kindly manner in which she exhibited her attention to the suffering patients in the various wards she visited on the occasion.

INSTITUTION FOR TRAINING NURSES.

Birmingham possesses an exceptionally well-managed and thriving institution for this purpose. The report shows that there are ninety-four nurses, and that the transactions of the year had been carried out with efficiency and success. The statement of accounts at the annual meeting showed that the total income for the year had been £3225 17*s.*, and the total expenditure £2981 5*s.* 5*d.*, giving a balance of income over expenditure of £244 11*s.* 7*d.* From this sum had to be deducted a transfer to the sinking-fund for the provision for new premises of £100, a condition of things which must be regarded as satisfactory and promising well for the future.

BIRMINGHAM AND MIDLAND COUNTIES SANATORIUM.

Another useful institution, of which the twenty-first annual meeting was held on Feb. 24th, also showed that its place was well maintained in the estimation of the public. In the year 1886 as many as 1016 patients were admitted, the weekly cost of each bed being as low as 6*s.* 4½*d.* The absence of complaints and the gratitude of the patients were marked features in the report, while the financial position was shown to be sound. As a valuable aid to convalescence this institution is well worthy of support.

Birmingham, March 2nd.

LIVERPOOL.

(*From our own Correspondent.*)

THE ASSIZES.

THE winter assizes for the south-west division of Lancashire concluded on the 24th ult., having lasted all but three weeks. Among other cases of medico-legal interest was one from Southport, in which a youth of sixteen was charged with shooting a girl. The bullet entered the girl's heart, and she died soon afterwards. The charge of murder was withdrawn, and the prisoner found guilty of manslaughter. The Oldham poisoning case, which lasted four days, is the third case of the kind which has been tried in this county within the last three years. The case of the women Flannigan and Higgins, which was the first, was a series of wholesale poisonings, the first-named prisoner acknowledging that she had assisted in poisoning eleven persons. The second case, that of the woman Britland, tried in Manchester last summer, showed that three victims had succumbed to poison administered by her. And in this most recent case, since the prisoner was sentenced to death for the murder of her child, a coroner's jury has returned a verdict of wilful murder against her, her mother having died more than a year ago with symptoms of poisoning by atropia. These repeated murders have been much commented on by the daily press, and are calculated to create a very uneasy feeling among the public. It is to be hoped that as time advances it will be found easier to detect the very first symptoms of poisoning, to save the intended victims, and to bring their would-be murderers to justice. This will impress the public more favourably than the conviction of prisoners only after a series of murders.

THE NETHERFIELD-ROAD FEVER HOSPITAL.

Dr. Robertson, visiting physician to the Liverpool parish infirmary, has been selected by the Hospitals Committee for the office of visiting physician to the Hospital for Infectious Diseases recently acquired by the city corporation. Dr. Robertson has had considerable experience in the treatment of these cases, and the selection is a wise one.

Liverpool, March 2nd.

EDINBURGH.

(From our own Correspondent.)

THE SCARLET FEVER EPIDEMIC.

DURING the past week the epidemic has steadily declined in its intensity, and the state of extraordinary pressure at the City Fever Hospital has greatly abated. Although all parts of the city have been affected, the outbreak has been much more severe in the northern and western districts than elsewhere; the epidemic has thus avoided the most crowded districts, and has been worst in the more open and the more opulent quarter. During February 41 deaths have occurred from the disease out of the 597 cases intimated to the city authorities during that time.

THE ARCHITECT AND HEALTH.

Dr. J. A. Russell, F.R.C.S.E., one of the bailies of the city, lectured on this subject last week before the Edinburgh Architectural Association. In describing the status of the architects in the community, he pointed out that theirs was the only profession for which no academic or official form of training was demanded beyond a mere system of apprenticeship. He advocated a system by which they should become thoroughly acquainted with the most recent advances of natural philosophy and with the laws of health in relation to light, heat, ventilation, and drainage. So qualified, he would be ready to see extended to them a monopoly comparable to that enjoyed by Law and Medicine, and with similar powers to suppress irregular practice. Referring to the improved death-rate in children of school age, he had little doubt that it was largely due to the efforts of Board school architects who have provided for the children surroundings better than those of their own homes. In discussing the ventilation of Board schools, he spoke of a mechanical system as that likely to be ultimately adopted, since with the cubic space authorised by the Education Department it was all but impossible to obtain complete ventilation by natural methods. In connexion with this question, Bailie Russell is at present engaged in a research into the atmospheric condition of public buildings of various descriptions throughout the city. The Town Council have authorised a special grant for the purpose, and the experiments are to be carried out in the Public Health Laboratory at the University by Dr. Hunter Stewart and Dr. Cosmo Burton.

SANITARY PROTECTION ASSOCIATION.

The annual meeting of the Association was held last week under the presidency of Professor Sir Douglas Maclagan. The annual report shows that the work of the Association has been largely augmented, and that an increased number of the citizens have availed themselves of its services. The officers of the Association are to furnish plans for buildings arranged to ensure perfect sanitation; to inspect dwelling-houses, and report on their sanitary state; to supply recommendations and estimates for remedial measures, and to carry out alterations. Transactions to the extent of between £2000 and £3000 have been carried on by the Association in the last twelve months. The chairman, in moving the adoption of the report, commented on its favourable nature, and stated that they were not a body striving to obtain dividends, but that their sole object was to carry on an important public sanitary work.

SCIENTIFIC RESEARCH IN EDINBURGH.

The Royal College of Physicians has now perfected the scheme for instituting a research laboratory in Edinburgh. There is a general consensus of opinion that this arrangement will be fraught with great good to the Edinburgh school. The new laboratory, which will be amply fitted with apparatus and all requirements for original work, is to be placed under the care of a well-qualified scientific man and an assistant, and is to be open on an easy arrangement to all would-be workers. This arrangement will bring the opportunity of doing useful work within the reach of many of our younger practitioners who have time to engage in it, but who have till now been debarred from research by the exorbitant tariffs of the University laboratories. The College could not have found a better means of employing usefully a portion of its great wealth.

Edinburgh, March 1st.

DUBLIN.

(From our own Correspondent.)

ROYAL COLLEGE OF SURGEONS.

THE Council have agreed upon a scheme for the granting of a diploma in Public Health, and have submitted the same to the Medical Council for approval. The fee is fixed at seven guineas, and the examination will be a very strict one. The conjoint scheme will be discussed by the Council this week on a motion by Dr. Kidd. Sir Charles Cameron's suggestion for a dual scheme will also be under consideration.

ROYAL MEDICAL BENEVOLENT FUND SOCIETY OF IRELAND.

At a quarterly meeting of the Central Committee held last week, the following resolution was adopted: "That the Central Committee of the Royal Medical Benevolent Fund Society of Ireland have learned with much regret of the lamented deaths of Dr. Purdon of Belfast, late local honorary secretary, and of Dr. John Denham, Dr. H. Kennedy, and Dr. E. G. Brunker, members of the Central Committee; and at this their first meeting since their deaths, desire to express their sense of the loss they have sustained, and their sympathy with the respective families in their bereavement."

CITY OF DUBLIN HOSPITAL.

Last week Mr. H. Gray Croly operated for varicose veins, and removed several inches of the internal saphenous vein in the right thigh and leg. The patient, a female, three weeks since had been operated upon by him in a similar manner on the left lower extremity, and the wounds had quite healed. Mr. Croly uses a drainage-tube, but removes it after a couple of days, as he considers it has a tendency after that to act as a foreign body. He afterwards fired an enlarged knee-joint by the thermo-cautery in the case of a boy with a strumous history. This was followed by an operation for sequestrotomy by Mr. Henry Fitzgibbon for necrosis of the left ulna, occurring as the result of acute periostitis. A couple of weeks previously Mr. Fitzgibbon had removed several inches of the humerus of the right side in this patient, arising from the same cause. A large sequestrum, fully four inches long, was removed. Esmarch's bandage was used, and very much facilitated the operation.

FEVER IN CORK.

The medical officers of the Cork Fever Hospital for the past year state that the increase in the number of admissions, as compared with the previous year, was due to an epidemic of typhoid fever which prevailed in the city during the autumn and winter months. They are glad, however, to be able to note a sensible diminution in the records of the fevers of the present day, as compared with those of years gone by. They hope that there will be a compulsory system of legislation enacted, to be enforced in those places where the sick are lying in their homes of dangerous infectious disease, and that the inmates will not be allowed to walk abroad, sell their merchandise, or associate with their fellow-beings, until such time as they are free from the danger of propagating disease. A good deal has been done, but a great deal more requires to be done before Cork can be called the "Modern Hygeia," which they consider it is justly entitled to by reason of its situation. Better swimming-baths are required for the public; a better system of drainage, and a water-supply so arranged as to effect a simultaneous flushing of all the drains of the city when the tide is out. In order to ensure a better water-supply for the city, the medical staff strongly urge on the corporation, as the urban sanitary authority, the necessity of keeping strict supervision over the river Lee and its tributaries, so as to prevent the possibility of the water-supply being polluted along its course.

MUSCULAR ANOMALY.

I had an opportunity of examining last week, in the dissecting room of the Ledwich School of Medicine, an example of the biceps flexor cruris arising by three heads. The extra head came off below, and outside the insertion of the coracobrachialis, that muscle slightly overlapping it at its insertion. The third head passed down and was inserted into the tendon of the biceps at its posterior aspect. I described a somewhat similar biceps a couple of weeks since, with this difference that the third head was inserted about the middle of the muscle posteriorly. Both these specimens were in females, and on the left side.

DROGHEDA UNION.

Drs. O'Keeffe, Delahoyde, and Callan are proceeding against the guardians of this union for fees due to them under the Labourers Act. The guardians have refused their medical officers a fair remuneration, but last week, without hesitation, gave a cheque for £120 to their solicitor in order to defend the action against the board.

It is intended to present Dr. B. Kennedy, resident surgeon to Mercer's Hospital, with an address and testimonial, as a mark of sympathy with him in the recent prosecution at the police-court, in which he was honourably acquitted.

Dublin, March 1st.

BURMAH.

A CORRESPONDENT at Burmah favours us with the following notes:—

DEATHS OF SURG. E. W. KELSALL AND DR. J. PEDLOW.

THE Official Bulletin of Dec. 7th, 1886, Burmah Field Force, published at Mandalay, says:—"Yemethin, Dec. 6th, 1886. Surgeon Kelsall, Medical Staff, died of cholera this morning." Mr. Kelsall's commission dated March 31st, 1875. He was born on August 9th, 1851. He served in the Afghan war, 1879 to 1880: defence of Candahar. Mentioned in despatches, *London Gazette* of Dec. 3rd, 1880; medal. Also in the Egyptian Expedition of 1882: action at Kassassin; battle of Tel-el-Kebir. Mentioned in despatches; medal, with clasp and bronze star. Mr. Kelsall leaves a wife and family to mourn their loss. He is the second member of the Army Medical Staff who has recently died of cholera in the Burmah Field Force.

Dr. James Pedlow, surgeon, Army Medical Staff, born Oct. 16th, 1851, died of cholera on Oct. 21st, 1886, on the ss. *Rangoon*, while on his way up the Irrawaddy in charge of two sections of a field hospital ordered to Bhamo.

PERILS OF "NON-COMBATANTS" ON THE FIELD.

Surgeon John MacGregor, M.D., of the Bombay Medical Service, has again had a pony killed in action; this time in the Shan Hills (Nov. 1886). In April last, when in medical charge of the expedition against the Ponkan Rachin Saubwá, his pony was shot dead while he was dismounted and dressing a severe gunshot wound of the knee-joint. Dr. MacGregor was for many months senior medical officer of Bhamo, and the first civil surgeon at that place. He was very successful in the operations he performed after the engagement with the Rachins and other marauders.

The following medical officers are in charge of British field hospitals:—No. 4 Field Hospital: Surgeon-Major A. Minto, M.B., A.M.S. No. 5: Surgeon-Major R. de la Cour Corbett, A.M.S. No. 16: Surgeon-Major William Venour, A.M.S. No. 17: Surgeon-Major T. W. Patterson, A.M.S. Surgeon-Major R. Vacy Ash, M.B., has been appointed Assistant to the Principal Medical Officer, Burmah Field Force. Surgeon W. A. Morris, A.M.S., has been appointed to the charge of the Ambulance Corps followers. Surgeon M. O'C. Drury has been appointed to the Charge of the C and D Sections, No. 16 Field Hospital at Katha. Surgeon F. H. M. Burton has been transferred from the Charge of the B Section, No. 5 Field Hospital at Bhamo, to that of the B Section, No. 17 Field Hospital at Bhamo.

Burmah, Jan. 1887.

THE number of in-patients admitted to the Sussex County Hospital during last year was 1247, which added to 147 remaining on the books at the end of 1885, makes the total number treated 1394.

THE SERVICES.

Deputy Surgeon-General R. A. Chapple, recently Principal Medical Officer of the Northern District, has arrived in India for duty in the Bombay Presidency.

On the 26th ult. the remains of Brigade Surgeon John Henry Hunt, Medical Staff, were interred in the Aldershot Military Cemetery, with the full military honours to the rank of a lieutenant-colonel, which relative rank the deceased held.

WAR OFFICE.—Army Medical Staff: Surgeon-Major James Hector, M.B., is granted retired pay, with the honorary rank of Brigade Surgeon.

ARTILLERY VOLUNTEERS. — 3rd Middlesex: Robert S. Fancourt Barnes, M.D., to be Acting Surgeon.

RIFLE VOLUNTEERS.—1st Fifeshire; Lieutenant Charles Edward Douglas, M.D., to be Acting Surgeon.—5th (Isle of Wight, Princess Beatrice's) Volunteer Battalion, the Hampshire Regiment: George Arthur Barr, Gent., to be Acting Surgeon.—5th Lancashire (the Liverpool Rifle Volunteer Brigade): Charles John Macalister, M.B., to be Acting Surgeon.—2nd Oxfordshire: Acting Surgeon G. O. Willis resigns his appointment.

VOLUNTEER MEDICAL STAFF CORPS.—William Collingridge, M.D., Medical Officer of Health for the Port of London, has been gazetted Surgeon to the Volunteer Medical Staff Corps, and appointed Acting Adjutant to the 3rd (Woolwich) division.

MEDICAL NOTES IN PARLIAMENT.

Alleged Insanitary Barracks.

IN the House of Lords, on the 25th ult., in reply to Lord Ormonde, who was supported by Lord Ellenborough, Lord Harris said that he had himself examined the half-yearly reports of the principal medical officer of the Home District made in October and February last, from which it appeared that the drainage at the barracks at Hyde Park was in good sanitary condition. He had also examined the quarterly regimental reports of the regimental officer in charge, and the weekly reports of the same officer for the last seven weeks, and all those reports agreed that the sanitary condition of the drainage in the officers' quarters was good. In June last a very important improvement was carried out in the officers' quarters, when the soil-pipes were put on to the exterior of the wall.

Sandhurst and Woolwich Academies.

On the 28th ult., in reply to the Earl of Strafford, Lord Harris stated that the recommendations of the Board of which the noble lord was chairman were considered so important by the First Lord of the Treasury, the War Office, and by the Secretary of State, that they had endeavoured as largely and rapidly as possible to carry out the changes recommended in their report; but he was sorry to say they had not been able to carry out the changes in such a way as the report suggested. The difficulty of finding sufficient sleeping accommodation for the number of cadets at Woolwich was one of funds. An arrangement was in contemplation for reducing the length of the course, by which the number of cadets at one time would be reduced, thereby increasing the accommodation for those who were there. The room at the Herbert Hospital which the Board suggested should be fitted up for the reception of cases of infectious diseases was, he regretted to say, not available at present, but as soon as possible the matter would be dealt with. With regard to Sandhurst, nearly all the recommendations had been carried out. The recommendations with regard to Woolwich would be carried out by the War Department as rapidly as circumstances permitted.

Lunacy Acts Amendment Bill.

On the 1st inst. the House resumed the consideration in committee of the Lunacy Acts Amendment Bill. In Clause 3—which as it stood when the Bill was first in committee met with strong objection by Lord Selborne and Lord Herschell—the Lord Chancellor introduced an amend-

Digitized by Google

ment, having for its object to simplify and render more speedy magisterial investigation in lunacy cases. The amendment was agreed to, and the Bill passed through committee.

The Pollution of the Upper Thames.

In the House of Commons, on the 24th ult., Mr. Ritchie, in reply to Colonel Dawnay, stated that the Thames Conservancy Board had prepared a series of bye-laws in regard to the pollution of the waters of the Upper Thames by means of sewage from house-boats and steamers with a view to their being submitted to Her Majesty in Council.

The Status of Army Medical Officers.

On the 28th ult., Major Rasch asked the Secretary of State for War what would regulate the status of army medical officers on board ship or for choice of quarters, their relative rank having been abolished.—Mr. Stanhope, in reply, reminded Major Rasch that relative rank was neither actual nor titular rank, but only a classification for precedence, allowances, and widows' pensions. As relative rank served no useful purpose, it had, he stated, been abolished; but the classification which it represented remains and still regulates all such matters as those referred to in the question.

On Thursday, Sir Guyer Hunter asked the Secretary of State for War whether, since relative rank of the medical officers of the army had been abolished, what rank, if any, they now have in the army?—The Secretary for War, in reply, said: A medical officer holds the rank in the army which his commission confers upon him, and under Article 125*a* of the Royal Warrant it is provided that for purposes of precedence, allowances, and widows' pension, medical officers shall rank with combatant officers as there laid down. As a matter of fact, the abolition of the term "relative rank" has not altered the position of medical officers in any respect whatever.

Small-pox Statistics.

In reply to Mr. Barran, Mr. Ritchie said that he had communicated with the Registrar-General, and had been informed that practically there has been no epidemic small-pox worth mentioning in any of the 19 great provincial towns dealt with in the Registrar-General's reports in the last ten years. Only one small-pox death was registered in that period in Leicester itself, but ten more were registered in the Leicester Borough Hospital outside the town. This gives an annual rate of 9 in 1,000,000 living—a rate, however, which, small as it is, was nevertheless higher than the rates at Portsmouth, Norwich, Plymouth, Bristol, and Bradford. The last calculated rate for the registration district of Keighley is for the ten years 1871-80, as given in the last decennial supplement. The annual rate in the district in that decennium was 270 per 1,000,000 living, and higher than in 25 out of the 32 remaining districts in the West Riding; higher also than in either Hull, Bristol, Manchester, Leeds, Oldham, Bradford, or Brighton.

Alleged Wrongful Confinement in a Lunatic Asylum.

In reply to Mr. W. Corbet, who asked the Home Secretary the result of the inquiries promised into the confinement in a lunatic asylum for seven years of a female alleged to be of sound mind, and whose case was recently under the notice of the Board of Guardians of Paddington Union, Mr. Stuart-Wortley said that he had made inquiry and ascertained that the woman referred to in the question was not an inmate of a county asylum, but of the asylum at Darenth belonging to the managers of the Metropolitan Asylums Board. The President of the Local Government Board has accordingly taken up the matter, and is making inquiries as to the case.

Brompton Cemetery.

In reply to Mr. Baggallay, Mr. Plunket stated that Brompton Cemetery contains in all 38 acres and 20 perches. There now remain available for future graves 4 acres and 34 perches. Since the first burial in Brompton Cemetery in 1840 up to Feb. 26th last there have taken place 135,617 burials. The average number of burials in the last three years was in round numbers 5000. The graves are of different depths, and the coffins are placed in the ground subject to restrictions laid down by the Home Office. No limit can, unless by Act of Parliament, be fixed to the number of interments, except that each year there is less space available for the purpose. The Government does derive a profit (which was last year £7070) from the cemetery.

Supplementary Civil Service Estimates.

The House having gone into Committee of Supply, on the supplementary vote of £1800 for the Local Government Board, Colonel Nolan desired further information on the subject of the inspections of local sanitary areas, which had been undertaken by the Local Government Board.—Mr. Ritchie said that in 1885, it having become apparent that there was considerable danger of an outbreak of cholera in this country, it had been proposed by the Local Government Board that inspections which had been made in the previous year at seaports should be extended to inland towns. The Treasury had assented to the employment of five extra inspectors for the purpose of inspecting the sanitary areas throughout the country. The result had been in every way satisfactory, and fraught with advantages of a permanently beneficial character.—Mr. T. Healy complained that in Ireland all such expenses came out of their own pockets.—Mr. Esslemont urged the claims of those Scotch ports which had taken precautions to prevent disease coming in.—After a lengthy discussion, Sir M. Hicks-Beach undertook to inquire into the matter, and if it were found that Irish boards of guardians had incurred extra expenses of the nature covered by this vote, he would urge on the Treasury that a similar vote should be brought forward to recoup the Irish boards of guardians.—Mr. E. Russell asked for a similar assurance in regard to Scotland.—Mr. A. J. Balfour said he would give an undertaking that he would do his best to secure that such expenses be thrown on Imperial funds.—The vote was then agreed to.

Vaccination.

On the 1st inst., in reply to Mr. T. Robinson, Mr. Ritchie said that the Government could not consent to having the subject of vaccination inquired into, either by a Royal Commission or a Committee of the House. With regard to repeated prosecutions for evasion of the Vaccination Act, the views of the Local Government Board were, he remarked, well known. They were set forth in a letter to the Board of Guardians of the Evesham Union, which was presented to Parliament. He could not hold out any hope of legislation with the view of preventing the imposition of cumulative penalties.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At a congregation held on Feb. 24th, the following degrees were conferred:—

BACHELOR OF MEDICINE.—Roger Alan Birdwood, Peterhouse; William Heaton Hamer, Christ's; Edward Lawrence Fox, Cavendish Hostel.

BACHELOR OF SURGERY.—Edward Lawrence Fox, Cavendish Hostel.

COLLEGE OF PHYSICIANS IN IRELAND.—At the February examinations the following obtained licences in Medicine and Midwifery of the College:—

MEDICINE.—James Butler, James Davis Egan, Thomas McCraith Foley, James S. Freeborn, Thomas Morton Frood, William Richard George Hamilton, Vincent Nash.

MIDWIFERY.—James Davis Egan, Vincent Nash, Edward Francis O'Sullivan.

The undernamed have been admitted Members:—

Patrick Thomas Lyster. | Ralph Stone.

BRITISH MEDICAL SERVICE.—The following is a list of candidates who were successful for appointments as Surgeons in the Medical Staff of H.M. Army at the competitive examination in London on Feb. 14th and following days:

	Marks.		Marks.
Smith, H. E. H.	3390	Paterson, J.	2815
Alexander, G. F.	3290	Trask, J. B.	2800
Gore-Graham, W. P. ...	3210	Forbes, N. H.	2785
Woods, E. M.	3195	Freeman, B. C....	2755
Spong, C. S.	3140	Davoren, V. H. W.... ...	2730
Leishman, W. B.	3125	Copeland, R. J....	2720
Rawnsley, G. T....	3060	Blenkinsop, A. P.	2670
Thomson, J.	3040	Borrodaile, A. L.	2640
Reilly, C. W.	2990	Halloran, W.	2640
Crofton, W. J....	2895	Birt, T....	2630
Wright, A....	2880	Peeke, H. S.	2630
Luther, A. J.	2850	Smyth, R. H.	2630
Girvin, J.	2820		

INDIAN MEDICAL SERVICE.—The following is a list of candidates for appointments in this Service who were successful at the competitive examination recently held at

Digitized by Google

Burlington House. Of the 73 candidates who competed for 28 appointments, 70 were reported qualified:—

	Marks.		Marks.
Meyer, C. H. L.	3435	Fisher, L. G.	2995
Elliot, W. H. W.	3340	Buchanan, A.	2970
Childe, L. F.	3320	Manifold, C. C.	2905
Clark, W. R.	3290	Jacob, A. H.	2900
Braide, G. F. W.	3270	Garvie, J.	2890
Murray, J.	3230	Jolliffe, A. R.	2880
Hailey, P. O. W.	3160	Crawford, F. J., M.D.	2770
Marks, E. J.	3150	McEvoy, W. G.	2760
Ker, M. A.	3100	Macleod, H. W. G.	2760
Barry, T. D. C.	3040	Robertson, R.	2750
Gilbert, C. E. L.	3040	Irvine, G. B.	2730
Vost, W.	3040	Moore, T. C.	2730
Herbert, H.	3035	Karney, W. H.	2720
Sunder, O. E.	3000	Simpson, D.	2720

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise on the 24th ult.:—

Carver, Arthur Richard; Wenallt, Carmarthenshire.
Olding, Arnold Ebenezer, Lancaster Villas, Brighton.
Theobalds, Owen Le Marc, East Looe, Cornwall.

A DONATION of £5000 has been received by the committee of the Worcester Infirmary from an anonymous donor.

A CONCERT, which proved highly successful, was given on the 28th ult. by the Children's Orchestra on behalf of the Victoria Hospital for Sick Children.

A PUBLIC MEETING in aid of the funds of the East London Hospital for Children, Shadwell, is to be held in the Egyptian Hall of the Mansion House to-day (Friday), the Lord Mayor presiding.

A DRAMATIC PERFORMANCE, under distinguished patronage, in furtherance of the appeal on behalf of Guy's Hospital, will be given at the Novelty Theatre on the 21st prox.

THE first annual meeting of the members of the Medical Defence Union was held on the 23rd ult., when the report for the past twelve months was read. Mr. Lawson Tait was elected president for the current year.

CITY DISPENSARY.—The Lord Mayor presided at the ninety-eighth annual festival in connexion with this institution on the 24th ult. During the evening subscriptions amounting to nearly £400 were announced by the treasurer.

AT a recent meeting of the Buildings Committee of the Tynemouth Infirmary it was decided to erect a new building at a cost not exceeding £3000. The Duke of Northumberland has signified his intention of giving a site for the new hospital.

SUBURBAN SEWERAGE.—At a special meeting on the 28th ult., the Richmond vestry adopted a petition to the Local Government Board, asking that body to issue a provisional order forming a joint main sewerage board for the parishes of Richmond, Mortlake, Barnes, Kew, and Petersham.

THE annual banquet of the Newcastle Clinical Society took place recently, under the genial presidency of Dr. Oliver, while Mr. W. G. Black acted as a most efficient secretary. The entertainment left nothing to be desired, and will be long remembered by the Society and its numerous guests.

EPIDEMIC OF MEASLES AT STONYHURST COLLEGE.—Stonyhurst College is at present visited by an epidemic of measles of a very virulent type from which several deaths have occurred. The disease was introduced from Germany, and all possible precautions are being taken to confine the disease to its present limits.

ST. PANCRAS AND NORTHERN DISPENSARY.—The annual meeting of the governors of this institution, which was instituted in the year 1810, was held on the 1st inst. The report stated that 2558 cases were treated during the past year, as against 2076 during 1885. The treasurer's account showed there was a balance at the end of the year of £47 18*s.* 2*d.* only. From a letter read during the meeting it appeared that the present is the fiftieth year Her Majesty has bestowed her patronage on the institution.

BEQUEST.—The governors of the East Suffolk and Ipswich Hospital have been informed by the executors under the will of the late Alderman Booth that a legacy of £500, free of duty, is to be paid for the perpetual endowment of the Pembridge Cot in the children's wing of the hospital, with a request that the name be altered to the Booth Cot.

PATIENTS FOR M. PASTEUR.—Dr. Thursfield, medical officer of health for Shrewsbury, left London for Paris on the 2nd inst., accompanied by six patients who are suffering from the bites of a rabid dog. The inhabitants of the neighbourhood have liberally subscribed towards the necessary expenses of placing the sufferers under the treatment of M. Pasteur.

STANLEY HOSPITAL, LIVERPOOL.—At the annual meeting of the supporters of this institution on the 28th ult., it was reported that the total number of out-door patients who had been treated during the past year was 12,475, and of in-patients, 661. From the financial statement it appeared that the receipts amounted to £1730 and the expenditure to £2975, leaving a balance of £2767 now due to the bank.

THE KENSINGTON VESTRY BILL.—This Bill, the object of which is to enable the vestry to acquire land for the purpose of erecting thereon a dust destructor, has been approved by a select committee of the House of Commons. Two conditions have, however, been imposed—viz., first, that the dust should be destroyed immediately and not stored; and second, that a portion of the land to be acquired should be set apart as a public recreation-ground.

DEATH OF AN AGED SPANISH PRACTITIONER.—Don Rosendo Moreno y Valesco, a venerable Spanish practitioner residing in Logroño, who would have completed his hundredth year on Feb. 25th, has just died. Considerable preparations were being made for a public celebration of the day, no misgivings having been expressed as to the probability of Don Moreno living to see it, as up till quite recently he had been in good health and in actual practice.

NEW HOSPITAL FOR MADRID.—*El Siglo Médico* states that the plans of the new Hospital of San Juan de Dios, which is about to be erected by the corporation of Madrid, are most complete. The number of beds provided for is 644. The building is to be in ten pavilions constructed of brick and iron on the Tollet system, and separated from one another. It is expected that the building will not be completed for four years.

THE COLONIAL AND INTERNATIONAL CONGRESS ON INEBRIETY, organised by the council of the Society for the Study and Cure of Inebriety, and unavoidably postponed from 1886, will be held on Wednesday, July 6th, 1887, in the Westminster Town Hall, London, S.W. At the day sittings, after the president's opening address, papers on various phases of inebriety as a disease, and on legislation for inebriates, will be read. The hon. secretary is Mr. C. H. Bishop, 42, Grove-road, Regent's-park, N.W.

PROVIDENT SURGICAL APPLIANCE SOCIETY.—During the past year this Society has helped with instruments 4343 patients, making a total since its establishment of 40,611 who have been relieved. The receipts for the year amounted to £2273, and the expenditure to £2236. This is the first occasion since the formation of the Society, fifteen years ago, that the accounts have showed a balance in hand. The anniversary festival is to be held at Willis's Rooms on the 27th prox.

THE JUBILEE.—In connexion with the Queen's Jubilee in Belfast, it was stated at a meeting of the General Committee of the Belfast Royal Hospital, on the 28th ult., that one of the most pressing necessities in the town was the want of a hospital for consumptive patients, of whom there is a very large number, in consequence of the nature of the employment in which the operatives are engaged in the linen mills and factories. Mr. Foster Green offered to build a new wing to one of the local hospitals, and fit it up for consumptive patients, provided the town supplied a permanent endowment, which would be secured by a contribution of £15,000. Mr. Green will further provide £1500 of the latter amount.—At a meeting at Glasgow on the 28th ult. it was agreed to erect a hospital for the southern district of the city as a memorial of Her Majesty's Jubilee.

Digitized by Google

At a public meeting held at Romford on the 21st ult. it was resolved to erect a cottage hospital in commemoration of the Jubilee. The Duke of Grafton has consented to preside at the festival dinner early in June next on behalf of the extension fund towards the completion of the new wing of the City Orthopædic Hospital, in commemoration of Her Majesty's Jubilee year.—Mr. Tharia Tapan, a well-known British Indian subject at Zanzibar, has announced his intention of celebrating the Queen's Jubilee in that town by giving a suitable building for a general hospital, open to all nationalities, and to endow it with £15,000, subject to the single condition that the building and endowment fund be placed under the protection of the British Government.

LIDDELL PROVIDENT DISPENSARY, JARROW.—At the annual meeting of this dispensary (erected in memory of Canon Liddell, and successfully conducted on the provident system), the medical officer reported that he had paid 4688 visits, and had 7468 consultations at the dispensary, where he had also dispensed 11,195 prescriptions. The financial statement was satisfactory, the institution being self-supporting; but these figures lead one to think that the success of the dispensary must be due to the untiring energy of the medical officer.

NEWCASTLE CHILDREN'S HOSPITAL.—The annual meeting of the Newcastle Children's Hospital has just been held, under the presidency of Sir Wm. G. Armstrong. The number of in-patients treated had been 161, as compared with 156 in 1885, and the number of out-patients had been 2660, as compared with 2483 in 1885, showing that the useful work of the institution had been steadily maintained. The total cost per head per letter for four weeks had been—for in-patients, £2 0*s.* 2*d.*, as compared with £2 12*s.* 11*d.* in 1885.

SCARBOROUGH SEA-BATHING INFIRMARY.—The annual meeting of supporters of this institution was held on the 28th ult., when, in their annual report, the committee congratulated the subscribers on the continued usefulness and success of the institution. During the past year 594 patients have been received, this number exceeding that of any previous year by 32. The expenditure for the year was £1519, showing an increase of £20, and the receipts, including a balance of £92 brought forward from 1885, amounted to £1737.

SHEFFIELD CHILDREN'S HOSPITAL. — The annual meeting of the governors and friends of this institution was held on the 25th ult., when it was reported that the number of individual out-patients during 1886 had been 3626, and that the number of in-patients had increased from 125 in 1885 to 142. The total receipts were £859, and the expenditure was £99 less than the income. It is proposed to erect a new wing in connexion with the hospital, the present accommodation for in-patients being inadequate to the demands made upon the charity.

ST. JOHN AMBULANCE ASSOCIATION.—The Streatham division of the Metropolitan police having undergone a course of instruction in "first aid to the injured," under Deputy Inspector-General M. Coates, R.N., have been examined by Mr. Steet, F.R.C.S., chief medical officer, General Post Office, with the result that the whole of the candidates (twenty-three in number) have been awarded certificates.—Lord Lyttelton presided last Monday at a meeting of the Great Western Railway employés at Paddington, when an address was given by Sir Vincent Barrington, deputy chairman of the above Association.

LONDON SANITARY PROTECTION ASSOCIATION.—The sixth annual meeting of the members of this Association was held on the 26th ult., under the presidency of Lord Chelmsford. The report for the year showed that the number of members was 1144. The number of houses inspected for the first time last year was 398, and the percentage classified as in a bad condition was 59, as against 55 for the previous five years. Suggestions were made for enlarging the operations of the Association by undertaking the inspection of a smaller class of house at a reduced fee, and also the supervision of new building estates on special terms.

THE MEDICO-PSYCHOLOGICAL ASSOCIATION.—The quarterly meeting of this Association was held at Bethlem Hospital on Wednesday, Feb. 23rd. The chair was taken by Dr. Savage. Dr. Baker exhibited a [illegible] of a crib bedstead, with a close top, as recently in use at Utica Asylum. Dr. Savage then introduced for discussion the question, "Whether there is ever sufficient reason for the use of strong clothing and side-arm dressings," which was followed by an interesting debate, in which Drs. Brushfield, Hayes, Newington, S. R. Philipps, Fox, Moody, and Hack Tuke took part. The proceedings concluded with a paper by Dr. Percy Smith, on the "Results of an Epidemic of Typhoid Fever in the Insane."

RABIES.—By an Order in Council, which came into operation on the 1st inst., and is to extend throughout England, Wales, and Scotland, the Privy Council have given special and enlarged powers to local authorities to make regulations for the muzzling of dogs; for the keeping of dogs under control; for the seizure and detention of stray dogs; and for the slaughter of dogs being at large and affected with or suspected of rabies, or having been exposed to the infection thereof. The new order extends not only to dogs, but also to cattle, sheep, and goats, and all other ruminating animals and swine, as well as to horses, asses, and mules.

ROYAL HOSPITAL FOR CHILDREN AND WOMEN.—The annual general court of governors of this institution was held in the hospital, Waterloo-bridge-road, on the 28th ult., the Lord Mayor presiding. The number of in-patients treated during last year was 483, against 479 in 1885; out-patients 7195, against 6015; and suffering children visited at their homes, 417. The annual subscriptions were fully maintained, and the donations showed a slight increase. Still, the total income of the year fell short of that of the previous year by nearly £400, and the total deficit amounted to nearly £800. It was resolved to endeavour to raise a Jubilee fund of £1000 to free the hospital from debt.

Births, Marriages, and Deaths.

BIRTHS.

BOURKE.—On the 23rd ult., at York-crescent, Woolwich, the wife of Surgeon Ulick J. Bourke, Army Medical Staff, of a son.

BURN.—On the 23rd ult., at Richmond, Surrey, the wife of Stacey S. Burn, M.A., M.B.Oxon., of a son.

CLARKE.—On the 22nd ult., at Twickenham House, Middlesex, the wife of Richard Ashmore Clarke, L.R.C.S.I., of a daughter (stillborn).

GODSON.—On the 24th ult., the wife of Clement Godson, M.D., of a daughter.

HASLAM.—On the 24th ult., at Mecklenburgh square, the wife of W. D. Haslam, M.D., M.R.C.S., of a daughter.

HOPE.—On the 28th ult., at Curzon-street, Mayfair, the wife of William Hope, M.D., of a son.

SIMMONS.—On the 20th ult., at Bertram Lodge, Sandown, Isle of Wight, the wife of E. Walpole Simmons, M.B., M.R.C.S., of a daughter.

WHITCOMBE. — On the 26th ult., at Westerham, Kent, the wife of C. H. Whitcombe, L.F.P.S. Glas., L.S.A. (prematurely), of a daughter.

MARRIAGES.

BATTERSBY—BYRNE.—On the 22nd ult., at St. Peter's Church, Dublin, J. Carter Battersby, M.B., Surgeon, Army Medical Staff, to Frances Eliza, eldest daughter of John Alexander Byrne, Esq., Q.C., of Lower Leeson-street, Dublin.

GEORGE—DOWARD.—On the 17th inst., at the Parish Church, Tidenham, Gloucestershire, Hugh George, M.D., to Ellen Maud, third daughter of the late Alfred Doward, of Day House.

LUMPKIN—LEWIS.—On the 26th ult., at St. George's Cathedral, Freetown, Sierra Leone, West Africa, C. Jenkins Lumpkin, M.D., youngest son of the Hon. H. Lumpkin, deceased, to Carrie, only daughter of Wm. Lewis, Esq., sen., and sister of the Hon. Samuel Lewis, of the Middle Temple, Barrister-at-Law.

MOORE—BAKER.—On the 21st ult., at St. James' Church, Hereford, Henry Cecil Moore, M.R.C.S., L.S.A., to Henrietta Elizabeth, widow of Thomas Baker, of St. Albans.

SHADWELL—BOURNE.—On the 26th ult., at St. Stephen's Church, Shepherd's Bush, by the Rev. G. Collett, M.A., assisted by the Rev. A. Matthey, D.D., Harry Winstanley Shadwell, M.R.C.S., L.R.C.P.Lond., of Acton, to Mabel Constance Harriette, youngest daughter of the late Captain G. Lealy Bourne, R.N.

DEATHS.

DRUMMOND.—On the 28th ult., at his residence, Great Cumberland-place, very suddenly, James Drummond, M.D., late of Nice, aged 63.

PRICHARD. — On the 26th ult., at Norton Court, Gloucestershire, William G. Prichard, late Inspector-General of Hospitals, Madras, aged 73.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BARRY, EDWARD JOSEPH, M.D.Ed., M.R.C.S., has been appointed Honorary Medical Officer to the London Skin Hospital, Cranbourne-street, Leicester-square.

BRANSON, JOHN, L.R.C.S., M.R.C.P.Ed., has been appointed Medical Officer for the Rotherham District of the Rotherham Union.

CLARK, DONCAN MCCALLUM, L.F.P.S.Glas., L.R.C.P.Ed., has been appointed Medical Officer for the Auston District of the Worksop Union.

COLE, WILLIAM R. N., M.D., M.Ch. Queen's Univ. Irel., has been appointed Medical Officer for the Seventh District of the Bodmin Union.

COOKE, R. T. E. B., F.R.C.S.Ed., L.R.C.P.Ed., has been re-elected Honorary Medical Officer to the Scarborough Sea-Bathing Infirmary.

GRIFFIN, ALBERT WATSON, M.R.C.S., L.R.C.P.Ed., has been appointed Parochial Medical Officer for the Rotherfield District of the Uckfield Union, vice Matthew Mackintosh, M.R.C.S., L.S.A., deceased.

HACKETT, H. EUGENE, M.R.C.S., L.R.C.P.Lond., has been appointed Medical Officer for the Sixth District of the Chorlton Union.

JONES, JOHN T., M.R.C.S., L.S.A., has been appointed Medical Officer for the Laughton District of the Rotherham Union.

KING, C. GILROY, M.B., C.M.Glas., has been appointed Sanitary Medical Officer for the Parish of Eastwood, Glasgow, vice Walker, resigned.

LLEWELLYN, ERNEST G. T., L.F.P.S.Glas., M.R.C.S., has been appointed Medical Officer for the Sixth District of the South Molton Union.

LYTH, J. B., M.R.C.S., L.R.C.P.Ed., has been elected Honorary Surgeon to the Rotherham Hospital and Dispensary, vice Foote, deceased.

PENNY, FRANCIS, M.R.C.S., L.S.A., has been appointed House-Surgeon to the Doncaster Infirmary, vice Gelston, resigned.

POCOCK, WALTER, M.R.C.S., L.S.A., has been appointed Honorary Medical Officer to the London Skin Hospital, Cranbourne-street, Leicester-square.

POTTER, E. FURNISS, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer to the Victoria Hospital for Sick Children, Hull, vice J. Southter, L.R.C.P.Lond., M.R.C.S., resigned.

SMITH, J. ANDERSON, M.B. Lond., M.R.C.S., has been appointed Resident Clinical Assistant at the Brompton Hospital for Consumption and Diseases of the Chest.

STARTIN, JAMES, M.R.C.S., has been elected Honorary Medical Officer to, and Lecturer at, the London Skin Hospital, Cranbourne-street, Leicester-square.

TAYLOR, JOHN W., M.D., M.R.C.S., has been re-elected Honorary Medical Officer to the Scarborough Sea-Bathing Infirmary.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

ASHTON UNDER-LYNE DISTRICT INFIRMARY.—House-Surgeon. Salary £80, with board and residence.

BOSCOMBE PROVIDENT INFIRMARY, Bournemouth.—Resident Medical Officer. Salary £80 per annum, with board, lodging, &c.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria-park, E.—Pathologist.

DERBYSHIRE GENERAL INFIRMARY, Derby.—House-Surgeon. Salary £100 for the first year, increasing £10 a year up to £150, with apartments, board, and washing.

EAST LONDON HOSPITAL FOR CHILDREN, Shadwell, E.—Resident Clinical Assistant. Board and lodging, but no salary.

GLAMORGANSHIRE AND MONMOUTH INFIRMARY AND DISPENSARY, Cardiff.—Ophthalmic Surgeon.

HASTINGS, ST. LEONARDS, AND EAST SUSSEX HOSPITAL.—House-Surgeon. Salary £70 per annum, with board, lodging, and laundry expenses.

INFIRMARY FOR CONSUMPTION, Margaret-street, Cavendish-square, W.—A Physician in-Ordinary; three Visiting Physicians; and a Surgeon.

MALE LOCK HOSPITAL, Dean-street, Soho.—House-Surgeon. Salary £50 per annum, with board and lodging.

MITCHAM WORKHOUSE, Holborn Union.—Medical Officer. Salary £100 per annum.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury.—Laryngologist.

NORTH-WEST LONDON HOSPITAL, Kentish-town-road.—Assistant Physician.

NOTTINGHAM GENERAL HOSPITAL.—One Resident Surgical, and one Resident Medical, Assistant. Board, lodging, and washing, but no salary.

PARISH OF PUTNEY.—Medical Officer of Health. Salary £75 per annum, rising (subject to the order of the Board of Works for the Wandsworth District) by annual increments of £5 each to a maximum of £110 per annum.

UNIVERSITY OF GLASGOW.—Examiners in Medicine.

WESTERN DISPENSARY, Rochester-row, Westminster.—Resident Medical Officer. Salary 100 guineas per annum, with furnished rooms, coals, gas, and attendance.

Medical Diary for the ensuing Week.

Monday, March 7.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesday, 2.30 P.M.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

ROYAL INSTITUTION.—5 P.M. General Monthly Meeting.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—8 P.M. Casual communications by Messrs. A. Winterbottom, F. Henri Weiss, T. Ackery, A. S. Underwood, C. Vincent Cotterell, and W. Harrison (Brighton). Dr. Dudley Buxton: Physiological Action of Nitrous Oxide Gas.

SOCIETY OF ARTS.—8 P.M. Mr. W. Y. Dent: Building Materials (Cantor Lecture).

MEDICAL SOCIETY OF LONDON.—8.30 P.M. General Meeting for Election of Officers and Council.—Mr. Marmaduke Sheild: On a case of Perforation of Femoral Artery and Vein by Ulceration; Ligature of both Vessels.

Tuesday, March 8.

GUY'S HOSPITAL.—Operations, 1.30 P.M. and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 1.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M.

ROYAL INSTITUTION.—3 P.M. Prof. Gamgee: Function of Respiration.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. Mac Alister: The Nature of Fever (Gulstonian Lecture).

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Dr. Debout d'Estrées: On Gouty Parotitis and Gouty Orchitis (communicated by Dr. Garrod).—Dr. W. Bwart and Mr. R. F. Benham: Case of Empyema with Pulmonary Gangrene following Enteric Fever, treated by Perfiation.

Wednesday, March 9.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.

CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M.; Saturday, same hour.

SOCIETY OF ARTS.—8 P.M. Mr. William P. Marshall: Railway Brakes.

EPIDEMIOLOGICAL SOCIETY OF LONDON.—8 P.M. Dr. S. Mackenzie (for Dr. W. Myers): Filaria Sanguinis Hominis in South Formosa.

HUNTERIAN SOCIETY.—8 P.M. Dr. Horrocks: Cases of Uterine Tumour accompanied by Pyrexia.—Dr. Turner: Actinomycosis.

ROYAL MICROSCOPICAL SOCIETY.—8 P.M. Mr. G. Massee: On the Differentiation of Tissues in Fungi.—Dr. H. J. Johnston-Lavis and Dr. G. C. J. Vosmaer: On Section-cutting of Sponges, &c.

BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Exhibition of Specimens. Dr. Purcell: On Three cases of Vaginal Hysterectomy.

Thursday, March 10.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Ophthalmic Operations, Friday, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION.—3 P.M. Mr. Edmund Gosse: The Critics of the Age of Anne.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. Mac Alister: The Nature of Fever (Gulstonian Lecture).

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.—8.30 P.M. Living and Card Specimens at 8 P.M.:—Dr. C. B. Beevor: Ophthalmoplegia Externa without any other symptoms.—Dr. Sidney Phillips (introduced): Case of Peculiar Associated Movement of Upper Lid.—Mr. Brudenell Carter: (1) Case of Large Spontaneous Hæmorrhage into the Vitreous in a young man; (2) Painting executed by an artist after Cataract Extraction.—Mr. J. G. Mackinlay: Paralysis of both External Recti.—Mr. Karop (introduced): Fibroid Degeneration of Ciliary Muscle.—Mr. Marcus Gunn: Pupillary Movement in Association with Lateral Deviation of Eyeballs. Papers:—Dr. Brailey and Mr. Hartley: Tubercular Disease of Choroid.—Mr. Simeon Snell: Treatment in Sclerotic Wounds.—Dr. Gowers: On Conjugate Ocular Palsy with Nystagmus.—Mr. Jessop: Sudden and Lasting Lateral Nystagmus.—Mr. Nettleship: Night-blindness with Peculiar Retinal Changes.

Friday, March 11.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

CLINICAL SOCIETY OF LONDON.—8.30 P.M. Dr. de Havilland Hall: On Pneumothorax occurring in Persons apparently Healthy.—Mr. Hve: On a case of Intra-peritoneal Excision of the Rectum, with recovery.—Mr. Keetley: A case of Scoliosis.—Mr. Davies-Colley: A case of Contraction of the Metatarso-phalangeal Joint of the Great Toe.

ROYAL INSTITUTION.—9 P.M. Archdeacon Farrar: Society in the 4th Century A.D.

Saturday, March 12.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—3 P.M. The Rt. Hon. Lord Rayleigh: On Sound.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE SCHOOL OF SALERNO.

E. C. (Glasgow).—The important place held by this seat of learning in the annals of the healing art could not be better stated than in the words of Dr. Salvatore De Renzi, the distinguished physician and scholar of Naples, whose "Collectio Salernitana" (Naples, five vols. 8vo, 1852–59) is a monument of industry and judgment. "The School of Salerno," he says in his introduction, "has laid the whole world of medicine under heavy obligations. First and greatest among its services, it has preserved the tradition of the Græco-Latin medicine in disorganised and calamitous times, during which the antique civilisation had fallen under the brutal sway of nomadic invaders, and science and literature had sunk into oblivion. Secondly, it reared the first Christian institution in the West when the sciences, having become Mahometan, were constrained to seek shelter under the ægis of the enemies most fatal to them. Thirdly, it laid deep the foundations of modern universities, reconstituting medicine as a part of the whole civil order, and establishing public hygiene on new and solid bases. Fourthly, it enriched by special contributions the scientific heritage bequeathed by our forefathers. Fifthly, it was the source and centre whence instruction in the healing art was diffused over all Europe, so contributing to evoke the scientific renaissance. Sixthly and finally, it fulfilled a noble mission of the Italian people—that of making themselves the custodians of the intellectual palladium, and preserving for them the glory of endowing the world a second time with civilisation." Dr. De Renzi's argument, it will be seen, is pitched high; but we have only to peruse faithfully the documents he has put together, with the aid of the German Henschel and the French Daremberg, to justify, and even to share, his enthusiasm.

Country Assistant asks if someone will suggest the microscopical specimens necessary for the Triple Edinburgh, also where they can be procured.

RAYNAUD'S DISEASE IN ADULT LIFE.

To the Editors of THE LANCET.

SIRS,—In your issue of Jan. 29th Dr. Seymour Taylor describes a case of Raynaud's disease in an adult female, which he states is exceptional. Last year I had a case in a woman aged fifty-six. She is still under my observation. Should Dr. Seymour Taylor wish for any particulars of the case, I shall be very pleased to give them if he will communicate with me.

I am, Sirs, yours faithfully,

Haverhill, Essex, Feb. 26th, 1887. B. L. TANDY.

CREMATION.

THIS method of disposing of the dead finds no favour from the Roman Catholic Church, which has recently denounced it in prose and verse. Monsignor Giovannini, theological canon of the arch-diocese of Bologna, has published a special treatise against it, and the treatise, in turn, forms the subject of the following epigram from the pen of Prof. D. Vincenzo Tavozzi:—

"Quam scite ustrinum damnas, et sacra sepulcri,
Digna vel humano pectore, jura tenes.
Ut tua scripta amet indoctus doctusque, Leonis
Jussaque Pontificis firmius usque probet."

("So wisely 'gainst cremation you defend
Man's sacred right to sepulture, that all—
Learn'd and unlearn'd alike—your work extol,
And keep Pope Leo's mandates to the end.")

Professor Tavozzi has more than metrical reasons for using the word *ustrinum*, instead of the modern and needless coinage *crematorium*. On the other hand, his *tuâ scripta* (the short vowel before *sc*) is a collocation which "ought never to be introduced into modern Latin poetry" (Ramsay's Latin Prosody, p. 280).

Mr. Reginald Pollard.—The announcement appeared in our issue of the 12th ult.

THE VOLUNTEER MEDICAL SERVICE IN PEACE AND WAR.

To the Editors of THE LANCET.

SIRS,—I quite agree with the substance of the remarks in your issue of February 19th by Dr. W. P. Mears on this subject. I must state, however, that in connexion with the 1st Volunteer Battalion Royal Warwickshire Regiment the physical fitness of recruits is insisted upon before enrolment, the medical officers attending every week, when recruits present themselves, who are subjected to a rigid medical examination on army lines, to the number of about 300 each year. This system has now been in vogue about three years, and has resulted in a marked improvement in the physique of the men. I may also mention that we are invariably consulted on sanitary and other medico-military matters, although, as Dr. Mears states, these matters are not insisted on by the War Office authorities, and are simply the result of good feeling between the combatant and medical officers. We have also a well-drilled department of regimental bearers (two per company), and our own ambulance-waggon (Mark 3), and stores—as stretchers, water-bottles, haversacks, &c. This work is, I am glad to say, being taken up by many other battalions in the Midlands, mainly owing to the Midland Volunteer Medical Association, which has been formed for that purpose, and in connexion with which an annual field-day is held at one of the regimental camps. I think that such an association in other centres would have a very good effect in developing an interest in ambulance work. In conclusion, I quite endorse the opinion of Dr. Mears that many of us are deterred from attending schools of instruction, and passing the necessary examinations, by the fact that we do not receive pay. The expenses, which are already much heavier than those of combatant officers attending schools, are rendered deterrent in consequence of the additional strain involved.

I remain, Sirs, your obedient servant,

EDWARD L. FREER,
Acting Surgeon, 1st Vol. Batt. Royal Warwickshire Regt.,
Hon. Sec., Midland Vol. Medical Association.

Birmingham, Feb. 21st, 1887.

SPONTANEOUS DISAPPEARANCE OF A TUMOUR IN THE PAROTID REGION.

To the Editors of THE LANCET.

SIRS,—In an article on "Surgical Mishaps" by Mr. T. Pridgin Teale, in your issue of January 1st, mention is made of the disappearance of a tumour in the parotid region after ineffectual attempts to remove it. In November, 1885, I operated with the intention of removing a tumour the size of a walnut from the parotid region, on a child three years of age. It had been growing a year, and latterly very fast, was elastic and quite movable. On cutting down I found it had no capsule, and was very adherent to the muscles and fascia. I made a second incision backward towards the mastoid, and attempted to enucleate it, but the deep attachments were so firm and the bleeding so free, that I was forced to desist, after ligating a number of vessels on both posterior and anterior sides of tumour. The wound healed promptly, and I saw no more of the case until October, 1886, when I was called to see another member of the family. On asking for the child, the mother informed me that about two months after the operation she noticed that the lump was smaller, that it continued to decrease, until at that date no trace of it remained except the operation scars. I attributed its disappearance to the cutting off of the blood-supply.—I am, Sirs, your faithfully,

Fredericton, N.B., Canada. G. H. COBURN, M.D.

PARALDEHYDE.

To the Editors of THE LANCET.

SIRS,—Will any of your many readers who may have prescribed paraldehyde kindly give their experiences of its effects?

I am, Sirs, yours truly,

March 2nd, 1887. SUBSCRIBER.

Digitized by Google

THE MEDICAL PROFESSION AND LIFE ASSURANCE OFFICES.

DR. THURSFIELD presents his compliments to the Editors of THE LANCET, and asks for the insertion in that journal of the enclosed circular and the correspondence in connexion therewith, as it is of importance to life assurance offices as well as to the profession.

"National Life Assurance Society,
"2, King William-st., E.C., Feb. 14th, 1887.

"Dear Sir,—My directors have found it necessary to reconsider the scale of fees for medical examination of lives proposed for insurance, as many cases, after examination, are not completed, and the fee of 21*s.* is a very heavy charge upon the small assurances, even when they are completed; and the following scale has been adopted:—For assurances under £500, a fee of 10*s.* 6*d.*; of £500 and upwards, 21*s.*; when the premiums are payable monthly, a fee of 10*s.* in each case, except when the monthly premium is under 10*s.*, when the fee will be 5*s.* My directors believe that these are the fees usually paid in such cases, and I shall be glad to hear whether you are willing to accept them.

"I am, dear Sir, yours faithfully,
"Dr. W. Thursfield." "H. J. PUCKLE, Manager and Secretary.

"39, High-street, Bridgnorth, Feb. 16th, 1887.

"Dear Sir,—Your directors may have good reasons for reconsidering the scale of fees for medical examinations; but when they ask the profession to adopt their scheme, I would ask, Are they prepared to reduce the number of questions at each examination in proportion to the reduction in fees; or do they expect us to answer for 5*s.* what formerly they were willing to pay a guinea for? And will they issue a sliding scale in the ascendant, and pay a guinea for each £1000 insured for? When they deal thus with the profession they may expect us to acquiesce in the arrangement; not otherwise. To my mind, the amount insured for has, and should have, nothing to do with the medical referee. He has simply to do his duty by examining the person to be insured, and it takes him as long, and gives as much trouble (and very often offence), to do it for £100 as for £5000. As this matter is of importance to the profession, I am sending your circular and my reply to THE LANCET for insertion. "I am, dear Sir, sincerely yours,
"H. J. Puckle, Esq." "W. THURSFIELD, M.D.

"National Life Assurance Society,
"2, King William-st., E.C., Feb. 17th, 1887.

"Dear Sir,—I have received your letter of the 16th inst., and have had an opportunity of submitting it to the President of this Society, who expresses his surprise that you should think of sending our circular and your reply to THE LANCET without consulting us. In answer to your inquiry, I beg leave to state that we do *not* expect you to answer for 5*s.* what formerly we were willing to pay a guinea for. My directors have recently decided to grant assurances at monthly premiums, with a view to making the payments easier for those to whom the payment of yearly premiums would be inconvenient. The average amount of these assurances will probably be considerably smaller than in the case of assurances at annual premiums, and for them a simplified form of medical examiner's report has been specially drawn up. Of this I enclose you a copy. I think it is obvious on very slight consideraton that an office cannot possibly afford to pay guinea fees for business of that description. With regard to the further question as to a sliding scale, I do not think that there will be any objection to paying a guinea for each £1000 assured—that is to say, taking the large and small cases together, we should, I think, be prepared to pay at the rate of a guinea per £1000 at quarterly or half-yearly intervals, as may be arranged. If you have sent our circular and your reply to THE LANCET, you will probably see the propriety of sending this letter also for publication.

"I am, dear Sir, yours faithfully,
"H. J. PUCKLE, Manager and Secretary.
"W. Thursfield, Esq., M.D."

"39, High-street, Bridgnorth, Feb. 18th, 1887.

"Dear Sir,—Unsolicited you sent me on the 16th inst. a printed circular, which your directors had authorised you to do. It was, I suppose, sent to others as well as me. It was not marked "private and confidential"; and as it was important to the profession, I deemed it worthy of discussion in the medical press. Hence my action. I cannot see what cause of complaint you have against me for doing so. Publicity in such matters is good for all. It is a pity you did not enclose with your circular what you call the "simplified form of medical examiner's report" (for 5*s.*). Why when sending it yesterday did you omit to send the guinea report for comparison? The one you sent is pretty exhaustive for the money, including, as it does, urine testing and personal examination inside and out. I do not think you will find medical examiners enamoured with your plan of paying ascending fees in dribblets, quarterly or half-yearly. I contend for a guinea in all cases, the amount of assurance having nothing to do with the duties of the examiner. I will, as you wish, forward this correspondence to THE LANCET.

"I am, dear Sir, sincerely yours,
"H. J. Puckle, Esq." W. THURSFIELD, M.D.

"THE STABILITY OF THE EARTH."

THE recent frightful convulsion in the South of Europe renders an article with the above title, by Professor N. S. Shaler, published in *Scribner's Magazine* for March, peculiarly interesting and opportune. The writer describes the causes, distribution, and effects of earthquakes and cognate phenomena, and offers suggestions as to the best methods of preparing for them and avoiding the perils they occasion. The article is illustrated by several excellent engravings.

NIGHTMARE.

To the Editors of THE LANCET.

SIRS,—I would suggest to "M.D." that he have his heart and aorta carefully examined by some experienced friend; and, if he be a smoker I should advise him to give up tobacco altogether.

I am, Sirs, yours faithfully,
February, 1887. T. B.

VIVISECTION.

Physiologus.—Whether, or to what extent, vivisection is justifiable forms a theme of discussion as old as medical history. Celsus drew the line at the anatomy of the living (human) subject, and condemned as "crudele et supervacuum" the dissections performed by Herophilus and Erasistratus on live criminals who were handed over to them by reigning monarchs for the purposes of science. The wounds inflicted on gladiators in the arena, on soldiers in the field of battle, on travellers at the hands of highwaymen, sometimes exposed the internal parts, and the anatomist (he held) was quite warranted in making the most of such opportunities. On the other hand, the "Father of Inductive Research" says, in Book iv. of the "De Augmentis": "It is no less true (as was antiently noted) that many of the more subtle passages, pores, and pertusions appear not in anatomical dissections, because they are shut and latent in dead bodies, though they be open and manifest in live. Wherefore, that utility may be considered as well as humanity, the anatomy of the living subject is not to be relinquished altogether, nor referred (as it was by Celsus) to the casual practices of surgery; since it may be well discharged by the dissection of beasts alive, which, notwithstanding the dissimilitude of their parts to human, may, with the help of a little judgment, sufficiently satisfy this inquiry." Bacon's latest and best editor, Mr. Robert Leslie Ellis, in giving a guarded opinion on this passage, omits to notice that it was written before the discovery and application of anæsthetics.

Mr. W. K. Gould.—The specimen of the valuable powdered root might be submitted for experimentation, say, to Prof. Fraser, or Dr. Ringer, or Mr. Victor Horsley, if it is desired to have its efficacy tested in hydrophobia.

Mr. G. Steel Scott, M.B.—Our correspondent must be guided by the advice of his solicitor.

FRACTURE OF THE THIGH DURING PARTURITION.

To the Editors of THE LANCET.

SIRS,—Three weeks ago I attended J. C—— in her fifth confinement. It was a natural vertex labour in first position. After the birth of the head I had only just time to tell her to take it easy till another pain came, when the shoulders and body followed. As they were coming I heard a snap, which, had she been a primipara, I should have put down to rupture of the perineum. The true cause was at once evident in the fracture of the left thigh. I was naturally rather dismayed at the probable difficulties of treatment, fearing that I should soon have a broken skin in addition to the broken thigh, and not knowing at all how to set about keeping the latter quiet. However, after a little consideration, it struck me that the most natural position would be that which had been in utero—doubled up on the abdomen. I therefore put a turn of Gamgee tissue round the thigh, and two or three turns of soft bandage round that; then, after dressing the stump of the cord and confining that in a belly-band as usual, I procured another belly-band broad enough to reach from the lower part of the abdomen to the middle of the thorax, cut a hole in the centre of it large enough to slip the foot and lower leg through, and by this means bound the thigh pretty securely against the abdominal wall, the foot and leg below the knee hanging out of the middle of this second belly-band. Besides this, I further controlled the movement of the lower leg by telling the nurse always to confine it entirely inside the ordinary napkin. The dressing has been entirely changed every other day only, and there is now considerable firmness of the broken bone, with very good position, though, of course, a good deal of thickening. The skin has been kept sound, which I think would hardly have been the case had any stiff material been used as a splint.

I should be obliged if any of your readers would comment on the case as to the probable cause of the fracture. The only thing that struck me about the birth was the very marked and very quick rotation of the face to the mother's right thigh after the escape of the head. The child thrives, and seems quite healthy. I am, Sirs, yours faithfully,
Feb. 28th, 1887. Æ.

Mr. T. Laffan.—The correspondence is printed in the Minutes of the General Medical Council. We regret our inability to reproduce it in our columns.

M.D. (*Erlangen*) is referred to our advertising columns.

MR. ASH'S METHOD OF SEWER VENTILATION.

To the Editors of THE LANCET.

SIRS,—Accept my sincere thanks for the article in your valuable and highly esteemed journal on my invention for sewer ventilation. At the same time I beg to point out to your notice a slight mistake in the wording that may give to the general public a very wrong conception, as you will readily perceive. In my specification I claim (1) the method or system of ventilating by means of the ignition and explosion of gas or other suitable substance or compound producing an explosion at certain intervals and at determined points or situations in the structures to be ventilated, and (2) the construction of an apparatus where coal-gas can be applied to produce explosions. The man-holes are generally placed where it would be impossible to have explosions.

I am, Sirs, your obedient servant,
Monaco, Feb. 18th, 1887. ROBERT S. ASH.

THE ANCOATS HOSPITAL.

Mr. E. Stanmore Bishop, F.R.C.S., referring to a note in our last issue by our Manchester correspondent on the Ancoats Hospital, states that there has never been the slightest wish on the part of the governors of that institution to trespass upon the domain of the Children's Hospital, or interfere with the work so well done by it. What it is desired and intended to do is to develop its resources as a general hospital in a district which, perhaps more than any other, requires one; and this object will be effected by obtaining a women's ward for medical cases, so that they need no longer be treated with the surgical ones, and the constant demand for women's beds may be fairly met.

"OBSTINATE CONSTIPATION IN AN INFANT."

To the Editors of THE LANCET.

SIRS,—I can fully bear out the statements of Dr. Lucas as to the efficacy of massage in the treatment of constipation in infants. It is a most potent and reliable remedy. I have at present an infant under my care that has suffered from constipation since its birth, seven weeks ago. During that time there had not been a single natural motion, and enemata had to be resorted to, sometimes twice daily. The usual medicines were tried as well, but with very indifferent results. About a fortnight ago these remedies were altogether discarded, and massage resorted to. In less than a week the infant was quite cured of the constipation, and, in fact, erred in the opposite way. The motions also lost their very offensive character, and became quite natural. I lay particular stress on the mode in which the "rubbing" should be done, and am inclined to think that it may prove a source of danger in untrained hands. I am, Sirs, yours faithfully,

Ben Rhydding, March 1st, 1887. T. GERALD GARRY, M.D., M.Ch.

To the Editors of THE LANCET.

SIRS,—In reply to your correspondent, "O. P. Q.," in your issue of Jan. 29th, I would advise him to try simple wheat bran for the constipation. This is a very simple remedy, but in my hands it has done more than any drug or combination of drugs that I have ever tried. It is becoming quite a popular remedy for habitual constipation in the United States. I am afraid your readers may treat it as one of old treated the instructions to wash seven times in the river Jordan; but I can assure them that if they try it they will be well repaid in the results. For an adult I usually direct a tablespoonful to be taken in milk or water at bedtime. If necessary, it may be taken twice or three times during the day. I would recommend your correspondent to give a teaspoonful twice or three times a day, in any way possible to get the child to take it. I am, Sirs, yours faithfully,

Lincoln, Neb., U.S.A., Feb. 14th, 1887. G. H. SIMMONS, M.D.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Julius Pollock, London; Dr. W. C. Maclean, Southampton; Dr. Donald Mac Alister, Cambridge; Mr. J. Gulstonian Lectures
ON THE
NATURE OF FEVER.

Delivered at the Royal College of Physicians,

BY D. MACALISTER, M.A., M.D., F.R.C.P.,
PHYSICIAN TO ADDENBROOKE'S HOSPITAL, LECTURER IN MEDICINE AT THE UNIVERSITY OF CAMBRIDGE.

LECTURE I.

MR. PRESIDENT AND GENTLEMEN,—I have at the outset to acknowledge the goodwill of our much-esteemed President, which led him to invite me, one of the four junior Fellows of the College, to assume the exacting office of Gulstonian lecturer. The distinction of the audience to be addressed, and the high standard of excellence upheld by previous lecturers, make the office exacting indeed. Had I not understood that the invitation to undertake it had in it something Royal, and was almost a command, I would have shrunk from inflicting my crude reflections and my profound inexperience on your practised ears. But when I considered that you would probably not look for maturity or experience from one who is literally a junior Fellow in every sense, when I was assured that your tolerance of youthful effort was large and kindly, I took heart and ventured to announce this course of lectures. Fortunately for me, a wide latitude in the choice of a subject and in the manner of treating it has hitherto been permitted. My term of practice has been far too short to enable me to offer you any generalisation based on extensive clinical work or on ripe knowledge of human nature, such as has in late years delighted and instructed you. My aim must perforce be humbler. I must be content with attempting to coördinate certain recent advances in our knowledge concerning a department of pure pathology, and with suggesting to you certain lines along which it is possible that further advances may be made.

My subject is the Nature of Fever, and though I did not choose it light-heartedly, it was only when I came to set down my ideas upon it that I fully appreciated all its difficulty. Still, inasmuch as for the last five or six years it has never been long absent from my thoughts, and as its problems, physical and physiological, have constantly exercised me, I may be pardoned if I venture to discourse on a subject in one aspect so familiar and fundamental, in another aspect so little understood. Our knowledge of the clinical aspect of fever is now singularly full. I can add little or nothing on this side. But that the intimate nature of the febrile process—its morbid physiology, so to speak—is not understood, we have sufficient evidence in the diverse and contradictory explanations offered in our medical text-books. From time to time, and chiefly at present from the Continent, we are receiving fragmentary solutions of some of the outstanding questions that present themselves to the investigator of fever. These often come from workers who have no thought of the pathological problem they are unwittingly helping to solve. They appear under various guises and in many journals. The busy physician cannot hope to notice them all, or to recognise their bearing on his needs. He may therefore welcome an attempt to bring together their results, which are apt to be buried under a mass of experimental detail, and to appraise their value as contributions to the general subject. My literary work for some years has obliged me to survey much of recent pathological literature, and it is on that ground only that I can hope to offer you some matters for consideration that are perhaps not known to all. That much of what I have to say is already familiar to some of my audience is certain. If I say it notwithstanding, it is because I wish to be clear and complete rather than original.

In the first place it is necessary to state what I mean by *fever*. I need hardly say that I do not refer to the specific infective diseases grouped together as the "eruptive" or "continued" fevers. I speak of the condition of feverishness or pyrexia which is common to these diseases and to many others—the disordered inward condition of the body heat, whose frequent and most manifest outward sign is high temperature. It is of course true that the term "fever" conveys to our mind a more complex notion—it implies, in general, disorder of the circulation and the respiration, of secretion and digestion, of the nervous system and the muscular system, as well as of the body heat. But without saying, as some *have* said, that all the other disorders of function which we describe as febrile are merely consequences of the disorder of temperature, I shall not be going too far if I state at the outset that the *essential* fact in fever—the condition which is always present whether other of its symptoms are present or absent—is disorder of the body heat. In using the word "essential" rather than "primary," I wish to avoid the pre-judgment suggested by the latter. Other conditions may precede in time or in causation the essential symptom of disordered heat, and according to the confidence or the refinement of our analysis we may term one or another of them primary, but not until the essential symptom is present have we to do with fever. We have a like state of things in the case of *inflammation*. The single word covers a whole series of processes; each process is a complex of many elements. It implies changes textural and changes vascular, changes nervous and changes mechanical. And in the gradual development of pathological knowledge now one and now another of these has been regarded as *primary*. But to-day we are justified in holding, for the reasons so admirably set forth by your Lumleian lecturer in 1882, that alteration or damage of the minuter bloodvessels is the *essential* condition, without which there is no inflammation.

Disorder of the body heat, then, is the essential condition of fever. To understand the nature of fever we must examine the nature of this disorder. But first it is necessary to consider the natural ordering of the body heat, the healthy function of which pyrexia is a disturbance. The constancy of the temperature of the body in health, under widely varying internal and external conditions, is a fact so familiar that we have ceased to wonder at it. Yet it rests on a perpetual balance of opposing tendencies which is as mysterious and as beautiful as anything in our frame. As a mere question of physics, the maintenance of a constant temperature by a body plunged in a cooler and variable medium like the air involves three coöperant factors. There must be a source whence heat is produced, whether at a uniform or at a variable rate. There must be processes by which heat is discharged from the body or transformed within it. There must be a mechanism by which the heat production and the heat loss are balanced at the normal height. This mechanism must be in relation on the one hand with the processes of heat production, and on the other hand with those of heat loss. And its relations with these must be so intimate that within limits the balance it maintains shall be not only steady, but *stable*. In other words, small deviations from the normal temperature in either direction must call into play thermal tendencies whose resultant is back towards the normal. Increased loss must be promptly compensated by increased production, and increased production met by increased loss. This *stability* is to be distinguished from the property of mere steadiness or constancy, though, of course, the two are connected. In health, as we all know, there are daily fluctuations of a regular kind, and these must be borne in mind when we speak of the temperature of the body as constant. The constancy, so far, is imperfect. But in health the stability of the temperature is nearly perfect. A very short time suffices to overcome the disturbance produced by change in the external thermal conditions. And in like manner the consumption of a large amount of physiological fuel (i.e., food), and the internal production of heat thereby originated, has only a transient influence on the surface temperature. If we may use Greek terms, we might say that man, with other "warm-blooded" animals, is not only *homœothermic*, but *thermostatic*. We shall have occasion to refer to this distinction when we come to consider a theory of fever which has found some acceptance among us.

The mechanism which regulates the body temperature and gives it stability, as the governor of a steam-engine regulates the speed, we speak of briefly as the thermotaxic mechanism. When we reflect on the promptness of its action, on its sensitiveness, on the amount and variety of the substance whose thermal variations it has to control and adjust, we cannot resist the conviction that the mechanism is nervous.

Digitized by Google

as we go on we shall find numerous reasons in support of this conviction. It is when we come to consider the exact nature of this thermotaxic nervous mechanism that difficulties arise. Where is the seat of the coördinating power? Is its action direct or indirect? Does it control temperature chiefly by varying heat production, as when we raise or lower the flame of a gas stove or the damper of a furnace flue? or by varying the heat loss, as when we open or close the window of a heated room? These are questions of physiology, but their solution is in a sense the solution of the problems of fever; and no fruitful discussion of *its* pathology can take place if they are not carefully dealt with, and their scope at least understood.

It is clear that, given a steady and fairly uniform production of heat, regulation might to some extent be effected by a mechanism controlling only the loss of heat from the body. It is as clear that, given a steady rate of heat loss, a mechanism controlling the production of heat would also suffice to regulate the temperature. But we have abundant reason for believing that neither the production of heat nor the loss of it is even approximately steady in healthy active life, and therefore for believing that both these controlling mechanisms are necessary and in fact exist. The thermotaxic mechanism is, in Dr. Hughlings Jackson's sense, "higher" than either of them. It governs them both; it adjusts their mutual relations. It is later in attaining its full development, and it is more liable to fail under injury or disease. We shall see that the mechanism controlling heat production comes next in functional order, while that controlling heat loss is lowest of the three. Now, it happens not unnaturally that our knowledge of these mechanisms is least as regards the highest and greatest as regards the lowest; and as each has its special bearings on the process of fever, I shall subdivide my discourse into three parts having reference (1) to heat loss, (2) to heat production, and (3) to the thermotaxic nervous mechanism. I shall thus proceed from the better known to the less, in the hope that in passing from the certain to the probable and thence to the possible I may not wholly fail in carrying you with me.

First, then, as to heat loss and its relations to the process of fever. The main channels by which heat passes out of the body to its environment are of course the skin and the lungs. Through the skin in health by evaporation, conduction, and radiation there escapes more than 80 per cent. of all the heat discharged. In warming and moistening the breath less (perhaps much less) than 20 per cent. escapes. The rate of loss is varied, as we know, by alterations in the vascularity of the skin and in the period and amplitude of the respirations. A face flushed with wine feels warm, for it is rapidly discharging heat; a dog, whose skin lets little heat pass through, pants to cool itself. Experiment and observation have established the existence in the brain and spinal cord of vaso-motor "centres" that control the blood-supply of the integuments by varying the calibre of the arteries. The efferent nerves that pass from these centres to the vessel walls are of two kinds: the one vaso-constrictor, or, as we may say, motor; the other vaso-dilator, or inhibitory. The "centres," whatever meaning be given to the term, must themselves have something corresponding to this twofold differentiation. In like manner the rate of respiration is governed by a nervous mechanism, consisting of centres in the medulla and cord, with a twofold complement of nerves proceeding to the respiratory muscles. There are strong grounds for regarding these nerves also as respectively motor and inhibitory, and the respiratory centre as consisting of two correlated parts, one subserving inspiration, the other checking inspiratory movement and subserving expiration. The channels of heat dissipation are thus admittedly under the control of nervous mechanisms, twofold or double-acting mechanisms we might say, each having a motor and an inhibitory aspect. Moreover, these mechanisms are known to be susceptible to rise of temperature, reacting thereto in such a way that the resulting vascular and respiratory changes increase the discharge of heat from the body. Attracted by the apparent simplicity of these arrangements for the governance of heat loss, it is not wonderful that Traube should have sought to base on them a theory of thermotaxis, and of that derangement of thermotaxis whose manifestation is pyrexia. "In health," he would say, "the temperature of the body is maintained by the vigilant action of the sensitive nerve centres that control the great systemic functions of circulation and respiration. Fever is due primarily to a disorder of these centres, by which the normal rate of discharge is diminished heat is thus pent up within the tissues, and their temperature rises by 'retention.' This general rise of temperature then reacts on the organs to their hurt, and the disorders of secretion and nutrition, which we know as febrile, naturally follow." No explanation could well have been more simple, and it was applied with much skill to account in a natural way for many of the clinical features of pyrexia. Irritation of the vaso-motor centres by injury or poison led to prompt and abiding spasm of the arterioles of the skin. When the centres were very irritable or the irritant intense, the resulting rise of temperature was rapid. The sudden difference thus caused between the temperature of the peripheral ischæmic parts and that of the central parts acted as a powerful sensory stimulus, and this by a reflex action set up a powerful motor disturbance—the initial *rigor*. When the spasm of the arterioles suddenly relaxed, a gush of heat took place from the fevered body, and its temperature fell by *crisis;* when the spasm yielded gradually and with intermissions, we had a *lysis*. It is not wonderful, I say, that observers like Traube and Marey, whose labours on the mechanism of circulation and respiration had been so great and so fruitful, should favour this "retention theory." It rested on their own work, it involved only mechanisms with which they were intimately acquainted, it was apparently capable of wide application to clinical facts, and it was partially true. And so long as certain other facts were unknown or ignored, the theory certainly satisfied many acute observers, and even now appears in some of our medical text-books as the last word of physiological pathology.

Let us consider, then, the *retention theory* of Traube, and examine wherein it fails. "Pyrexia is due to a diminished discharge of heat from the surface of the body, and this to a powerful contraction of the arterioles of the skin." It is plain that the structure rests on the one fundamental assumption—namely, that the escape of heat from the body is unduly small. If that assumption is itself unfounded, we have no choice but to conclude that, though retention may be a *vera causa* of fever, it is not the essential cause. Twenty years ago experiments were made to test the assumption. Inasmuch as the question is one of quantities of heat and not of temperature only, it was clear from the outset that the test must be calorimetrical, not thermometrical. In other words, the heat passing from the fevered body must be measured by the mass of water (say) it is capable of warming to a measured extent. This quantity of heat must then be compared with that given out by the normal body under like conditions. The first attempts, made by Liebermeister and others, were open to objections of many kinds, physical as well as physiological. Professor Burdon Sanderson has subjected some of them to criticism, sometimes more severe than they quite deserve, in his excellent memoir on the "Process of Fever," published as a Government paper in 1875. Thus Liebermeister placed a fevered patient in a tepid bath, and noted the amount by which the water was heated in a given time. But the experiment was vitiated as a quantitative test by the changed physiological conditions the contact of the water might cause in the patient's body, and by the fact that the powerful heat-discharging process of evaporation was interfered with. Leyden and Senator, with greater precautions, measured the heat discharge from fevered limbs and from fevered animals. In the case of the latter, means were found for estimating the quantity of carbonic acid and the quantity of watery vapour exhaled in a given time. Pains were taken to compare the results with those yielded by a normal animal under like conditions as regards food. The net result was to show that both in the human patient and in the fevered animal pyrexia was accompanied not by *diminished* but by *increased* discharge of heat. Senator, indeed, goes so far as to estimate the average increase of heat loss in some cases of septicæmic pyrexia at something like 75 per cent. The objections that have been raised to the methods employed touch, as I have hinted, rather the quantitative than the qualitative value of these calorimetric tests. The latter is not at all ambiguous: the increased discharge of heat was unmistakable. Like experiments have been repeated in recent years by Wood of Philadelphia, and by Reichert and Hare under his direction. Their arrangements were admirably designed, the criticisms of 1875 were considered and met, and the work bears every mark of honesty and care. From a physical point of view there seems nothing to which objection can be taken; and the outcome of the last measurements, published only the other day, is the same as that of the older and less perfect

Digitized by Google

once of fifteen years ago. It is that heat is *not* abnormally retained in the body during fever; on the contrary, it is excessively discharged: and this is true not of one stage only; it holds for the rise and for the continuance of the fever, as well as for its fall.

This foundation of the retention theory being done away, the theory falls to the ground as an adequate explanation. But we may further ask—Is it indeed a fact that during fever there is an abiding spasm or tetanus of the arterioles of the skin? This question has been minutely investigated, and though the answer is decidedly in the negative, the research has added largely to our understanding of some of the phenomena of fever. Clinical observation prepares us to believe that the cutaneous circulation may vary greatly during the same febrile attack. At one time the skin is pale and dry, at another flushed, at another bathed in perspiration. Direct observation of the vessels, say in the ear of a fevered rabbit, shows that their calibre is constantly altering in a way that is quite different from the quasi-rhythmical contraction and dilatation of health. These changes become irregular and excessive, so that the surface is within an hour or two pale and cool, then intensely hot and hyperæmic, and then pale once more, the body temperature remaining all the while at a febrile height. Less direct, but perhaps not less convincing, is the evidence afforded by the surface temperature. Whatever spot of the skin we choose, and in whatever variety of fever, we find that the surface temperature fluctuates from hour to hour in a remarkable manner, the curve representing its changes having little or nothing in common with the rectal temperature. Of this my own observations have repeatedly convinced me.

From all these facts, and I have only touched on them in the most general way, we gather that in fever the cutaneous vessels are *not* in a state of continuous contraction. The cutaneous blood-supply, on the contrary, fluctuates in an irregular manner: now flushing the surface tissues, raising their temperature, and pouring out heat into the air; now reduced to a minimum, leaving the skin pale and dry, and shutting in the heat of the central parts. All this, of course, betokens that the nervous mechanism which controls the cutaneous discharge of heat is notably disordered. There is, indeed, no constant stimulation of the vaso-constrictor nerves such as Traube imagined; there is no continuous retention of heat, but there are marked irregularities in the rate at which it is discharged. These irregularities have doubtless much to do with determining the type of the febrile temperature, the configuration of the charts, in various diseases. But they leave out-standing and unexplained the two cardinal facts—first, that the febrile discharge of heat is greater than the normal discharge, and, second, that notwithstanding this greater loss the temperature so often rises and remains high. One possibility only remains—namely, that the production of heat within the body is abnormally increased.

The next question that suggests itself is this—Is the heat production steady, or is it fluctuating? We have seen that the heat loss, as gauged by the condition of the surface, is subject to wide and irregular variations, not merely from day to day during the course of the fever, but even from hour to hour in the same day. Is there any similar irregularity in the rate of heat production? To answer this question we must again fall back on calorimetry. Thermometrical observations are of no service. The daily balance at my banker's tells me nothing of the variations in my receipts. It depends on out-goings as well as in-comings. The temperature of the body is merely a function of the difference between heat income and heat expenditure at any moment. Now, we cannot well shut up a fever patient in a calorimeter for hours or days together, so our direct knowledge of variations in human heat production during fever is of the slightest. We must have recourse to experiments on animals. The only recent investigations which have been conducted with a view to directly answering our question are those of Wood and his assistants. An examination of their numerical results shows that in the septicæmic fever of dogs and rabbits the hourly rate of heat-production does vary in a remarkable way, even under uniform conditions as to feeding or fasting. The variation shows in some animals a tendency to rhythm, being usually higher towards the evening. Feeding introduces a marked increase of heat-production in the normal animal, and the increase is not absent in fever. Further experiments are to be desired, but of the mere fact of fluctuation in heat production there seems no doubt. Some of the figures, morever, show that, as the course of the temperature varies, the rate of heat production may actually be highest when the temperature is lowest: an excessive rate of heat loss may overbear and so disguise a simultaneous excessive rate of heat production. And, conversely, the time when the temperature is high may coincide with a time when the heat production is low. The inference from this is very important—namely, that the height of the temperature in fever is in great measure dependent on the momentary relation of the two processes of heat production and heat loss. And inasmuch as these two processes tend to vary irregularly, with but a weak *nisus* towards a daily rhythm, the fluctuations of the temperature do not afford an accurate measure of the changes in either process. The daily and hourly variations in febrile temperature are wider and more irregular than those in health: febrile temperature is *inconstant*. Moreover, trifling changes in the surroundings of the patient or in his functions readily send his temperature up or down: febrile temperature is *unstable*. The two coöperant factors of the temperature are acting more or less independently: thermotaxis is enfeebled or overpowered.

Dr. Hilton Fagge (whose name I mention with sincere and affectionate respect) has in his classical treatise on Medicine befriended, or rather perhaps adopted, a suggestion of Liebermeister's which requires some comment in this connexion. The wide acceptance among English students which any theory so endorsed is sure to gain makes me anxious that it should not pass without some critical examination. Liebermeister takes up the position that "pyrexia consists, not in a mere rise of the temperature of the body, still less in increase of heat generation, or in diminution of loss of heat, but in a change in the normal function of heat regulation by which the production of heat and its loss are so balanced as to create and maintain, while the pyrexia lasts, a higher temperature instead of the normal temperature. One might imagine the index of the regulating machinery to be shifted upwards, so that it is 'set,' not at 98·4°, but at 101°, 102°, 103°, or even at a still higher point."

The first objection I have to raise is that, if regulation means anything, it means, as I have already indicated, not merely an average uniformity of temperature persisting for any short period of time. Such a uniformity only implies that for a time the average losses of heat by all channels balance the average gains from all sources. So far as we know, it may be a fortuitous equation between two independently varying quantities. Regulation implies more than this—very much more. It implies *stability*; it implies such an intimate correlation of the producing process to the discharging process that their variations are not independent, but connected and concurrent; it implies a *nisus* towards a normal which is potent to overcome disturbing causes. We may know that a system of forces is in *equilibrium* when they keep a body at rest, but this rest is no evidence that the equilibrium is *stable*. To determine that we must disturb the body and note its behaviour. If it always returns to rest again, it has not merely equilibrium, it has stability. But, as I have just said, febrile temperature, even when it is at its height and oscillating with fair steadiness about a mean level, is marked by its instability. A trifle that in health would have but a vanishing effect will in fever produce a large and enduring variation. A whiff of cold air, a little food, a passing excitement, a feeble muscular effort, will send up or send down the temperature. The thermostatic character of the healthy normal is conspicuously absent in the mean high level of fever. The imperfect daily rhythm of temperature observed in some continued fevers is no evidence of true regulation. We have seen that even the fluctuating heat production of a fevered animal showed signs of a periodicity. In health this rhythm is deep-seated, and singularly persistent in spite of the most various disturbances. That it should to some extent 'show through' the irregularities of the fever heat is not wonderful: it merely proves that not all the thermal processes are utterly perverted in pyrexia; some that are normally rhythmic may be rhythmic still. But regulation has to do with balancing the integral sum of all the processes, and it is that balance which is overthrown, or at least rendered tottering, in fever. Liebermeister would seem, in fact, to have for the moment fixed his attention too closely on the characters of the *temperature curve* during the *fastigium* of some particular fever; and to explain its apparent average constancy threw out a sugges-

Digitized by Google

tion which has fascinated others more than himself. The cases given in support of his view are, I think, special, and admit of other interpretations. And he has admitted that its application to clinical and pathological facts must be limited and qualified. Dr. Hilton Fagge puts it forward as sufficient for all purposes, with an absoluteness which Liebermeister himself would hardly admit. According to Dr. Fagge, in fever nothing is changed; the norm of temperature is merely re-set. As Cohnheim puts it, the thermal mechanism of the man is of a sudden transformed into that of a bird. How is the transformation effected?—by what agents, acting on what mechanism? What determines the new fixed point of regulation? Is it fixed at all, or only sliding? How is it ever re-fixed? All these questions follow on the back of Liebermeister's explanation, and the worst of them is that they are not merely unanswered but unanswerable. One cannot conceive a physical or physiological method by which they might be attacked. This, as I understand, is what Cohnheim means when he says the theory has "ein gewisser mystischer Beigeschmack," and, in spite of Dr. Fagge's gentle protest, I confess I think the epithet not unjust.

The risk of laying too much stress on the high temperature of the body, and of regarding it *per se* as an index of the heat production, is, I think, further exemplified in a recent address by Dr. Ord to the Medical Society (Oct. 1885). Let me remind you of his words; they are admirably chosen and state the formal difficulty with great force: "The increased heat of the body in fever is to me a very constant stimulant of thought. When I ask people how it comes about, I am generally told that it is simply a matter of increase of combustion; that the oxidation processes of the body go on with undue vigour in fever; that the system is burning its candle at both ends, and that the two flames give more heat than one. When one looks at a patient who has passed through a febrile illness, one is ready to accept the explanation. He may have had no wasting discharge, hæmorrhage, or other obvious drain, yet there he lies, bloodless and emaciated to a degree which leads one readily to believe that on his bed of fever he has been consumed in all his tissues by an unseen fire.....But for some years my acceptance of this ready and most plausible way of accounting for the phenomenon has been hindered by an attentive consideration of an article on the 'Process of Fever,' contributed by Dr. Burdon Sanderson to the Reports of the Medical Officer of the Privy Council for the year 1875. The article contains an exhaustive notice of the best observations made up to that time with reference to heat production in the body during pyrexia..... I refrain from recapitulating the complex and very refined data upon which Dr. Burdon Sanderson sums up impressively. Suffice it to say that, after careful analysis of this data, he writes thus: 'The general conclusion to which the preceding calculation leads us is a very important one—namely, that although as compared with the heat production of a normal individual on fever diet the heat production of a fevered person is excessive, it is not by any means greater than the heat production of health.' There is in fever, it must be admitted, increased exhalation of carbonic acid and increased excretion of urea, *but after calculation they do not represent a source of heat sufficient to cause the increased temperature of the body.* I have read the article again and again, I have referred to various authorities on the subject, and I am compelled to say that the increased combustion explanation which satisfied me before has no longer the same value. To what, then, as I felt obliged to lose faith in my first belief, should I turn? Might, as some have argued, the increase of heat in the body be brought about by retention, by some state of the surface which would prevent the liberation of heat from the body and lead to accumulation within? The well-conducted observations of Leyden and Liebermeister tend to show that, far from being retained, heat is discharged from the surface in larger quantities in fever than in health. And we all know that intense hyperpyrexia constantly coexists with profuse sweating, involving the freest discharge of heat from the surface of the body, as in severe cases of acute rheumatism. If we are bound to deny the cogency of the two explanations, we are compelled to find a new one." Dr. Ord then goes on to suggest what I may call a new *vera causa*—that is, a possible cooperant cause for the liberation of heat in fever,—about which I shall have something to say later on. My object in making this long quotation has been to show that, while he fully appreciates and admirably states the experimental facts concerning fever which I have already touched on in this lecture (the failure of the retention theory, the increased discharge of heat, the increased production therein inevitably implied—nay more, the indefeasible evidence of increased "combustion" furnished by the increased products of combustion—namely, carbonic acid and urea), he is stumbled by finding that they "do not represent a source of heat sufficient to cause the increased temperature of the body." I venture to suggest that the difficulty is an unreal one. Dr. Burdon Sanderson everywhere distinguishes most carefully between thermogenesis and temperature. He even says there is "the strongest possible evidence that increased or diminished temperature has no necessary connexion with increased or diminished production of heat." "A source of heat sufficient to cause the increased temperature of the body" would be a phrase which Dr. Burdon Sanderson would hardly recognise as his own; and if we give it the meaning it was probably intended to convey—that the increased production of heat in fever is not accounted for by the increased combustion of the tissues as evidenced by the excreted matters—I can only say that I find nothing in the paper referred to that supports such a statement, and I do not know of any measurements which suggest it. There is high temperature in fever, and there is increased production, but the one is not the measure of the other. There is increased heat production in fever as compared with the heat production of health *on the same diet*, but not necessarily as compared with that *on full diet*. Somewhere between these two propositions comes Dr. Ord's, and I am afraid that between them it comes to the ground. I shall be glad if a re-examination of the premisses convinces him that he need not lose faith in his first belief. Dr. Sanderson's memoir, taken in conjunction with Professor Wood's, which supplements and corrects it, when properly weighed, will show him that his first belief is true, though perhaps not the whole truth. And as a final satisfaction I may add that, even though the preamble of his address is unproved, though the discontent with the existing theory which acted as a stimulus to his research was not well founded, the happy suggestion to which it led him appears to me to be true notwithstanding, in a certain guarded and limited sense.

Let me now recur to the outcome of Dr. Burdon Sanderson's analysis above referred to, because in speaking of the experimental evidence of increased heat production in fever I made no allusion to his results. On the surface they appear to tell against that evidence, but properly considered they are not inconsistent with it. When we say that more heat is produced by a patient in fever than by a patient in health, we must add the proviso—*in like circumstances*. One of the most important of these circumstances is diet. I being in health can, by eating to excess, raise my rate of heat discharge far above my usual rate, and I can lower the rate by fasting and still remain in health. If I become fevered I eat less and less, but my rate of heat discharge does not fall accordingly. In the report already mentioned, Dr. Sanderson, from the data before him, finds that the heat production of a fevered patient might be about 50 per cent. higher than in the same patient in health on a low diet. And if that is the case, some "increased combustion explanation" is not only satisfying but inevitable. Admitting increased heat discharge, increased exhalation of carbonic acid, increased excretion of urea, we must admit a source whence they are derived. They cannot come from the food consumed, for that is notably reduced in quantity; they can only come from the body substance itself; there *must* be increased combustion—the tissues *must* be "consumed by an unseen fire." But, to go further, there are not wanting grounds for believing that fever heat is often greater than normal heat even on a full diet. The Philadelphia experiments, made since Dr. Sanderson's paper was written, enable us to follow the thermal history of an animal for several successive days under varying conditions of diet and in varying degrees of pyrexia. The outcome is that in dogs and rabbits at least the fundamental part of the febrile process is an increase in heat production "by chemical movements in the accumulated material of the organism." And though, to use Professor Wood's expression, this increase was usually insufficient "to overplus the loss of production from abstinence from food," in some cases it was more than sufficient. Moreover, reasons are given—valid reasons, as I think—for surmising that what is occasional in the lower animals is probably common in man, in whom febrile movement is more pronounced and severe. In other words, it is

Digitized by Google

probable that in the fevered man there is sometimes an absolute, and not merely a relative, increase of heat production.

Allow me, in conclusion, to suggest an image; it is not perfect; it is far from being an argument; it is only an illustration of one aspect of the question before us. Some of us, in travelling by railway or by steamer, have been startled by the sudden stoppage of the engine. On inquiry we are told that the "bearings have heated," and we have perforce to be patient till they are cooled down. The normal temperature of the engine is dependent on the consumption of the fuel in its furnace, and when it is in good order its parts work together with but little wear and tear. But from unequal stress, or excessive speed, or defective lubrication, the friction at some bearing point increases, and soon the bearing becomes an abnormal source of heat, useless to the engine as a motive power and fraught with danger to its structure, for it means increased wear of the working parts, deterioration of their temper and their strength, and, as the heat mounts high, actual consumption and oxidation of their substance. The hot bearing is in a state of fever, its heat is wasted, and it is wasting. The warmth, the carbonic acid, the urea of health are evidence of so much food-fuel usefully transformed; the excessive heat and the excessive waste products of fever are evidence that the fabric itself is being wastefully consumed.

Lectures
ON THE
SURGICAL TREATMENT OF PULMONARY CAVITIES.

Delivered at the Consumption Hospital, Brompton,

BY RICKMAN J. GODLEE, M.S., F.R.C.S.,
SURGEON TO THE HOSPITAL AND TO UNIVERSITY COLLEGE HOSPITAL.

LECTURE I.

(*Concluded from page 459.*)

I NOW propose to give in some little detail the notes of some of the cases of pulmonary abscess which I have treated, and thus endeavour to illustrate the chief facts with regard to the various classes, only premising that, as in many other thoracic complaints where recovery takes place, a certain amount of uncertainty may occasionally remain as to the diagnosis; but before taking up the subject of gangrenous cavities I must refer to a very interesting paper by Dr. Coupland,[1] the text for which was a case of gangrene of the lung, following the bursting of a suppurating lymphatic gland situated near the bifurcation of the trachea. Surgeons are well acquainted with the condition of lung which was thus set up; it often follows cut throat or such operations as excision of the jaw or amputation of the tongue, where, if proper care be not taken, the discharges are highly septic and expectoration is difficult; it is one in which patches of pneumonia, started by the presence of putrid pus in the bronchi, are by the same cause converted into fetid gangrenous cavities. It is a condition of things which, as was pointed out by the late Dr. Pearson Irvine, often follows the pressure of an aneurysm or other tumour upon a bronchus, for a precisely similar reason. In the case in question an attempt to reach what was hoped to be the main gangrenous patch, but turned out to be only one of many, led to the setting up of pneumothorax and pleurisy, and hastened the inevitable end. Dr. Coupland's paper is important not only for his suggestions as to treatment, but also for some very interesting statistics gathered from the post-mortem records of the Middlesex Hospital. He tabulates a considerable number of cases, showing that by far the larger number follow croupous pneumonia, whilst many result from such causes as those to which reference has just been made. He also adds an account of the relative proportion in which the different lobes of the two lungs are affected, showing how frequently the upper lobe of the right lung suffers as compared with that of the left—a point to which I shall again refer in some remarks on the anatomy of the bronchi, which are to follow in the next lecture. The state of the pleura was also ascertained. There were adhesions in only a small proportion of the acute cases, and though they were present in all the chronic ones they were not always conterminous with the gangrene. In some acute cases there was more or less abundant lymph, in a few empyema, and in a few hardly any pleurisy. I will also abstract from Dr. Coupland's paper, as briefly as possible, the notes of some of the recent, but now classical, cases which have been published.

1. A boy aged seventeen swallowed a bone in November, 1883. He developed bronchiectasis, but completely recovered after coughing up the bone in February, 1884. This, I think, is most instructive, not only as showing that the bronchiectasis and induration of the lung, which had taken four months to develop, could be completely recovered from, but as indicating the line of treatment in such cases—a fact I will return to in the next lecture.

2. Dr. Magrath's case,[2] where a piece of grass became impacted in the right lung of a boy aged seven. Death occurred after ten weeks. The lower lobe of the lung was riddled with abscesses. The diaphragm (as in one of my cases) had been perforated by the abscess, and there was secondary caries of the spine.

3. Dr. Cayley's case,[3] which was one of a low form of pneumonia, resulting in a basic cavity containing five or six ounces of offensive pus and sloughs of lung substance. He had only been ill for five weeks, but had the appearance of a man in the last stage of phthisis. The cavity was opened in the ninth interspace, but the case ended fatally, being already too far advanced. There were signs of old tubercular mischief in the lungs.

4. Dr. Solomon Smith of Halifax records a case[4] where gangrene followed acute pneumonia, and where death followed an incision into the abscess after nine days.

5. Dr. Cayley's case of a gangrenous abscess following ear disease,[5] in which Mr. Gould punctured the abscess with a trocar, but on introducing the tube failed to drain the cavity at first; it afterwards, however, burst into the artificial opening, and the patient made a good recovery.

6. Some cases are recorded in a paper by Dr. Mosler, read before the German Medical Congress at Wiesbaden in 1883, in which he recommends the incision of the lung with the actual cautery for the extraction of foreign bodies. I am not able strongly to endorse this advice (though with deep incisions it may possibly be advisable), for the use of the knife does not, as a rule, lead to formidable hæmorrhage, and the charring of the tissues must cause considerable difficulty in any exploration with the finger.

7. Dr. Ed. Bull of Christiania[6] records a case of circumscribed gangrene of the lung, which was opened successfully.

It may be taken for granted, then, that the majority of the cases of gangrenous abscess which come into the hands of the surgeon are the result of acute pneumonia, and are situated near the base of the lung; and it may be added that his aid is most likely to be needed in those cases in which the gangrene is not very extensive, so that the patient survives the immediate effects of this process. Some of these cases, it is well known, recover spontaneously, the pus being expectorated; but in others a condition of things results such as is often met with in abscesses bursting spontaneously in other parts of the body—namely, that the opening being insufficient, and perhaps unsuitably placed, the sac is always more or less filled with the discharges, which in the cases we are considering are always highly septic, and therefore irritating. The abscess, consequently, shows no tendency to close, but, on the contrary, increases in size. It is not a good plan in such cases to wait long before making the external opening—that is, if the position of the abscess can be accurately determined,—because, as was pointed out when the subject of empyema bursting into the lung was discussed,[7] and as will be still further illustrated when the subject of bronchiectasis is before us, the presence of fetid pus in the bronchi and trachea is very likely to lead not only to serious consequences in the diseased lung, but also in the sound one: but, at the same time, it is not often

wise to make an incision through the chest-wall until the situation of the abscess has been ascertained by means of an exploring trocar, and even then the troublesome question of the presence or absence of pleural adhesions has to be settled before the lung itself is incised.

That one may be misled by apparently the clearest physical signs of the presence of a cavity is illustrated by a case that I saw with Dr. Douglas Powell and Mr. Horace S. Howell. It was that of a gentleman aged about thirty-five, who had marked physical signs of a small cavity about the fourth right interspace in front, the rest of the lungs being apparently almost if not quite healthy. The condition had lasted several months, and there was at times a copious fetid expectoration, at times very little of any kind. He was fairly nourished, but had some clubbing of the fingers, and was on the whole rather losing ground. A trocar was inserted (in July of last year), but no pus was met with. The signs, however, seemed so unequivocal that an incision was made through the chest wall, and, as strong pleural adhesions were found, the lung was incised and the incision enlarged with dressing forceps and the finger; but the abscess, which I cannot doubt was in close proximity to the seat of operation, was missed. Rather free hæmorrhage and some hæmoptysis occurred, which did not, however, give any trouble, and a drainage-tube was inserted in the hope that the abscess might burst into the track thus made, as happened in one of Dr. Cayley's cases mentioned above. This was unfortunately not the case here. The wound healed without any trouble, but the patient remained *in statu quo;* at least he continued when last heard of to expectorate pus from time to time. The general health certainly improved, and the expectoration became less fetid, but I doubt whether these results can be attributed to the operation. Clearly from this case a lesson is to be learned, for if a more careful search had been made with the trocar or aspirator it is more than likely that at last the pus would have been met with, and then the cannula would have served as a certain guide to the abscess; but an incision having been once made into the lung, it is easy to understand that the finger might push the abscess (perhaps a thick-walled one) to one side or the other, and thus render the chance of opening it a very remote one. If, however, the pus had not been met with, the patient would have been no worse off for the punctures, and the surgeon would have been saved the mortification of an unsuccessful operation. Another practical point is illustrated by this case, which I have seen exemplified in several others. The hæmoptysis followed the impinging of the trocar upon some firm substance, and then slipping into an apparent cavity. No doubt it passed through some pretty large pulmonary vessel, either just before or just after the puncture of the bronchus. Until the bronchus was perforated, any bleeding from this cause must have been external, and therefore easily controllable by pressure or plugging. The deduction is that, if such an obstruction is met with, the trocar should either be made, if possible, to work round it, or a puncture should be made in a fresh position; for although the hæmorrhage itself is not likely to be formidable from so small a puncture, it may be a very dangerous thing to have a patient who is under the influence of an anæsthetic coughing up blood, perhaps in rather considerable quantities. It should be added that the wall of a gangrenous or bronchiectatic abscess would not give this sense of resistance.

Whether this was really a gangrenous abscess or a bronchiectasis I am unable to say; but it illustrates well the point I am insisting upon—namely, the unwisdom of incising the lung until the presence of pus is ascertained. The following case might have led to a similar result if we had not been successful in puncturing exactly in the right place. It was that of a man at University College Hospital, aged forty-two, who was admitted in May, 1884, under the care of my colleague, Dr. Bastian. He was no doubt a tubercular subject, one of the very hairy tubercular people. His mother had died of phthisis when he was three years old, but there were no other cases of this disease in the family. He had, however, himself twice suffered from hæmoptysis sixteen and twelve years previously, and had had right pleurisy six years before, with which he was laid up nine weeks. Beyond these illnesses, however, he seems to have enjoyed good health, though he was liable to take cold easily after the last attack. The present illness began with a violent cough in Feb. 1886, which lasted up to the time of his admission on May 2nd, and was accompanied by hæmoptysis, night sweats, and wasting. He was found to have very few physical signs on the left side; but the right side, which was larger than the left and very motionless, was very dull at the lower part, and not very resonant above. The breath sounds and vocal fremitus were deficient at the lower part. On May 5th Dr. Bastian drew off one ounce and a half of bloody fluid mixed with pus, through a puncture in the eighth interspace behind, and this was followed by a marked reduction of the patient's temperature. On May 16th I ascertained with a needle the presence of the pus, but also that the collection was a very small one, for the first puncture, which was made a very short distance to one side of that made a few days before, did not strike the cavity; and on cutting down on the lung, after removing a piece of the eighth rib and ascertaining the presence of pleural adhesions, it was found that if the puncture were not made exactly in the original spot the cavity would be missed altogether. It was found, indeed, to be clearly in pulmonary tissue, and was just large enough to admit the finger and two and a half inches long, leading directly inwards from the external opening. This is an example of a lucky puncture in the first instance, for there were no sufficiently distinctive physical signs to indicate the precise position of the abscess; and it shows that in doubtful or suspicious cases several punctures at different points should be made before the search is abandoned. The man's cough was very much relieved for a time, the daily amount of expectoration sinking from one or two ounces to as many drachms, although the discharge from the wound was quite trifling; thus affording an illustration of a point that has been observed by several physicians—viz., that the amount of expectoration is no criterion of the size of the cavity, each pellet of pus, as it makes its way over the bronchi, setting up irritation and causing a great secretion of usually watery mucus; thus, a cavity not holding more than a couple of ounces may cause a pint of expectoration in the day. The patient improved very much for a time, but then he caught a fresh cold, and his cough and expectoration became more troublesome. He also had hæmoptysis whilst he was endeavouring to recruit at Eastbourne. In August he was readmitted, with the wound quite healed; but still a great deal of dulness, with weak breath sounds and no vocal fremitus at the right base, while at the upper part of the right lung there were tubular percussion note and bronchial breathing. This side of the chest was still almost motionless, but, instead of being larger, it was now considerably retracted. He was very weak, and had no doubt tubercular changes in this lung, to which many months afterwards he succumbed.

The enormous amount of expectoration which may result from the presence of a very small cavity was well shown in the case of a patient who formed the subject of a paper read by Dr. C. T. Williams and myself at the Medical and Chirurgical Society, and reported in the last volume of their Transactions.[8] I will merely mention here that a small basic cavity, not holding more than about one ounce, in a patient sixty-seven years of age, had given rise to the expectoration of more than a pint in the day for many months, and that the free incision of this cavity led not only to the complete stoppage of this troublesome condition, but was followed by sound healing in rather more than six weeks.

I will conclude this branch of the subject by the account of two cases, one of which is a typical example, and the other an illustration of the doubts occasionally surrounding the diagnosis of these basic cavities.

The first is that of a delicate girl nineteen years of age, who was admitted into University College Hospital, under the care of Dr. Bastian, on Jan. 5th, 1886, complaining of a troublesome cough and abundant fetid expectoration. She had suffered from typhoid fever in September, 1885, from which she had recovered slowly, and had only returned to her work a fortnight before the commencement of the present illness. Her parents were alive and healthy; a paternal aunt had died of consumption, and three of her five brothers had suffered from abscesses. Her illness began four weeks before her admission, in the early part of December, 1885, with an attack of headache, vomiting, and diarrhœa. She had to give up work, and continued ill, but with no fresh symptom, until the night of Dec. 31st, when she awoke coughing, and expectorated about a pint of similar fetid material to that which she had continued to bring up in larger or smaller quantities up to the time of coming to the hospital.

Ever after the first attack of vomiting she had felt a dull aching pain on the left side, which was not altered by coughing or vomiting, so I presume that the symptoms of the acute attack were the expression of the onset of a pneumonia, which led to gangrene of the lung. On admission she was thin, flushed, and short of breath, with a weak, husky, whispering voice, breathing at the rate of 32 per minute, with a paroxysmal, distressing cough, resulting in the daily expectoration of a pint or more of highly offensive, thin, watery pus and mucus. The pain was slight, but occasionally stabbing in the region below the left breast. The temperature was about 100°; the pulse about 130. The heart's apex was not far from the normal position—fourth interspace, one inch inside the nipple. The whole chest moved badly, the left side hardly at all. The percussion note was good, except on the left side below the eighth dorsal spine, where there was dulness and almost complete absence of breath and voice sounds, and usually there were no adventitious sounds. We had therefore but very little to guide us to the exact position of the cavity. Dr. Bastian punctured the chest in the eighth space an inch behind the posterior axillary fold, and in the ninth space an inch further forward, without result. On Jan. 16th we heard moist sounds at the base of the lung and bronchial breathing in the left axilla. Guided by the greatest intensity of these signs, I passed an exploring trocar into the chest in the posterior axillary fold in the eighth interspace, and hit the cavity after introducing the instrument about two and a half or three inches. An incision was then made down upon the intercostal space, and, the pleura being found obliterated by adhesion, the track of the cannula was opened up by sinus forceps, and a large cavity was reached in the lung, from which about twelve ounces of fetid pus escaped. I did not remove a piece of the rib in this case, as the pus was very offensive; thus, though a large drainage-tube could be introduced into the cavity, a complete exploration was impossible. The finger passed, however, through condensed but broken-down lung tissue, but reached only the outer part of an irregular cavity. The tube, though four inches long, no doubt only entered the outer part of this space, but air was sucked in and out with the peculiar whiffing sound which is characteristic, I think, of cases where there is a free communication with a bronchus—that is, as opposed to cases of empyema. The expectoration at once ceased, but though the temperature on the second day fell to normal, it rose again and remained at about 100° to 101° for a fortnight, when it rose to 103°. She then coughed up a pint of offensive pus, and the dressing, which for some time had been almost dry, was soaked with a similar material. This no doubt meant that the walls of the cavity had fallen together after the first evacuation, and both its exits had become closed. The gradual accumulation of pus in the slack cavity kept up the temperature, and the sudden fit of coughing opened both of the exits again. Had I been able at first to introduce a still longer tube, no doubt this would not have happened. It is a good illustration of a common source of trouble in cases of this kind, and shows that a much longer tube is usually required than in cases of empyema. The temperature now kept about 99° to 100° for another fortnight, and we thought we might remove the smaller but longer tube which had been substituted for the original large one; but it was too soon, for the temperature went up again, reaching almost 104°, and necessitating the dilatation of the sinus and the reintroduction of the tube. After this the temperature remained for a few days about 100°, and then became peaky, ranging usually from 99° or 100° to 101°, but twice reaching 102°. There was in the meantime but slight discharge and occasional slight expectoration, and so I have no doubt that, all this while, there was not a complete drainage of the cavity. Ultimately she went to Eastbourne on March 25th, about nine weeks after the operation, still wearing the tube; and a month later returned, with nothing to show except a retracted chest with some curvature of the spine and deficient resonance and weak breath sounds over the affected part. The tube was now withdrawn, and in a week the wound was healed. The patient has since remained well.

The second, a somewhat similar case, one which illustrates the same difficulties in treatment, I saw with Dr. Broadbent and Dr. F. Russell in May, 1884. The patient, an unmarried woman aged forty-four, was seized with the symptoms of pleuro-pneumonia on the right side on May 26th. The pain in the side and back continued till June 11th at midnight, when she expectorated a large quantity of offensive pus. The expectoration, which was accompanied by high fever and purging, continued till June 19th, when I saw her. She had then a patch of dulness as large as the palm of the hand in the right front, reaching up to the nipple and down to the liver dulness. Over this area there was some puffiness and tenderness, and tubular respiration was to be heard. The rest of the chest was resonant, but loud mucous râles were everywhere audible, and the lungs were evidently becoming completely choked up. The patient was in great misery, the cough being most distressing, and apparently she had not long to live. An opening was made in the seventh interspace, immediately below the nipple, and the finger passed readily into a cavity, from which a large quantity of offensive pus escaped. It felt rough and irregular, and seemed to be an excavation in the lung itself; it certainly was not the general pleural cavity, but might of course have been a localised diaphragmatic empyema with much lymph on the walls of it. A tube three inches long was introduced, and the wound was dressed with oakum. The result of evacuating this cavity was very instructive, for not only did the expectoration at once cease, but the rest of the lungs promptly recovered, so that in a day or two all the râles had gone. The temperature fell almost or quite to normal, and the diarrhœa stopped. Unfortunately, about July 1st, the tube, none too long to begin with, was shortened without my knowledge by fully an inch; and this was followed by the same train of symptoms as occurred in the last case, when the accumulation took place in the abscess—viz., malaise, nausea, fever, and at last the expectoration of fetid pus. The sinus was dilated with bougies and a long tube (five inches) was introduced; but we did not at once obtain complete drainage, and a certain amount of pus was still expectorated, though a good quantity came through and alongside the tube. The temperature in the meantime came down to normal, and the patient experienced great relief from a suggestion of Dr. Broadbent's that she should lie upon the face, thus encouraging the escape of the pus through the wound and so diminishing the cough. The cough and other troublesome symptoms gradually disappeared; the tube by July 25th had been reduced to three inches, and the patient was convalescent and had left her bed, when she felt a sharp pain at the right hypochondrium, which soon passed off. Next morning, however, pus appeared in the motions, probably from a diverticulum of the abscess, which the tube had never drained efficiently, and this continued, though gradually diminishing, for about three weeks. The tube slipped out on July 29th and was not replaced, and from this time the patient made an excellent recovery, a little dulness and weakness of breath sounds round the affected area and a slight drawing up of the liver being all that remained from the attack.

This rupture of a pulmonary abscess into the colon seemed to me an almost inexplicable occurrence; but in January of this year I made a necropsy on a case of liver abscess bursting into the pleura, which opened my eyes as to the manner in which a diaphragmatic empyema, or an abscess even in the anterior part of the lower lobe of the right lung, may discharge itself in this way. It may pass down behind the posterior part of the pleura, keeping rather to the right and perforate the attachment of the diaphragm about the tenth rib at the posterior fold of the axilla, when it will be quite close to the hepatic flexure of the colon.

In both these cases there are the same lessons to be learned. First, if it be suspected that the cavity be in gangrenous lung it should be well opened up and explored by the finger, and a good long tube should be put in. Secondly, the tube must be kept in until the discharge has almost, and the expectoration quite, ceased, while the temperature remains low, for the cavity is probably an intricate one, and it is not unlikely that the walls will have to throw off sloughs, and cannot, therefore, immediately assume the healthy condition which is met with in the case of most empyemata. They both illustrate the complete recovery, as regards physical signs at all events, which may be anticipated in such cases.

AYRSHIRE MEDICAL CLUB.—At the annual meeting of this club, held on the 4th inst., Dr. Robertson, of Ardrossan, was elected President; Dr. Dobie, of Ayr, Vice-President; and Dr. Moore, Secretary. The membership now numbers fifty-three.

ABSTRACT OF

Lectures

ON THE

ACTION OF NERVE CENTRES AND MODES OF GROWTH.

Delivered at the Royal College of Surgeons, February, 1887,

BY FRANCIS WARNER, M.D., F.R.C.S.,

HUNTERIAN PROFESSOR OF COMPARATIVE ANATOMY AND PHYSIOLOGY AT THE COLLEGE.

LECTURE I.

ON THE ACTION OF NERVE CENTRES.

MOVEMENTS are here studied as signs of action, observations being recorded by verbal description, or by the graphic method.[1] To study a movement involves the consideration of the part moved, the muscles moving it, and the nerve centres which stimulate them, while the movement itself indicates the time and quantity of action in the nerve centre corresponding; these are called the intrinsic attributes of the movement. The *time* of a movement often affects its outcome or sequence; movement of a single part is a comparatively simple fact; when several parts are acting, combinations of their movements occur. The special combinations of movements are simply the result of the time of the action of each of the moving parts. In observing movements of the digits two modes of description may be employed: the series of movements of each digit may be described, or the series of coincidences or combinations of acts may be recorded. Either plan may be used, as convenience may dictate; thus, it may be said that each of the five digits flexed at the same moment, or it may be said that the hand assumed "the convulsive posture." What we commonly call an action, such as writing or walking, is really an observed series of combinations of movements; this applies equally to spontaneous, reflex, or voluntary actions. When a child seizes an orange we observe a series of movements, each of which can be performed separately, while the character of the action depends upon the time and quantity of each of the component movements. Series of movements in plants were then described. The *quantity* of a movement is its second intrinsic attribute; it indicates the quantity of action in the nerve centre. Quantities of motor action are studied in observing postures of the body as signs of the ratios of force in the nerve centres. In "the straight extended hand"[2] we observe a sign of the temporary equilibrium of the nerve-muscular apparatus for flexion and extension. The posture may change, the fist being clenched; the change of hand posture is a sign of a change in the ratio of force acting in the apparatus for flexion and extension, the force of flexion being increased. Thus we see the outcome of the balance or ratio of quantities of motor force demonstrated by the observation of postures. Examples were given concerning other hand postures. It was argued that postures often indicate the condition of the nerve system, that they are often changed by the sight of objects, that they are due to the ratios of force exerted by opposing portions of nerve-muscular mechanism, and hence that postures are signs of ratios of action that can be controlled by incident forces, such as light, sound, mechanical irritation, &c. The total quantity of movement seen in man may depend upon the quantity of blood-supply, and upon the amount of stimulation of the subject; the blood-supply and stimulation are needed to produce movements. In anæmia and in starvation the quantity of movement is lessened. In darkness but little movement occurs in a well-nourished man; the sight of an object may be followed by the head turning towards it, and by other series of movements, such as result in the seizure of the object. The quantity of movements in plants is mainly determined by light and heat.

The proposition was then enunciated that every movement depends on some change in the time or the quantity of action in the nerve-muscular apparatus producing it, and that every such change in the apparatus must be preceded by some stimulus acting on it immediately antecedent or more remotely antecedent. Among the forces which, acting upon a man, may stimulate and control the individual movements, the following were mentioned and illustrated: light, heat, sound, mechanical irritation, &c. Every movement must have some sequence, whether it be to supply food or be expended as physical energy. The sequence of a movement must be carefully separated from the cause or antecedent. To say that the bee visits the flower to get honey is to imply that the honey causes the visits. It was argued that the bee sees the flower, and afterwards gets the honey; that it is not the honey, but the light reflected from the flower, which determines the movements of the bee. The forces which control the time and quantity of the acts composing a series of movements are really the antecedents of the results of the action. The sequences, outcome, or results of movements are often said to be useful, intelligent, voluntary, purposive, &c. What is meant by the outcome of an action being useful? What is the connotation of the term "useful" expressed in terms of physical criteria that can be observed? Concerning the meaning of the word "useful" as applied to the outcome of an action or movement, the primary idea seems to be that the outcome produces some physical change that can be observed. A movement which brings food to the subject is said to be useful partly because it produces some effect or impression on the subject. The movements of deglutition, respiration, and all the movements of organic life are useful because, among other things, they impress the subject considered. We do not say that all acts which produce an impression are useful, but to be useful there must be survival in the subject producing the act, or in others considered at the same time. It is insisted that usefulness is not an intrinsic character of any movement, but a relation of its outcome to surrounding objects.

Impressionability as a property in man may be indicated by movements. If the movements of a man are regulated and controlled by light or sound, he is impressionable to these forces. In coma impressionability is lost, but the eyes may move spontaneously and independently of one another; this is seen under chloroform, and in the deep sleep of infants. Actions may be defined as similar if on two or more occasions there be movements of the same parts of the body, the action of each part respectively being alike in time and in quantity on each occasion. In a body of soldiers at drill the movements of each man are similar. Thus actions, or series of movements in the same or in corresponding parts, are identified as similar on account of their intrinsic attributes. Similar movements may recur in a man, or be repeated; each such occurrence after the first is a repetition or reversion of the action. A trick or habit in a man may revert in his children. Similarity of actions is here defined as an observed fact, not as a question of relation to antecedents or sequents of the action.

Automatic or spontaneous movements are such as have no special antecedents controlling their attributes. Athetoid movements are automatic; they occur in similar series whenever any impression is made upon the subject. *Instinctive movements*, so called, probably imply a certain structure of the nerve system due to its inheritance—such that when stimulated by certain surrounding forces the movements resulting should be regulated by those forces, the sequence of such acts producing some impression upon the subject directly or indirectly. Purposive or intelligent movements are probably always controlled by forces surrounding the subject, or by impressions previously made; the sequences of such movements, rather than their antecedents, possess the characters of intelligence. It seems that the purposive or intelligent character of a series of movements is not due to its intrinsic attributes, but to its sequents. The respiratory movements are considered very automatic when occurring in regular and uniform order of time and quantity; but when the sight and sound of various objects modifies them, to form speech, laughter, &c., then they are signs of mental action. All expression of mind and mental states is by series of movements, and these of course have their intrinsic attributes, observable in the body. *Coördinated movements* are such series of acts as have special characters, dependent upon the time and quantity of the component movements. It is also an essential character that the attributes of the series are determinable by sight, sound, or other modes of force acting

upon the subject. Movements may be classed according to their results as respiratory, acts of deglutition, &c. For the purposes of a scientific classification of movements it is very desirable that they should always be described according to the parts moving, their intrinsic attributes, the antecedents and sequents, or outcomes. All these characters are capable of direct observation.

It has been said, What is the good of these studies of movements? What practical advantages are likely to result therefrom? Nerve-muscular movements are physical signs of brain action; with but few exceptions, they are the only signs of brain action, and the only physical signs by which we know anything of the action of mind. Describing facts in man as we see them, in terms of movement, is probably the best mode of attempting to do away with such metaphysical terms as "voluntary," "intelligent," "purposive," in scientific descriptions. Facts must be described in physical terms before we are likely to find out their physical causation.

LECTURE II.

THE STUDY OF MODES OF GROWTH.

In making a systematic study of movements in man, we study one function in one class of subjects. We observe the movements as signs of the time and quantity of action in the loci of nerve tissue which produce them; thus we learn much concerning vital action in one kind of tissue. If the methods and principles found useful in studying this one function in one tissue have been properly considered, they are likely to be useful in studying other functions in other living subjects. In studying movements we learnt to note the parts of the subject capable of acting separately. We learnt next to study the intrinsic attributes of each movement, and also its antecedents and sequents. Having studied the nerve-muscular apparatus of man as our special subject, and deduced certain principles therefrom, we proceed to apply these to the study of various problems. We shall find that many phenomena of growth are determined by the forces which control the time and quantity of growth in the units of living tissues. The study of movements requires the observation of a definite number of parts of the body and a definite number of loci of brain tissue; in growth the number of parts, or units, capable of separate action is practically indefinite. Movement is in many cases a reflex act; growth is, presumably, never spoken of as a reflex action. Movement often follows quickly upon an impression; if growth results, it is slow in its manifestation. Movements in man are often signs of intellectuality; acts of growth are never said to be signs of mind. The many beautiful adaptations of growth in plants are not considered signs of intelligence in the plant; but the movements of an insect in visiting the flower are considered signs of its instinct. The results of growth are material changes, and as such are permanent records of action, capable of preservation; movements do not necessarily leave any permanent record in the subject of such kind as can readily be seen and preserved. In speaking of movements as signs of action in nerve tissue and of growth, we deal with two functions in the body. The outcome of nutrition in the child will vary at different ages; in the early years much nutrition is consumed in making weight; in adult life much energy is consumed in movement. In a child becoming choreic the weight falls and movement increases. If we believe in one series of laws of nature governing movement and growth, we must expect the forces controlling movements to be those affecting growth.

We may observe the *time* of any movement, vital act, or act of growth; we commonly speak of relations in time as the order of growth; in describing the processes of development the order of development is most important. We more commonly study the time of movement than that of growth, because the processes of growth are slower, and observation must be continued for a longer period to see any change than is the case in observing movement. Visible movement indicates its own time to the observer, but does not necessarily leave any permanent record; growth is a process which usually does not impress the observer with the time of its acts, but leaves a result in visible form. A visible effect of movement in man is to produce some fresh posture, or condition of temporary equilibrium. With regard to observation of the effects of forces upon the subject, in the case of growth a much longer interval usually elapses between the stimulation of the subject and the sequential effect than that which takes place in a reflex movement. Hence more instances of growth are called "spontaneous" than in cases of movement. In flowers cross fertilisation often results from the fact that the anthers are, in certain cases, ripe before the pistil. The time of dentition, the time when hair grows upon the scalp, face, or pubes, are characters of the normal process.

The second intrinsic attribute of growth is its *quantity*. Many phenomena may be described, and receive some kind of explanation by noting the ratios of growth in the parts compared. To note the ratios of growth in a specimen is analogous to studying postures which are due to ratios of action in the nerve-muscular apparatus; this suggests the hypothesis that the forces which lead to certain postures in man may be those which control his growth. Illustrations were drawn from the modes of growth seen in the development of buds, and from comparison of wild and cultivated plants. The ratios which indicate growth in man are the subjects of anthropometry; ratios indicate the differences in growth of young and old leaves and in the parts of man at successive ages. Unequal proportional growth of bilateral parts is a common cause of curvatures; this is seen in the increasing curves of bones in the fœtus as development advances, and is abundantly illustrated in the stems of plants. In the two halves of the body and in the corresponding members the ratios of growth are usually equal, but the right arm is often larger than the left in girth—probably owing to the greater amount of stimulation it receives from the brain.

Among the forces producing certain ratios of growth we see that light increases the size of leaves, while it diminishes growth in internodes, and does not control the growth of flowers. Light diminishes growth in the side of the stem of a plant which is most illuminated, and curvature towards the light results. Mechanical pressure, heat, and electricity may to some extent control quantities of growth. Gravity in plants causes upward curvature of the stem and downward curvature of the root. If a circular hole be made in an iron plate, heat causes equal extension of the metal in all directions, and the hole is enlarged, but remains circular. For similar reasons, in the growth of bones in which uniform extension is taking place in all directions, the foramina enlarge, retaining their shape; this is seen to a certain extent in the foramina of the pelvis. In the skull of the infant the anterior fontanelle becomes larger in the early stages of growth. If in the processes of growth one tissue or one part grow in greater quantity than others, that tissue or part is said to be hypertrophied. The sequences of proportional growth are many. In a composite flower the increased growth which occurs in the style after the anthers have discharged their pollen is followed by cross fertilisation. The ratios of the growth of parts may bring about asymmetry of form, malformations, or variations in development, and consequently in the use of parts; examples are seen in descriptions of short-horned and long-horned cattle, and in the proportions of the beak of pigeons. Look at a germinating seed; it consists of an embryo enclosed in its testa or covering; germination begins by the swelling and growth of the embryo; but the testa does not grow, it may stretch a little, but soon the unequal increase in size of the embryo and seed case is followed by splitting of the testa.

We often speak of one subject growing similarly to another, or of the growth in two subjects being similar. It often happens that the similarity of growth is in part due to equal ratios of growth in the two; in this sense similarity of growth may occur in unlike subjects if the ratios of growth are equal in each. We found that movements in two men may be said to be similar when they occur in the corresponding parts of each, and are alike in their time and quantity. In like manner acts of growth are sometimes said to be similar when they occur in the corresponding parts of two or more subjects at the same time, and in the same quantity as in two pea-seeds grown under similar circumstances. Similarity of growth may be partial; in two subjects the growth may be similar as to time, or quantity, or kind. When two processes of growth are different in kind they may be similar in time; the growth of leaves and of underground tubers may occur at the same time, and this may be the only point of similarity between the two processes of growth.

In classifying facts concerning the processes of growth according to such intrinsic attributes as are observable, our object is to seek the causation of the attributes observed.

Digitized by Google

Having classed a number of facts as examples of unequal bilateral growth, we may seek to determine the causation of unequal bilateral growth. In pursuing such methods of inquiry we follow methods similar to those which aided us in studying the motor functions of the brain. Thus we have lines of thought to guide observation. It is possible, and indeed highly desirable, to arrange a museum in which specimens are classified according to the attributes of their growth, and the forces that stimulated their growth and produced that special ratio of their attributes. Probably this was in part the principle followed by John Hunter.

The rules that should be followed in making analogies were pointed out. It was shown that we can only compare things or acts as to the characters or attributes which they possess in common; we may compare like functions as to their time and quantity; it is only as to the time of action that we can compare unlike functions; we do not directly compare the material things, but the attributes of their functions. Growth in a child and in a plant were then compared, and other examples were put forward. In our desire to give some kind of explanation of facts in nature we use processes of analogy. Acceptance of the hypothesis of evolution encourages the study of analogies; our purpose in making analogies between processes of growth is to classify examples in the best manner for seeking their causation. The term "reversion" is used to imply that the outcome of growth observed is similar in its intrinsic attributes to others that have previously been observed. The reversion is a repetition or reappearance of vital acts similar in their intrinsic attributes, and occurring in similar subjects. The following proposition was enunciated as an epitome of the principles illustrated: "Every vital act, or act of growth, requires among its antecedents a supply of pabulum, and stimulation by some force incident to the subject."

PYREXIA AND HYPERPYREXIA.

BY T. J. MACLAGAN, M.D., M.R.C.P.,
PHYSICIAN IN ORDINARY TO THEIR ROYAL HIGHNESSES PRINCE AND PRINCESS CHRISTIAN OF SCHLESWIG HOLSTEIN.

(*Continued from page 467.*)

THESE clinical facts afford distinct evidence that injuries and non-inflammatory lesions of certain parts of the nervous centres cause a rise in the temperature of the body as great as that noted in inflammatory and febrile ailments. That such lesions give rise to such results shows as clearly as evidence can that the nervous system exercises a marked influence over the body heat. That all injuries of the nervous centres do not give rise to this result shows that this influence is not generally distributed, but is limited to particular parts of the nervous centres. To recognise this is to go a long way towards recognising the existence of a thermic centre. And on no other view than this can the facts which have been adduced be explained. The evidence in support of the doctrine of a thermic centre is indeed little, if at all, less potent than that on the strength of which we recognise a vaso-motor, a respiratory, a cardiac, and many other centres, whose existence we do not call in question. The chief difference is that the exact area of the thermic centre has not been so accurately defined, though sufficient evidence has been adduced to ead some observers to indicate its probable seat. 1

So far as our present inquiry is concerned—so far, that is, as concerns the theory of fever—the exact location of the thermic centre is not a matter of importance: the important thing is that we should recognise that the evidence all tends to show that there is such a centre exercising a direct and dominant influence over the body heat, and that rise of temperature may be directly due to disturbance affecting it. The acquisition of such knowledge could not fail to materially influence our views as to the causation of fever. If there exist a thermic centre, and if injuries affecting this are capable of causing a rise in the body heat, may not the preternatural heat of ordinary febrile ailments be also directly due to the disturbing action on this centre of the so-called fever poison? Such a question was bound to arise so soon as the full bearings of the facts, physiological and pathological, which have been related, were recognised. The necessary outcome of the recognition of a thermic centre was a "neurotic" theory of fever. And no time was lost in enunciating it; for in the same volume in which his experiments are related, Wood [1] starts this theory. "Granting," he says, "the existence of a fever centre in the nervous system, the laws of life teach us that there must be poisons capable of acting upon it directly, so as to produce fever. Such a fever would certainly be neurotic, although produced through the blood, the vital fluid acting simply as a common carrier. With this understanding of the terms, distinctly clear proof is at present wanting that the fever even of pyæmia, of the exanthemata, or of any so-called blood poisoning is strictly hæmic, since such toxic fever may be due to an action of the poison upon the central nervous system." This theory has been adopted and more fully advocated by Hale White, who believes that "in specific fevers, inflammations, traumatic and urethral fevers, the rise of temperature is due to peripheral stimulation of afferent nerves reflexly affecting the calorific centre." [2]

That there exists somewhere in the brain a centre controlling and regulating the production of animal heat, and that lesions affecting this may cause the temperature of the body to rise, is a proposition which, in the face of the facts related, can scarcely be called in question. It is a clinical fact, demonstrated by many independent observations, made during the last twenty years, that non-inflammatory lesions of certain parts of the nervous centres have for one of their symptoms a great and rapid rise of temperature. But, on the other hand, it is equally a clinical fact that the body heat is raised during maladies in which there is no suspicion of lesion of the nervous centres. So various are the maladies of which increased body heat is a symptom that it is *primâ facie* improbable that this increase should in all cases be brought about in the same way, and the more we consider the clinical facts daily brought under our notice the more apparent does it become that all fever-producing causes are not similar in their mode of action. And, independently of the clinical evidence, a consideration of the physiology of thermogenesis leads to the same conclusion.

The thermal apparatus consists of various parts, and is distributed over the whole body, more or less. First there is the thermal centre, situated in the brain, somewhere above the junction of the pons and medulla. Such a centre would be of no use, and could be no centre at all, without a connexion with the parts of the body in which heat is produced, for without this it could exercise no influence over heat production. It must equally be in direct communication with the parts of the body by which heat is eliminated, for without this it could exercise no control over heat elimination. A thermic centre could no more control and regulate the production and elimination of heat without a connexion with the seats of heat production and heat elimination than the vaso-motor centre could control the circulation through the minute arteries without being in communication with the muscular coats of these vessels. The only way in which such a connexion could be established is by means of nerves, for nerves are the sole media by which impressions are conveyed to and from nerve centres. The parts which go to form the thermal apparatus, therefore, are: 1. The tissues in which heat is formed. 2. The surface from which heat is eliminated. 3. A central controlling power in the brain. 4. Nerves connecting this with the heat-forming parts of the body. 5. Nerves connecting it with the heat-eliminating surface. The harmonious working of these different parts of the thermal apparatus gives rise to the phenomena of thermogenesis; and the general result is a persistent temperature of 98·4°. Interruption of this harmony causes the temperature to rise or fall. Fall of temperature is due either to lessened formation or increased elimination of heat. Rise of temperature is produced either by increased formation or decreased elimination. The latter cause (the hypothesis of Traube) we have already considered in its application to the explanation of the increased body heat of fever, and have seen reason to reject it as incompetent to explain that phenomenon. There remains for consideration only increased formation. Rise of temperature due to increased formation may be brought about in two ways: by direct stimulation of the processes by which heat is formed; or by diminished activity of that by which heat-formation is inhibited, or kept within due bounds.

Rise of temperature due to direct stimulation of the process by which heat is formed.—This process is the tissue metabolism. Rise of temperature thus produced must, therefore, be brought about by some agency which increases that metabolism. Heat is an excretory product, a result of

[1] P. 215. [2] Practitioner, Jan. 1868.

Digitized by Google

retrograde tissue change, and cannot be produced apart from that change. To say that heat could be directly brought about by stimulation of a heat-producing centre without increased tissue change would be to place heat as a product on the same level and in the same category as volition and emotion, which is absurd. No, increased heat due to direct stimulation of the heat-producing process must be due to the operation of some agency capable of causing greatly increased activity of tissue metabolism. But the most potent nervous influences of which we know, those which exercise the most powerfully stimulating influence over tissue metabolism and the nutritive processes which constitute it—happiness, change of scene, &c., —never do more than bring metabolism to the standard of health; they cause increased activity of the trophic influences which preside over metabolism, but they never raise the temperature above the normal. That the continuance of normal tissue metabolism is dependent on influences conveyed to the tissues by the trophic nerves is undoubted. But there is no evidence to show either that any influence so conveyed is capable of causing the temperature to rise above the normal standard, or that stimulation of any portion of the nervous centres is capable of causing such increased body heat as is noted in fever. Rise of temperature due to direct stimulation of heat-production must therefore result from the operation of some cause whose influence is exercised directly, not on the nervous system, but on the tissues in which heat is formed, the morbific action taking place, not in the nervous centres, but in the structure of the tissues. We can no more have increased formation of heat without increased activity of the processes during which heat is formed, than we can have increased formation of urea or increased formation of carbonic acid without increased activity of the processes during which they are formed. That is the combustion theory of fever—a theory which we shall by and by see fitly and accurately explains the rise of temperature in the most common and important febrile ailments with which the physician has to deal.

Meantime we are dealing with the influence of the nervous system. Though there is no evidence of the existence of a special centre for heat production, we nevertheless admit, and argue for, the existence of a thermic centre. If it has no influence in heat production, what is the function of this centre? All evidence tends to show that its function is essentially inhibitory, that it controls heat formation, and by its ever-constant action prevents it from passing due bounds, and so helps to keep the temperature at the normal standard. Inhibition restrains and regulates functional activity, as the reins restrain and regulate the pace of a spirited horse. Slacken the reins, and he hastens his pace; let them go, and he is off at the gallop. Inhibition is an active, not a passive, agency, and is in constant operation. This is well exemplified by the action of the vagus on the heart; stimulation of that nerve slows the heart's action, and, if the stimulus be strong enough, may arrest it altogether, the arrest taking place in diastole. But the nervous system which supplies this inhibiting force supplies also another, which, reaching the heart by another channel, has exactly the opposite effect; it stimulates the heart to increased activity. These two forces are in constant operation, and so counterbalance each other that the heart is normally kept beating at the rate of about 70 a minute.

Just as there is no organ whose normal amount of work represents the full measure of its capacity, so there is no function whose normal state of activity represents the full capacity of its performance; each is restrained and kept within physiological bounds by the inhibiting action of the nervous system. The heat-producing function of the body is no exception. Normally, heat production is counterbalanced by heat elimination; but that is only while heat production is kept within due bounds by the constant control of the heat-inhibiting centre. Let the rein be slackened, or heat inhibition impaired, and the temperature runs up several degrees, and pyrexia results: let the reins be cast loose, or heat inhibition paralysed, and heat production is freed from all restraint; it is off at the gallop, and hyperpyrexia results. That is the neurotic theory of fever.

These are the two theories of fever with which we have to deal: 1. The combustion theory, according to which the rise of temperature results from increased activity of the process by which heat is naturally formed in the tissues. 2. The neurotic theory, according to which the rise of temperature is due to impairment of that inhibitory force by which the heat-producing process is kept within normal non-febrile bounds. These two theories are not antagonistic. Each is complete in itself, and exists independently of the other. Each has its own special sphere of application.

There are maladies characterised by increased body heat in which the rise of temperature is best explained by the combustion theory. Others there are also having for one of their characteristics a rise of bodily temperature on which that theory throws no light; but of whose increased body heat the neurotic theory affords an adequate explanation. Here comes in that test of practical utility to which all theories should be subjected, and on the results of which should depend their acceptance or rejection. It will lead to a clearer understanding of the whole subject if we take the neurotic theory first.

The clearest and most undoubted cases of neurotic pyrexia are those in which the rise of temperature succeeds, and is symptomatic of, a non-inflammatory lesion of the nervous centres. Examples of such pyrexia we have in that which accompanies cerebral hæmorrhage, tumour of the brain, and injuries of the cervical cord. No other explanation can be given of the rise of temperature in these cases except that offered by the neurotic theory as here set forth. It is impossible to regard the results of such lesions, consisting as they essentially do of pressure upon or laceration of a portion of the nervous centres, as other than paralytic in nature. The effect of all such mechanical lesions is not to increase, but to impair or abolish, function—to produce more or less paralysis. The only way in which a destructive and non-inflammatory lesion could cause temperature to rise is by impairing that function which normally prevents it from rising—in other words, by impairing heat inhibition. Rise of temperature thus produced will vary according to the extent of the lesion; in slighter injuries there may be no serious damage to the heat-inhibiting centre, and no great interruption of the connexion between it and the heat-forming tissues, and consequently no greater rise of temperature than is noted in cases of cerebral hæmorrhage in which the sanguineous effusion is small and does not open into the ventricles. In more extensive lesions, in which the inhibiting centre is more seriously damaged, or the connexion between it and the heat-forming tissues more seriously interrupted (as in severe cases of cerebral hæmorrhage in which the effusion is more extensive and tears its way into the ventricles), the temperature rises rapidly and to a much higher point; while the highest temperature of all is noted in cases of crushing of the cord, in which the heat-forming parts of the body may have their connexion with the heat-inhibiting centre cut off more completely than is likely to be the case in any intracranial lesion.

Admitting the existence of a thermic centre, whose function it is to control heat formation and prevent undue rise of temperature, we have no difficulty, in the maladies and injuries to which reference has been made, in attributing the increased body heat to interference with that function. The temperature rises because the reins are slackened. The sequence of events seems to admit of no other explanation. Carrying out this line of argument, we cannot fail to see not only that the rise of temperature thus induced must be directly as the extent to which heat inhibition is impaired, but that paralysis of the thermic centre, by abolishing inhibition and leaving heat production in uncontrolled possession of the field, must lead to hyperpyrexia. And the more we consider the pathogenesis of febrile heat, the more apparent does it become that impairment of inhibition is a much more likely cause of hyperpyrexia than is direct stimulation of heat production. Heat inhibition remaining unimpaired, tissue metabolism could scarcely cause those very high temperatures which characterise some cases of hyperpyrexia. Heat inhibition being paralysed, there is no difficulty in seeing that the temperature cannot fail to rise, and to go on rising, so long as tissue metabolism and heat production continue.

All cases of hyperpyrexia we therefore regard as being probably of neurotic origin—as due to some cause which exercises a paralysing influence on the thermic centre. Pyrexia may result either from increased production or from defective inhibition, but marked hyperpyrexia is probably due only to defective inhibition. In the cases hitherto instanced there has been a direct lesion of the nervous centres to explain the paralysis of the thermic centre and the consequent rise of temperature. Other cases there are, however, in which the evidence of paralysis of that centre is equally marked, in which hyperpyrexia is pronounced

Digitized by Google

but in which the sequence of events by which it is brought about is not so apparent.

But mechanical lesions and organic disease are not the only causes of local paralysis. Paralytic symptoms, often not much less marked than those which follow organic lesions of the nervous centres, occur in hysteria; we recognise them, too, in connexion with gout, rheumatism, and disease of the kidney, and we constantly find them occur as a sequela of diphtheria. Excessive functional use may also lead to impairment and partial paralysis of a part, as in scriveners' palsy. *(To be continued.)*

A CASE OF RHEUMATIC HYPERPYREXIA.

BY FREDERICK TAYLOR, M.D., F.R.C.P.,
PHYSICIAN TO GUY'S HOSPITAL.

THE case of rheumatic hyperpyrexia read by Dr. Carrington at the last meeting of the Clinical Society (at which I was unable to be present) reminds me of one that occurred to me a few years ago, in which the difficulties of treatment in private practice had to be met, and were met successfully, though the patient was subsequently removed to the hospital that any relapse might be anticipated.

On October 5th, 1882, I was asked by Mr. F. G. Larkin, of Trinity-square, to see with him a patient living in the neighbourhood. He was a man aged forty, and had been suffering from rheumatic fever for a week, during which time the pains had not been very severe, and he had been treated with salicylic acid in doses of twenty grains every six hours. There was apparently nothing unusual in the case until midnight on Oct. 4th, when sweating, which had hitherto been profuse, ceased, the joints were no longer painful, and in the course of the next few hours he became delirious. At 7 A.M. on the 5th he was beginning to be drowsy, and his comatose condition rapidly developed. We saw him together at 12 noon, when he was quite unconscious, with commencing stertor, and quite incapable of being roused. The temperature in the axilla was 107·6°. There was no bath in the house, but we were at once provided with sponge and cold water, and, having stripped the patient, sponged him freely all over. Shortly afterwards some ice was procured, and while some pieces were put in the water to cool it, other pieces were rubbed gently over the whole surface of the body. For ten or fifteen minutes he still lay utterly helpless, and his breathing became even more stertorous; but after the lapse of that time, his temperature now being only 105°, he began to rouse a little and resist our attentions. By 12.30 Mr. Larkin had procured a full-sized bath from his house, and the patient was placed in it, though not without a good deal of struggling in a dazed sort of way, which of course we were very glad to see. He was, it appears, used to a cold bath, and seemed after a little to comprehend the argument of his wife that it was only a repetition of his ordinary morning proceedings. About 12.40 he appeared so thoroughly roused, the skin so cool, and at the same time his respiration and pulse were so quickened by the struggling which he unconsciously offered, that we removed him, dabbed him dry, and placed him in blankets. He now recognised his wife, and made even joking remarks. The pulse was 150, the temperature 98° in the axilla. Ten minutes later the temperature was 99·5°, the pulse 140. In bed, before the bath, while being sponged, and also in the bath, he passed a quantity of yellow fluid fæces. For the time he seemed out of danger, but knowing the possibility of a relapse of hyperpyrexia, and finding it was almost impossible to have him watched at home without putting them to a greater expense than they could well afford, it was decided to remove him to Guy's Hospital, which was only half a mile distant. He was therefore wrapped up in blankets, and carried down into Mr. Larkin's carriage. He sat up in the carriage, looking terribly collapsed, pale, and livid about the lips; but at 1.15 he was comfortably in bed in the clinical ward of Guy's Hospital under the care of Dr. Wilks, as I had no charge of beds at the time. On admission, his temperature was 101·2°, pulse 148; he was free from pain. At 2 o'clock, temperature 101·6°, pulse 132. He did not know that I attended him in the morning, or that he had ever seen me before. He was only just conscious, appeared to understand what was said to him, but answered questions slowly. At 2.30 P.M., temperature 102·4°, pulse 130, respiration 36 [illegible] was ordered half an ounce of brandy every two hours. His feet were rather cold, and he had some shivering. He was still free from pain, but was beginning to perspire a little at 4.30. The temperature was taken nearly every hour. Up to midnight it oscillated between 102° and 102·6°; it reached 103° at 2 A.M., and varied from that to 103·8° until noon on the 6th. Pains returned in the joints on this day; he was delirious, and slept but little during the night. The highest temperature on the following day was 102·8°, and again he was delirious at night. From this time he improved, and, though he had a slight return of pain and pyrexia on Oct. 21st, the latter never rose above 102°. He was out of bed on Nov. 7th, and left the hospital on Nov. 13th.

There is not the slightest doubt that this patient owed his recovery to the vigorous application of cold at a time when his temperature was 107·6° and he was already unconscious, with stertorous breathing. And though it is impossible to predict what may in the future be done by antipyretic drugs, the use of cold water and ice is still the most efficient means of reducing the temperature in these cases. We have a great advantage in large towns. Most that is required can be brought together in a short time. A bath could be probably procured by purchase or hire in time to be of value. Ice may often be obtained in a few minutes, and in the meantime, a mackintosh or a sufficient thickness of blankets or old linen having been placed under the patient to protect the bedding, he may be freely sponged with the coldest water that can be procured. Or, failing the bath or ice, cold water may be used in the form of a wet pack. The principle is the same in all cases, and that method must be employed which is readiest to hand, and which will most quickly reduce the temperature. In the present case, while waiting for the bath, a rapid and decided effect was obtained by rubbing the surface of the body with lumps of ice big enough to be conveniently held in the hand. In country practice, I can imagine the difficulties are much greater, especially in the summer; probably the wet pack, often repeated, would be most often serviceable.

It is of interest to note that this patient was comatose, with a temperature of 107·6°, and that after the temperature was reduced by cold it never again rose to a dangerous height. About the time of its occurrence two other cases were published with precisely these features—viz., coma, threatening death, when the temperatures were 107·2° and 107·4° respectively, and no second rise of temperature to hyperpyrexia. One was published by Dr. Sinclair in the *Edinburgh Medical Journal* for August, 1882, the other by Dr. Bates in the *British Medical Journal* for October 20th, 1883, and I think I have seen other similar cases recorded since. The fact that life can thus be saved in many cases by one great effort should lead us to make the effort in a determined way when the occasion arises.

St. Thomas's-street.

ONE HUNDRED CONSECUTIVE CASES OF ABDOMINAL SECTION.

BY GEO. GRANVILLE BANTOCK, M.D., F.R.C.S. ED.,
SURGEON TO THE SAMARITAN FREE HOSPITAL.

THE following table presents in brief the nature of the cases, with the number of each class, as also the recoveries and deaths:—

No. of cases.	Operation.	Recoveries.	Deaths.
50	Ovariotomy	49	1
9	Hysterectomy	9	—
15	Supra-vaginal hysterectomy	12	3
12	Removal of uterine appendages for disease	10	2
3	Removal of uterine appendages for fibroma	2	1
1	Removal of hydatids of peritoneum	1	—
1	Removal of retro-peritoneal cyst	1	—
1	Incision and drainage	1	—
7	Exploratory operations	7	—
1	Incomplete operation	—	1
100		92	8

Under the above heads I propose to notice the salient points of the more remarkable cases. Before proceeding to analyse the cases, I would make this general remark that I

Digitized by Google

have operated in every case of abdominal tumour that has come under my care, whether considered favourable or unfavourable, with the exception of fibroid tumours of the uterus and tumours diagnosed as malignant. In the case of the former of these, a careful selection has been made of such as, from the symptoms and the circumstances of the patients, seemed to me to justify the resort to operation; and these form only a small proportion of the number actually under observation.

Ovariotomy.—Under this head are comprised all cases of ovarian cystoma, parovarian cyst, and cyst of the broad ligament. Of the fifty cases, both ovaries were removed in sixteen instances. The second ovary was in a state of disease more or less marked, or was so injured in the removal of the primary disease as to necessitate its removal also. This state of disease varied greatly in extent. In one extreme the organ was in a state of atrophy, with commencing papilloma on its surface; its fellow, 2 lb. in weight, furnishing a typical example of papilloma, apparently originating on the surface. In another extreme, in the opposite direction, the organ was enlarged to 4½ lb.

Adhesions proper (i.e., the consequence of inflammatory action), more or less extensive, slight parietal or omental up to universal, were present in thirty cases, and enucleation had to be done in four cases. Of the latter the enucleation was single in two and double in two. Of the single cases, one was a suppurating cyst, weighing 3½ lb., enveloped in the left broad ligament, and the other was a large tumour of the left ovary, 17 lb. in weight, and in its separation between twenty and thirty ligatures were employed. There were several pints of free fluid in the peritoneum, and there was considerable pyrexia before operation. Of the two cases of double enucleation, in one the disease appeared to have taken its origin in the left side and to have invaded the right side, where, in the process of separation, the corresponding ovary was found as a flattened body, surrounded by connective tissue. In this case the appearances gave rise to the opinion that before the onset of the disease both ovaries were covered by peritoneum, and therefore situated *in* the broad ligament. As a result of this extensive enucleation, which involved the division of both Fallopian tubes, the uterus was deprived of all its lateral support, and, being at once a source of danger and a useless appendage, it was removed by supra-vaginal hysterectomy. Thus the operation was at once a double ovariotomy and supra-vaginal hysterectomy. The patient recovered without a bad symptom. The tumour weighed 15½ lb. In the other case the left tumour weighed 5 lb., and the right 1 lb.

The next most noticeable case is one of recurrent colloid. In the first operation, on Nov. 13th, 1883, the right ovary formed a tumour 31 lb. in weight, and the left one of 2 lb. Both were typical examples of the ruptured colloid tumour. The peritoneum was extensively infiltrated with this substance, and the omentum was very much thickened. In the second operation, on July 14th, 1886, a tumour, weighing 13 lb. and of the same character as the first, was found attached, by a medium-sized pedicle, on the left side of the pelvis, in the region of the sigmoid flexure, with which it had a very close connexion. The intestine was separated, and the pedicle was secured by double ligature in figure of 8. Strictly speaking, this can hardly be called an ovariotomy, but as the disease originated with the ovaries, I have thought it best to include it under this head, with this explanation. The omentum was now very much more enlarged by colloid deposit, and formed a mass of the size and shape of my two hands placed together palm to palm. In both operations the loose colloid was washed out with warm water, and in both the drainage-tube was used—in the first for 102 hours, and in the second for forty-eight hours.

Another remarkable case was that of a very fat woman, aged sixty-six years. In addition to a tumour weighing 16 lb., there was an enormous umbilical hernia measuring between 4 in. and 5 in. across, with the omentum extensively adherent. The sac was freely laid open in the median line, the omentum ligatured in several portions and divided; the sac was then dissected out and the wound closed by peritoneal sutures of fine silkworm gut (cut off short) and by deep sutures, and so loaded were the parietes with fat that for the thickest part my 3½-inch needles were only just long enough. The patient made an excellent recovery.

In five cases there was twisting of the pedicle. In two of these I diagnosed the condition from the fact that in each there was a history of acute mischief within the peritoneum (such as pain, vomiting, and fever) followed by marked diminution of the size of the tumour. Of course these tumours were extensively adherent.

In three cases the tumour was dermoid. In only one of these were there any adhesions; these, however, were very old and confined to the pelvis, in which the tumour, weighing 10½ lb., was extensively and firmly fixed. In this case it was necessary to wash out the pelvis with warm water and to use the drainage-tube, and although the tube was left in for over six days the temperature only reached 100·2°.

Rupture of the cyst occurred in seven cases. In one of these the contents were thick colloid; in one there had been hæmorrhage into the larger cyst, which had ruptured; one was a papillomatous cyst and all its fluid had been evacuated; and four were examples of the ordinary mucine colloid. One was a case of suppurating cyst enveloped in the left broad ligament, 3½ lb. in weight; and in one there was, in addition to a tumour of 22 lb. on the left side, a chronic abscess between the right ovary and its tube.

The drainage-tube was used in twenty-nine cases for periods varying from twenty-six hours to seven days. Contrary to an opinion recently expressed, the results go to prove that the drainage-tube does not irritate the peritoneum, and is not thereby a source of danger; for without a single exception the product of the tube gradually diminished until at last not more than half a drachm of pale, clear, amber-coloured or almost colourless serum was obtained, and furnished the indication for its removal. On the contrary, I have distinct evidence, both in my own practice and in that of others, to show that the drainage-tube may be removed too early, and a fatal result be thus brought about.

In twenty-two cases the peritoneal cavity, more especially the pelvic portion, was washed out with plain warm water, and no attempt was ever made to sterilise it, as it is called—that is, to deprive it of all or any of Mr. Lawson Tait's "thirty-six beasts." As a rule the temperature is such as to be agreeably warm to the hand; if there has been much sanguineous oozing from torn adhesions, the temperature has been raised to at least 110°; and if at any time the water offered me has been too hot, it has been cooled down by adding the ordinary water of the hospital. For the purpose of pouring in the water I have usually employed a pint jug with a spout. It is almost needless to say that I have not seen any evil results follow this practice, but, on the contrary, I believe, it has been of distinct advantage. It is especially useful in the case of effused colloid matter and of dermoid tumours that have ruptured in the course of their separation, and the water should be used very freely.

The only death in the series occurred in a woman aged fifty-six, who was in a state of great emaciation, with a chronic bronchial cough. The tumour weighed 13 lb., and had been once tapped. It was one of the cases in which the pedicle had been twisted, and severe hæmorrhage had taken place into the large cyst. The tumour was universally adherent to the parietes, omentum, pelvic cavity, and to about two feet of intestine with its mesentery, and many ligatures were required. So great was the oozing from the parietes that I was induced to employ the cautery to some of the more freely bleeding surfaces, but it failed completely, and I then closed the wound, leaving in a drainage-tube. The cough gave no rest to the injured parts within the abdomen, and the patient died in five days and a half. The post-mortem examination revealed some adhesive peritonitis and great congestion of the lungs. It would have been better, I imagine, to wash out the peritoneum with *hot* water and trust to the drainage-tube than to use the cautery in such a case. It will not be out of place to state here that the mortality of my last hundred cases is only 5 per cent.; that of the last ninety only three have died, that of the last fifty-five only one has died, and that the last forty-five have all recovered.

Hysterectomy.—By this term is meant the removal of a pediculated fibroid tumour of the uterus; that is, without opening the uterine cavity. It does not necessarily include the removal of the appendages. Of these cases there are nine in the table, with a clean record. In one of these the appendages were not removed. In two of the cases the pedicle, though of considerable thickness, seemed suitable for the ligature, and I proceeded to treat them in that way. For this purpose the pedicle was first compressed by very powerful forceps, then transfixed and ligatured. After cutting away the tumour in such a way as to leave the stump in the form of two flaps, I sutured these together; but before the process was completed the stump was already oozing. I therefore applied the serre-nœud, and the patients

Digitized by Google

recovered without causing a moment's anxiety. Thus all the cases were treated by the extra-peritoneal method, and with my modification of Koeberlé's serre-nœud; and when I state that all the cases that I have thus treated—thirteen in number—have recovered, I think it must be admitted that there is much to be said in favour of this method of treatment.

Supra-vaginal hysterectomy.—As the term implies, this class comprises all the cases in which the uterine body has been involved in the disease, and has been removed at or about the level of the internal os. They are of a much more serious nature than the former, with which they should not be classed. Of these there are fifteen, not including the case of double ovariotomy and supra-vaginal hysterectomy already referred to amongst the ovariotomies. All were treated by the extra-peritoneal method. One patient, aged forty-three, died in thirty-three hours with acute suppression of urine. The liver and kidneys were found in a state of extreme fatty degeneration. Before the operation the specific gravity of the urine was only 1013, and there was a trace of albumen. But the sufferings of the patient were such—due apparently to cystiform degeneration—that I felt compelled to attempt her relief in the hope that the kidneys might not be too much diseased. But the urine became more scanty and more and more charged with albumen, and finally the secretion ceased with the advent of evidently fatal symptoms. The second, aged forty-six, also died with suppression of urine on the seventh day. On the fifth and sixth days the temperature was normal, but the pulse was 120 and there was albumen in the urine, which was still secreted in fair quantity. By the end of the sixth day, however, it became scanty, and within a few hours of death the kidneys quite ceased to act. These organs were large, soft, and slightly congested, and the capsules were adherent. The spleen was very soft and friable, breaking down like a blood clot. The third, aged forty-four, died on the sixteenth day. The posterior uterine wall was enormously hypertrophied, so that the diameter of the section measured over three inches, and at the post-mortem examination the lower segment of the uterus presented the appearance of cystiform degeneration, the contents becoming purulent. It will be observed that two of these cases were almost of the same age—a time of life when, in my experience, one is most likely to meet with latent kidney disease, which, as it were, springs a mine on the operator; for the evidence of this disease is not sufficiently definite to compel the surgeon to refuse operation, when other symptoms and signs seem to demand it.

Removal of the uterine appendages for disease.—In eleven out of the twelve cases the operation involved both sides on account of double disease—chiefly the result of inflammatory action, such as pyo-salpinx and obstruction and adhesion of the tubes. In one of these there was a large hæmato-salpinx on the right side, and occlusion and adhesion of the tube on the left. One case was remarkable for the coexistence of inflammatory obstruction of the tubes and cirrhosis of both ovaries, and this condition was characterised by persistent pain and intense dysmenorrhœa. Another case was remarkable for a healthy condition of the tubes and extreme atrophy of the ovaries, and characterised by persistent pain and complete absence of menstruation. The patient, in this instance, was a married woman, aged forty-four, the mother of two children. Menstruation did not return after the birth of her second child, eleven years ago. For three years after that she was troubled on and off with pain in the left groin, gradually becoming more continuous and severe. For some weeks she was in one of the general hospitals. For months at a stretch she attended the out-patient department of several hospitals. Finally, she came under the care of Dr. Amand Routh in the out-patient department of the Samaritan Hospital, and after prolonged treatment she was transferred to me on account of persistent pain in both groins, of such severity as to unfit her for the discharge of her household duties. The operation confirmed my diagnosis, for both ovaries were in a state of extreme atrophy. One, with its tube, weighed only 60 gr., and the other 65 gr., the greater proportion of these weights being contributed by the appendages. The result has been complete relief from the pain and the re-establishment of the patient's health.

Chronic ovaritis, with enlargement of the organ is represented in the case of a married woman, aged twenty-six, the mother of one child fifteen months old. Leaving her dying consumptive husband, whom she was no longer able to [illegible], she entered the hospital, seeking relief for persistent and severe pain in the left groin. Menstruation was irregular and scanty, and was both preceded (for two or three days) and accompanied with severe pain in the left groin and leg. The left ovary was readily felt on examination, large and prolapsed, and on exposure presented a white and glistening appearance. It weighed over ½ oz., and it was evident that ovulation had been completely arrested. There was also a small parovarian cyst as large as a hazel-nut. The right ovary and its tube were quite healthy, and were not removed. Relief was immediate, and in three weeks the patient returned home and nursed her husband till his death. She is now in perfect health.

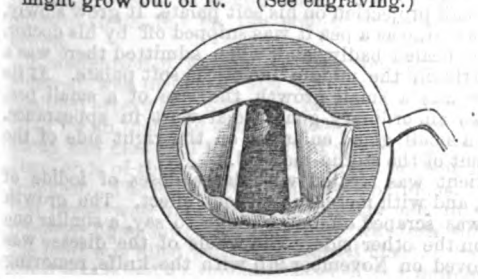
Hydro-salpinx and chronic salpingitis were combined in one instance.

In two of the cases of double operation menstruation has not been arrested. One of these is a very remarkable case. The patient, an unmarried lady aged twenty-six, had suffered for many years from persistent pain and severe dysmenorrhœa, with somewhat irregular and scanty menstruation. The tubes resembled small sausages filled with caseous matter, and were very adherent. They were removed close to the uterus along with the ovaries. Menstruation is now very regular, *and quite painless*, and the flow is more abundant and more healthy in character than she remembers it. The operation was performed in October, 1885. The second case is that of a single lady aged twenty-six, who had suffered from pelvic pain for several years, as the result of being upset in a cab. For three months she had been under treatment by rest, &c. Menstruation was very painful; the uterus was in a state of retroversion + flexion, and she had become subject to attacks of trembling of a distressing character, which were very readily induced by any interference with the uterus. I first saw her in consultation with a distinguished obstetrician, who had exhausted all his resources in his efforts to relieve her. The result of the consultation was the decision to recommend the removal of the appendages. What that involved was explained in all its bearings, and the patient at once—that is, within twenty-four hours—assented. The version and flexion were removed by the operation. Menstruation returned after the usual interval, but was painless.

Of the twelve cases two died, one on the fourteenth day and the other on the eighth. In the first case the operation was a very difficult one, from adhesion of the omentum to the parietes in the line of incision and to the uterus and brim of the pelvis, and from adhesions of the tubes and ovaries. For six days the patient went on most satisfactorily, the temperature never exceeding 99·8°, and the pulse for the greater part of the time beating 84. At the end of this time she was moved to the convalescent ward—i.e., on the seventh day,—where she developed a severe attack of catarrhal jaundice, which continued to the end. The second case was that of a single woman aged twenty-nine, who had been an invalid for three years, and had undergone a great variety of treatment. For thirteen weeks she had been in a country hospital without relief. When she first came under my notice I refused to operate, as there was nothing to be detected but the slightly enlarged and tender ovaries, especially the left. After five months' further treatment the persistent and disabling pain from which she had so long suffered was in no degree relieved, and she was admitted into the hospital, for the second time, in May, 1886. Both ovaries were affected with chronic ovaritis, and the right was beginning to atrophy. In neither was there any evidence of recent ovulation. There was no difficulty in the operation, but there was very free bleeding from the parietes. On first removing the dressings on the fourth day, it was seen that there had been rather severe bleeding from the middle of the wound, where one of the sutures had slipped from cutting off one of the ends of the suture too short, and between the lips of the wound there was a considerable blood clot. On the seventh day, owing to unfavourable symptoms supervening, and finding that a probe passed from the hæmatoma into the peritoneal cavity, I opened up the lower portion of the wound including the blood sac, and found some dark fluid in the lower abdomen and pelvic cavity. This was well washed out with warm water, and a drainage-tube inserted; but it was too late, for the patient died on the following day. It was quite evident that the fatal result was due to hæmorrhage from the parietes, occurring before the peritoneal surfaces had united.

Removal of the uterine appendages for fibroma.—During the last eighteen months I have only seen two cases in which I have felt justified in proposing this operation.

Digitized by Google



Many cases have been under my observation, and in all I have been able to afford relief either by intra-uterine medication or by constitutional treatment. Whether any of these may ultimately require more active interference remains to be seen. Of the three cases operated on, the first was that of a married woman, who had a multiple fibroid mass of about 1 lb. or 1½ lb. in weight springing from the back of the uterus by a thick and very vascular pedicle, besides quite a colony of small fibroids growing on the fundus. I should have preferred to remove the mass, but the pedicle was too thick and vascular for the ligature, and was in such a position that its extra-peritoneal treatment would have been exceedingly difficult—rendered more difficult by the presence of the numerous small growths, sticking, as it were, on the fundus; so that I had to carry out my first intention by removing the appendages after replacing the mass. The final result is, of course, not yet known. In the second case the condition of things was very obscure, and from the pain felt in the left ovarian region, as well as the physical signs, I believed I had to do with a case of disease of the appendages. The abdominal section revealed several small fibroids in the uterus as the cause of the menorrhagia, and a cancerous mass of small size over the sigmoid flexure. I removed the right appendages, but the left were so closely attached to the cancerous mass that I dared not interfere with them. The patient recovered without a single drawback, and went home in three weeks. In the third case the patient was a single woman aged forty-two, who was in a state of extreme anæmia from menorrhagia due to intramural fibroids. Both pedicles were very short, and on the left side the sigmoid flexure was very much dragged upon when the ligatures were tied. This patient died on the fourteenth day with symptoms of gradually increasing obstruction, having progressed most favourably for the first six days.

(To be concluded).

APHONIA DUE TO SUBGLOTTIC GROWTH (? CONGENITAL); OPERATION; CURE.

BY G. A. CARPENTER, M.B. LOND., M.R.C.S., &c.,
REGISTRAR AND CHLOROFORMIST TO THE EVELINA HOSPITAL FOR CHILDREN.

LOUISA B——, aged eighteen, brought a patient to the Evelina Hospital on April 19th, 1886, and the resident medical officer, Dr. Albert Martin, noticing that she herself was almost voiceless, asked me to make a laryngoscopic examination. She stated that she had been told that "her cry when a baby was a peculiar one," and that she had been only able to speak in a whisper up to the age of ten years. She then went to a boarding-school in the country; her voice became hoarse about that time, and since then has always remained in the same condition. When fourteen years of age she sought advice from a chemist, who stated that there was no cure for her complaint, but that she "might grow out of it." (See engraving.)

On making a laryngoscopic examination, a pedunculated tumour about the size of a split pea, with somewhat elongated pedicle, of a pink colour, and lobulated surface, was seen situated at the anterior commissure. The pedicle of the tumour disappeared under the right vocal cord, and was apparently attached just below it, near its junction with the thyroid cartilage, and arising from the latter. During respiratory movements the tumour moved backwards and forwards with the current of air, now appearing above the cords, and now descending into the subglottic region, almost out of sight. The breathing space was diminished by about a fifth during expiration. There was no dyspnœa. The vocal cords were slightly injected, and during attempts at phonation could not be approximated on account of the tumour wedging itself between their anterior attachments. Movements of abduction were perfectly free. The patient was directed to attend for treatment on April 23rd.

April 23rd.—Tumour easily visible. The larynx was painted with a solution of cocaine, fifteen grains to the ounce, and an attempt made to grasp the growth with Mackenzie's forceps, but without success, partly owing to the broad shank of the forceps blocking the view in the laryngeal mirror, and partly to difficulty experienced in getting the blade well into the narrow commissure, the space afforded being too narrow to accommodate the forceps. After several attempts, it was seen that, owing to the above reasons, the growth could not be seized, and the patient was ordered vapor benzoini for inhalation, and told to attend every other day in order that she might accustom herself to the use of instruments, the introduction of which could not at first be tolerated.

May 4th.—On this date the patient again attended for operation. My friend, Dr. Albert Martin, since the 23rd ult., had been practising her with instruments without cocaine; and so efficiently had this been performed that she could now without difficulty tolerate their use. The larynx was painted with a solution of cocaine, fifteen grains to the ounce; and about ten minutes after its application the tumour was grasped at the first attempt with Mackenzie's tube forceps and removed with ease. It presented a lobulated appearance, was of a pink colour, of fairly soft consistence, and had apparently come away in its entirety. In consequence of the amount of blood about the parts, it was impossible to see whether its removal had been completely accomplished. Its structure seemed to be of the nature of a soft fibroma. Shortly after its avulsion the patient spoke comparatively clearly. Vapor benzoini was ordered for inhalation, and she was directed to attend again the next day.

5th.—Laryngoscopic examination shows no trace of the growth. The vocal cords approximate completely in the mid line, and the patient speaks in a natural voice, much to her delight. As there is some injection of the cords, the patient is to attend daily for a week for topical applications of chloride of zinc, fifteen grains to the ounce.

12th.—The vocal cords are of normal colour now, and the larynx is healthy in every respect. Unfortunately, owing to the small growth being mislaid amongst many pathological preparations, the microscopical appearances of the tumour cannot be given.

CHARING-CROSS HOSPITAL.

STRANGULATED CONGENITAL HERNIA WITH RUPTURE OF THE INTESTINE; HERNIOTOMY; ENTORAPHY; CURE; REMARKS.

(Under the care of Mr. BARWELL.)

THE peculiarities in the subjoined case were: The unusual length and obliquity of the canal (this resulted from the very recent date of the hernia allowing of no time for the usual approximation of the internal to the external ring); the number of bands running across the intestine within the funiculus of the tunica vaginalis and the tension of the rings themselves, the early rupture being doubtless due to these causes; the edges of the rent had the appearance of being more than twenty-four hours old; the extreme ease with which recovery took place; the remarkable appearance of the natural healing process by the production of a beautifully opalescent and transparent layer of lymph creeping over and covering in the sewn-up rupture. It is

Digitized by Google

rare that so good a view of a reparative process can be watched in the human subject.

T. B——, aged twenty, was admitted on Nov. 13th, 1886, at 11 P.M. The patient is unaware of having had any rupture as a child, but at Christmas last a swelling suddenly appeared in his groin and scrotum. This was accompanied by dragging pain in the abdomen and a sense of sickness. A week ago he jumped from a cart and immediately felt a pain in the groin and testicle, and found considerable swelling in that neighbourhood. Soon after he was sick. Next day and again a day or two after, he tried to work, but was unable to do so, and has been several times sick, more especially during this day. The bowels have not acted since the accident.

Mr. Barwell being sent for, he saw the patient shortly after admission. He had a small weak pulse; the skin was cool and somewhat clammy. He complained of much pain in the scrotum, groin, and umbilical region. He had not been sick since admission, nor had he hiccough. The hernial swelling distended the inguinal canal and the scrotum very considerably; it was very tense and tender; the skin over it was red. Herniotomy was at once performed. The sac was reached without difficulty and opened; within it was nothing but a much distended and congested coil of intestine, which lay in contact with the testicle. The external ring was excessively tense; when this was incised the inguinal canal was not found shortened, as is commonly the case with large herniæ, but was of normal length and obliquity. A little inside the ring, the gut showed a more excessively congested patch, running across which was a rupture about half an inch long and ragged, the edges of mucous membrane that protruded being ulcerated. After several bands in the inguinal canal had been divided, and the very tense internal ring incised, it became possible to draw that part of the intestine into better view. The opening was closely stitched, after Lemberg's method, with fine catgut. A stitch was passed through the peritoneal and partly through the muscular coat, a little beyond the highly congested part, and left long, so as to hang from the wound; then all the gut was returned from both ends, leaving the ruptured and sewn part bare, just at the mouth of the ring. This was covered with a double layer of protective, and the whole was dressed with carbolised gauze. Ordered half a grain of opium every fourth hour.

Nov. 17th.—The patient has had no disquieting symptom. Over the ruptured intestine, and covering in the stitches, was a layer of lymph. The highest temperature was 99·8°.

19th.—The temperature rose to 102·4°. On examining the wound the scrotum was found distended, and a little dark blood was found to come from one part near a stitch. The incision here (the front of the scrotum) was opened, and a dark clot turned out. No bleeding point could be discovered, and the wound was closed again.

Dec. 20th.—With the exception of the oozing above mentioned, which did not recur, the patient has had no bad symptom. The wound was rather slow of healing, but he has been practically well for several days.

NEWCASTLE-ON-TYNE INFIRMARY.

DIFFUSED TRAUMATIC ANEURYSM OF THE ANTERIOR TIBIAL ARTERY OF TEN WEEKS' DURATION; ATTEMPTED LIGATURE; AMPUTATION.

(Under the care of Mr. PAGE.)

THE following notes are by Mr. F. P. Maynard, M.B., house-surgeon.

John M——, aged sixteen, was admitted on Nov. 18th, 1886, with the following history: On Sept. 13th, while staying with some friends in Lancashire and playing with other boys, one stabbed him with a penknife (blade two inches long) in the left leg, at the junction of the middle with the lower third, about half an inch outside the crest of the tibia, in a direction backwards and inwards. It bled freely, spurting out (not in jets) dark blood, he says. The leg swelled. He was sent to bed and poultices applied. Four days after, on getting up, he had pains in the leg, and the swelling increased a little. The wound healed, the swelling remained, and on Oct. 4th he returned home. The next day suddenly great pain came on, and the swelling again increased. It was poulticed, and a fortnight later his doctor opened it, when much blood clot was removed, and a few drops of fetid pus. The bleeding, which was considerable, was stopped by pressure. It bled at intervals until Nov. 17th, the day before admission, when free hæmorrhage took place.

On admission the boy was very anæmic and emaciated, with a poor pulse and no appetite. The lower and half of the middle third of the leg were occupied by a swelling about eight inches in length, uniformly fluctuating and soft; and situated about its middle was a small wound, from which blood was oozing, a drop at a time. This swelling communicated distinctly with a similar but smaller one behind the inner side of the tibia. Both were without pulsation. Pulsation was absent in the anterior tibial artery below, but present in the posterior tibial. The foot was œdematous. Pressure was applied and the oozing stopped.

Nov. 24th.—Hæmorrhage occurring, under chloroform Mr. Page enlarged the opening and cleared out about one pound of blood clot, with a tourniquet on the femoral. The anterior tibial artery could not be found, but two or three bleeding venous points were tied, and afterwards one small artery, and the bleeding stopped. The posterior portion of the sac was also opened, but nothing found to tie. The tibialis anticus was completely split up and separated from the tibia, which in one place, the size of half a crown, was eroded, and the interosseous membrane was wanting for several inches. There were no signs of suppuration anywhere except at the old incision. The leg was elevated and dressed, and permission for amputation obtained should it be necessary. At night the bleeding recurred, and the leg was amputated through the middle third by lateral flaps (Bryant's), so as to utilise the incisions previously made into the aneurysm, and the flaps brought together by a continuous catgut suture.

The leg did well, except that pus collected over the inner side of the end of the tibia, and the patient was allowed to go out on Dec. 12th. On the 15th oozing of blood came through the incision. At 10 P.M. excessive bleeding took place, and, under ether, Mr. Maynard opened up the stump, having to cut through firm cicatricial tissue, turned out the clot, and tied some bleeding points, only one of them arterial, and that a small vessel. As the end of the tibia was necrosing, a piece of it was sawn off, some unhealthy granulations scraped, and the flaps sutured. After operation the patient was much collapsed, and rallied slowly.

Jan. 20th, 1887.—Patient has recovered uninterruptedly, gaining flesh rapidly.

Feb. 8th.—a small exfoliation has come away from the tibia. The size of a small button.

25th.—Wound all but healed. Is going to a convalescent home.

EPITHELIOMA OF THE SOFT PALATE,

(Under the care of Mr. PAGE.)

The notes of this case are also furnished by F. P. Maynard, M.B., house-surgeon.

E. D——, aged twenty-seven, a fireman, was admitted on Oct. 7th, 1886. Family history good; habits good, and no history or sign of syphilis. Last April he felt with his tongue a small projection on his soft palate. It grew slowly, and when as large as a pea it was snipped off by his doctor. The wound healed badly, and when admitted there was a small cicatrix in the middle line of the soft palate. At its left border was a small growth the size of a small pea, exactly like an ordinary gonorrhœal wart in appearance. There was a small gland enlarged on the right side of the neck in front of the sterno-mastoid.

The patient was treated with large doses of iodide of potassium, and with mercury, without effect. The growth therefore was scraped off, but, strange to say, a similar one appeared on the other side. The whole of the disease was freely removed on November 9th with the knife, removing the whole thickness of the palate. The wound did not heal well, and the disease returned in it within a month, and the gland in the neck enlarged rapidly. He went home on December 23rd.

On Feb. 1st the man came again to the hospital. The whole of the right two-thirds of the soft palate was a mass of foul epithelioma, which had spread down the right arch to the tonsil, which was itself a mass of disease. He had lost flesh, and looked very ill and anæmic. The gland in the neck had enlarged, and was now as large as an orange; it was adherent to other enlarged glands. They were still encapsuled, but under the sterno-mastoid.

WOLVERHAMPTON AND SOUTH STAFFORDSHIRE GENERAL HOSPITAL.

RUPTURE OF THE POPLITEAL ARTERY AND VEIN; AMPUTATION; REMARKS.

(Under the care of Mr. VINCENT JACKSON.)

WE are indebted for the following notes to Mr. J. Harley Gough, house-surgeon.

On Nov. 24th, 1886, at midday, T. L——, a miner, aged twenty-one, was working down a coal-pit, when a quantity of rock and gravel fell on his back and right popliteal space. He was knocked down, and remained unconscious for some minutes. When pulled out of the débris the back of his right knee immediately began to swell, the swelling rapidly extending up the thigh and down the leg. He had severe pain in the limb for some hours, but it gradually became easier.

On admission the next day, the right leg and thigh were greatly swollen, hard, tense, elastic, and shining, from about two inches below Poupart's ligament to the toes. The swelling was especially marked in the lower half of the thigh, back of knee, and calf, as the following measurements will show:

	Round calf.	Over patella.	4in. above patella.
Sound limb	11½in.	12¾in.	15¼in.
Injured limb	15in.	17in.	17in.

There was considerable ecchymosis behind the knee and upper part of the calf. The foot and leg were much colder than those of the opposite side, and sensation was blunted. The foot was of a darkish-purple colour, reaching as high as the ankle. Patient did not complain of pain except when the leg was moved. No pulsation could be felt in the popliteal space or in the arteries below. There was no fracture or dislocation. The man was very anæmic; pulse weak, but regular, 110. Tongue clean. The patient was put to bed and the limb enveloped in cotton-wool, elevated, and hot bottles put to the foot and leg.

Dec. 1st.—The condition of the limb remains much the same. The patient has some pain in the knee at times, which is relieved by opiates. The foot is quite cold, and is getting darker in colour. Pulse 120; temperature 99·8°.

4th.—The foot and lower part of the leg are distinctly gangrenous. The temperature has been slowly rising for the past few days. The swelling of the limb has neither increased nor diminished. Amputation was deemed advisable, and the patient having consented, the limb was removed about three inches above the condyles of the femur by means of long anterior and short posterior skin flaps. The subcutaneous tissues and inter-muscular spaces were filled with dark clotted blood. The femoral artery was patent, and did not contain a clot.

After the operation the patient suffered much from collapse, but towards evening recovered; he had a good deal of pain, which was relieved by morphia. The wound was dressed twice daily for some days, on account of the discharge. The stump slowly became less in size and softer, and on Dec. 24th he got up for the first time. The patient made a good recovery, and went out convalescent on Jan. 26th, 1887; he would have gone home sooner, but, unfortunately, fell on the end of his stump some days before.

Examination of the limb.—After the operation the limb removed was dissected, and a transverse rupture of the popliteal artery and vein was found, the ends being separated for an inch and a half. The seat of the rupture was about the centre of the popliteal space. The proximal and distal ends of the artery were retracted in their sheaths and occluded. The ends of the vein were patulous. The popliteal nerve was intact, and apparently not injured. The posterior ligament of the knee-joint was torn through, and the joint was filled with semi-clotted blood. Extravasated blood was found everywhere between the muscles and also subcutaneously, the subcutaneous layer being more than half an inch thick in places.

Remarks.—Rupture of the popliteal artery and vein without external wound is a rare injury, only very few cases being recorded. Complete rupture of the artery alone is uncommon, but occurs more frequently than rupture of both vessels. The signs and symptoms are much the same in both cases—viz., rapid swelling of the leg and thigh, no pulsation in the popliteal space or in the vessels below, and coldness of the limb. There are two lines of treatment: (1) ligature of the ruptured ends of the vessel or vessels; (2) amputation of limb. In the first method it must be difficult to apply a ligature to the torn ends of the artery, and even when done the circulation may not be established, owing to the pressure of the extravasated blood on the collateral branches, although tension may be considerably lessened by incisions. Experience shows that amputation of the limb is followed by the best results, and this should either be done as early as possible or when gangrene becomes evident, and without waiting for the line of demarcation. Ligature of the femoral is obviously of no use in these cases.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Gouty Parotitis and Gouty Orchitis.—Empyema, with Pulmonary Gangrene, following Enteric Fever, treated by Perflation.

AN ordinary meeting of this Society was held on March 8th, 1887, Mr. G. D. Pollock, President, in the chair.

A paper on Gouty Parotitis and Gouty Orchitis, by Dr. DEBOUT D'ESTRÉES of Contrexéville, was communicated by Dr. Garrod. The object of the paper was to fill a lapsus in the literature of gout, in so far as this disease affects the glandular system, more especially the parotids. There are genuine attacks of gout having their seat in the glands and alternating with articular manifestations. The following case was related: X——, aged sixty-eight, a well-marked gouty subject, was suddenly attacked with swelling at the angle of the jaw, which resisted ordinary treatment, and only disappeared on the invasion of the knee on the opposite side. The second parotid and the other knee were also attacked subsequently. Some little induration of the parotids remained, together with salt taste in the mouth, due probably to the presence of urates in the saliva secreted by these glands. Similar cases by Drs. Garrod and Rotureau were also referred to. These cases were promptly relieved by a tincture of fresh colchicum flowers, fifty drops thrice daily. The author had only seen two cases of gouty orchitis, which, resisting treatment, subsided spontaneously on the appearance of gout elsewhere. The left testicle is most frequently affected, but not invariably. He had not seen it in both parotid and testicles in the same patient.—The PRESIDENT had never seen parotitis in association with gout, but had met with cases of orchitis in men of advanced life who were the subjects of articular gout.—Sir DYCE DUCKWORTH thought that gouty parotitis must be a great rarity. Sir James Paget had remarked on the great immunity of the lymphatic tissues from gouty inflammation. He considered that the correctness of the diagnosis was proved in these cases by the effect of the treatment and by the fact that the inflammation of the parotid gland or testicle alternated with articular pain.—Mr. STEPHEN PAGET quoted cases which showed that there was an association of parotitis with dyspepsia and abnormal nervous symptoms. He asked whether it was possible that the parotid lesion could be aided by a faulty state of the gland induced by a condition of chronic dyspepsia.—Dr. BERNARD O'CONNOR referred to a case under his care of gout associated with swelling of the sublingual glands.—Dr. GARROD had collected 2000 cases of gout, but there was not one with a history of parotitis. He had since met with a case—a man of sixty-five, a gouty subject, who was attacked with acute inflammation of both parotid glands—which subsided without suppuration. He thought that cases of suppurative parotitis could not be of true gouty character. He had seen many cases of orchitis in which the swelling vanished on the appearance of arthritic gout.—Dr. D'ESTRÉES, in reply, said there was a slight dyspeptic history in his patient. Some saliva examined during the attack was acid, and gave a murexide reaction. Since he had written his paper he had heard of another case, under the care of Professor Damaschino of Paris, in which the primary gouty manifestation occurred in the parotids. The cases might induce surgeons to employ medicinal means before resorting to operative interference.

Dr. WM. EWART and Mr. R. FITZROY BENHAM read a case of Empyema with Pulmonary Gangrene following Enteric Fever, treated by Perflation. The patient, a male, aged ten years and eleven months, was seized with enteric fever (due

Digitized by Google

probably to drain infection) on April 23rd, 1886. The symptoms were not unusual in character, but severe in degree, especially the delirium. The treatment adopted by Mr. Benham consisted of quinine, which proved ineffectual, and of antipyrin, which appeared to relieve the pyrexia and the delirium. The patient was convalescing at the end of the fourth week, when peritonitis supervened, soon followed by left pleuritic pain. Within a week the signs of left empyema were fully developed, the exhaustion was extreme, and the dyspnœa bordered on asphyxia. On June 11th aspiration was made, and three-quarters of a pint of thick shreddy pus removed, with relief of the most urgent symptoms. The following day the chest was opened freely in the anterior axillary line (fifth space) and in the scapular (ninth space), a large quantity of pus escaping. Free discharge continued, but no injection was used. On June 15th perflation was performed under spray in the manner depicted in THE LANCET (July 31st, 1886), the appliances being elastic tubing, a Woolffe's bottle containing carbolic acid solution (1 to 10), and a hand-ball bellows. The air was delivered into the centre of the chest through the anterior opening, and allowed to escape only at the posterior. The result was the expulsion of fetid pus, of a piece of necrosed lung, and of heavy false membranes. A smaller mass of membrane was expelled by perflation the next morning, and a small piece on the third day. From this day the fetor ceased, and the amount of pus decreased rapidly. On the eighth day the discharge was turbid-serous, and it remained serous to the end. Both wounds were closed on the thirtieth day from the date of incision, and on the twenty-fourth from the first perflation. Among the advantages obtained in this case by the method employed were the following: 1. Early removal from the chest of putrid residues. 2. Presumably considerable shortening of the period of suppuration as a result of (1). 3. Avoidance of permanent atelectasis and of eventual resection of ribs as a result of (2). 4. Avoidance of deformity as a result of (3). 5. Daily dressings free from discomfort and from wet (excepting the spray). 6. A drier state of the cavity and of its coverings than is allowed by fluid injections, with absolute sweetness of the discharge.—The PRESIDENT asked what was the advantage of perflation over free incision at the most dependent part, with, if necessary, excision of the rib.—Sir DYCE DUCKWORTH believed the practice of washing out the pleura was a mischievous one. He would use perflation in future in that class of cases where, having made a free opening with antiseptic precautions, the patient did not progress satisfactorily.—Mr. GODLEE thought the case peculiar, in that a piece of gangrenous lung was discharged without a history of previous fetid expectoration. He considered that a free opening posteriorly without perflation would have met the needs of the case. Injecting the pleura was a mode of treatment now passing out of fashion. In cases requiring it, he recommended blowing iodoform into the pleural cavity with an insufflator.—Mr. BENNETT inquired what was the result of treatment in adults and in those cases which, previous to its use, had not done well. He could not recommend its adoption in general surgery, for in one case in which he perflated an abscess in the thigh, he produced extensive subcutaneous emphysema.—Mr. R. W. PARKER had published a paper in the Society's Transactions many years ago advocating a similar method to this. He had abandoned injection, and made a single large opening, into which a double drainage-tube was passed.—Dr. DAWTREY DREWITT likened perflation to the schoolboy practice of "blowing" an egg, and pointed out the difficulty of separating the inner membrane from the shell by that method.—Mr. HOWARD MARSH said he adopted the following method of evacuating an empyena:—First make an opening high up; from this pass a catheter, and feel the lowest part of the pleura; then make a large opening at this lower point, and allow the upper one to close. He believed washing out the cavity was not advisable, and, indeed, unnecessary. He objected to the insufflation of iodoform, which, he thought, might act as a poison. In excising a rib, if the periosteum were left deformity would be avoided.—Dr. SANSOM said the air would not be sufficiently purified by being blown through water. He advocated passing the warmed air over blotting-paper, cotton-wool, or sponge, saturated with pure carbolic acid.—Mr. PEARCE GOULD thought the value of the method could scarcely be judged from one favourable case. He considered the best treatment was a single free opening in the sixth or seventh interspace, and in the post-axillary line.—Dr. EWART, in reply, agreed as to the value of a large opening. He believed perflation useful in recent empyema to discover whether loose pieces were present. In older cases it might be beneficial by effecting the removal of an irritant. He had treated five cases of left-sided empyema, and perflation in them had produced no effect on the heart. In using this method in general surgery care should be taken to have free openings, so as to avoid undue pressure.

PATHOLOGICAL SOCIETY OF LONDON.

Adenosarcoma of Tongue, with Calcifying Nodule in Centre.—Alveolar Sarcoma.—Malarial Diseases of Liver and Spleen.—Extra-uterine Pregnancy.—(?) Cirsoid Aneurysm.—Cholesteatoma at Base of Brain.

AN ordinary meeting of this Society was held on the 3rd inst., Sir J. Paget, Bart., F.R.S., President, in the chair

Mr. R. J. GODLEE showed a specimen of Adeno-sarcoma of the Tongue, with ossifying (? calcifying) nodule in the centre. It was a hard nodule of the shape and size of a small pisiform bone, and having the appearance of bone, removed from the centre of a tumour on the under surface of the tongue near the tip. The patient was a woman aged twenty-four, a patient of Mr. S. N. Bruce. The tumour had only been noticed five weeks, and had already sloughed over an area the size of a shilling on the under surface, through which the hard mass was removed with a sinus forceps. Some weeks afterwards the tumour was excised with scissors. The growth was an adeno-sarcoma, the sarcomatous tissue being abundant and highly vascular, and the adenoid tissue arranged in acini of varying size lined with square epithelia. The acini were in parts dilated into small cysts containing a brownish structureless material, in which were nuclei (? leucocytes). The hard mass on section had roughly the appearance of imperfectly formed bone. Mr. Godlee suggested that the tumour, which he believed to be unique, was connected with a mucous gland from 7 to 10 lines long, described by Nuhn in 1845 and by Blandin at an earlier date, in this situation lying beneath a few fibres of the styloglossus. A specimen of this gland, prepared by Mr. Pearson at the College of Surgeons, was shown. It was pointed out that the presence of bone would be very remarkable, but it was added that the microscopical examination was not unequivocal, and that it might, after all, be merely a mass formed by a cretaceous or calcareous change in the contents of one of the cysts contained in the tumour.—Mr. STEPHEN PAGET observed that the tumour seemed to be very similar to some tumours found in the palate. In the age of the patient, the chronic course of the disease, the superficial ulceration and calcification, he saw points of resemblance. He thought such a case might be explained on the hypothesis that there were vestiges of gland tissue in the tongue as well as in the palate.

Mr. G. R. TURNER read a case of Alveolar Sarcoma. The tumour grew in the left loin of a man, aged twenty, and proved fatal seven months after it was first noticed. Its connexions were such as not to admit of removal. It sprang from the bone of the twelth rib, from the periosteum of the transverse processes of all the lumbar vertebræ, and from the crest of the ilium below. It was not encapsuled, and had extended inwards, almost surrounding the aorta and inferior vena cava, completely enclosing the left common iliac vessels, converting the pancreas, lumbar glands, and psoas muscles on the left side into masses of new growth. Secondary deposits were found in connexion with the diaphragm, omentum, mesentery, meso-colon, and pleura. Microscopical specimens and drawings by Dr. Délepine were shown. The tumour was a well-marked instance of alveolar sarcoma, the cells being chiefly oval or pyriform; the stalk of the latter could be seen to be continuous with the fibrillated septa of the stroma. The diaphragmatic growth showed the muscle fibres separated by an alveolated stroma containing cells. And the same appearances were observed in the secondary pulmonary growth. Reasons were given for regarding the growth as sarcomatous rather than carcinomatous, and the relations of lymphadenoma with alveolar sarcoma were discussed. In reply to Dr. Norman Moore, Mr. Turner said the suprarenal body was not invaded; the growth passed behind the left kidney, but neither it nor the suprarenal body was involved.

Dr. NORMAN MOORE showed specimens of Malarial Disease

Digitized by Google

of Liver and Spleen, with Tuberculosis. A greatly enlarged spleen weighing 60 oz., and a liver weighing 120 oz. Naked-eye sections of the spleen showed numerous white specks throughout it, and there were some larger masses which had become caseous. None of the masses had injected edges. The liver contained many similar small white masses. The whole peritoneum was covered with similar masses, some of them caseous. The mesenteric glands were caseous. There were some small caseous masses in both kidneys. A layer of caseous material, a quarter of an inch thick, surrounded the upper part of the rectum. In all the lobes of the lungs were scattered groups of masses exactly resembling those in the liver. One abdominal caseous gland had broken down in the middle. Under the microscope the masses in the liver and spleen were seen to consist, some merely of caseous material, others of collections of small cells, some near bloodvessels, others in the midst of the gland tissue. Besides the small round cells, a few multinucleated cells could be seen in some of the masses, but no true giant cells. After several examinations no bacilli were found. The liver showed some general connective tissue increase. The spleen showed collections of cells precisely resembling those in the liver, and also many pigmented patches, a large connective tissue increase, a general infiltration by blood-cells resembling that seen under the microscope in nutmeg liver. The patient was a man aged twenty-one years, who was in St. Bartholomew's Hospital, first under Dr. Moore's care and afterwards under Dr. Andrew. He had worked on a railway in Cape Colony from 1880 till 1884, and in 1883 was laid up for a year with tertian and quotidian ague. He went to Ceylon, and had dysentery on the voyage. From 1884 he had noticed his greatly-enlarged spleen. After returning to England he had fever again. He had never had syphilis. He was admitted to St. Bartholomew's Hospital on Nov. 26th, 1885, and died Jan. 21st, 1887, having been out for a short period during his illness. He suffered from an irregular fever, for two months had a temperature suggesting quotidian ague, then two months of almost normal temperature, then daily fever for a week, then six weeks of normal temperature, then fever again. He improved under very large doses of quinine, thirty-five grains every twenty-four hours, and his spleen was perceptibly reduced in size. The proportion of white blood-corpuscles to red was throughout about one to five. The history of malarial infection, and the appearance of the liver and spleen, make it certain that the chronic inflammation is that form of cirrhosis due to intermittent fever. The large quantity of caseous material in the glands and the distribution of the white masses over the peritoneum are strong evidence that the white masses in the liver and spleen are true tubercle. Gummata they are not. They resemble of course leukæmic tumours, but their caseous degeneration as well as their distribution seem to negative the hypothesis that they belong to this class. They are tubercles invading viscera already affected by long-lasting changes due to malaria.—Dr. COUPLAND remarked upon the very high degree of leucocytosis present in this case; he would almost have been inclined to regard the case as one of leucocythæmia. Was it usual in malaria to have so large an increase of white corpuscles?—Dr. G. N. PITT thought the association of diseases in this case resembled that seen in hypertrophic cirrhosis of the liver. He had seen several cases in which acute tuberculosis terminated cirrhosis.—Dr. GOODHART thought that a fair proportion of cases of leucocythæmia supervened on malaria. Enlargement of glands or lymphatic leukæmia was often present also, and the complication of tuberculosis was not unknown. He thought these mixed cases were related, and could be traced to malarial poisoning.—Dr. MOORE, in reply to the President, stated that the red corpuscles were normal. He quite admitted the unusual proportion of white corpuscles, but could not explain the appearances on any other hypothesis than that of tuberculosis. He had seen four cases of malaria with leucocytosis, and had seen true tuberculosis supervene upon malaria.

Mr. LAWSON TAIT read a note on the Pathology of Tubal Pregnancy. The views on extra-uterine pregnancy which were first advanced by him at the Obstetrical Society in 1873 were immediately characterised by Dr. John Perry as having at least the merit of simplicity. Many post-mortem examinations and thirty-four clinical cases operated on by him, the remarkable observations of A. Johnstone and Bland Sutton that the inner surface of the uterus and tubes is affected by menstruation, supported these views. He regarded the periodic desquamation and turgescence of the endometrium as essential to the retention of a fertilised ovum, and that is why it is that we have to reckon pregnancies from menstrual dates. He suggested that the starting-point of menstruation—not the cause—lies in the Fallopian tubes. This view is sometimes erroneously called Tait's tubal theory of menstruation. Removal of tubes without the ovaries will in the majority of cases arrest menstruation; the only conclusion is that the tubes have far more to do with menstruation than the ovaries. The ciliary action of the tubal mucous membrane prevents the access of spermatozoa, and aids in the passage of the ovum. The effects of desquamative salpingitis would be to allow the spermatozoa to enter, and would lead to the retention of the ovum in the tube. The tube might thus retain a fertilised ovum and become distended by its growth. Rupture always occurs about the end of the third month. The primitive facts of anatomy explain the rest of the pathology of this interesting displacement. The preparations the author has examined at the time of rupture show that the meso-salpinx is practically obliterated by the separation of its layers, just as the broad ligament is obliterated by the growth of a broad ligament cyst or the occurrence of a broad ligament hæmatocele. The tube inevitably ruptures, and the site of the rupture is the leading feature, not only of the future pathological changes, but of the clinical progress and treatment of the case. The site of the rupture is determined by the seat of the placenta, and if the rupture takes place at any part of the tube covered by peritoneum, extravasation takes place into the peritoneal cavity, forming a tubal intra-peritoneal hæmatocele. If, however, the rupture takes place at a point in relation to the cavity of the broad ligament, the hæmorrhage takes place into the cellular tissue, this fact being alone sufficient to aid materially in arresting the quantity of the hæmorrhage; also into a cavity which is not indefinitely capable of extension. We have in this case the broad ligament pregnancy which formerly was known as the "grossesse sous-peritoneo-pelvienne" of Dezenneris. The relation of the area of the broad ligament site to the seat of rupture which corresponds to the peritoneum makes it certain that the latter will be much more frequent than the former, and clinical evidence establishes this fact. Tubal rupture into the peritoneum will be almost inevitably fatal to the mother, and therefore certainly fatal to the child. Indeed, we have only one indubitable case in which a fatal issue has not taken place, and that is the celebrated case recorded by Jessop, of Leeds. Tubal rupture into the broad ligament, on the contrary, is probably very rarely fatal. The majority of the ova die before they reach maturity; after death takes place they become absorbed. In other cases the ovum dies during the middle months of pregnancy, and it is found after death as a lithopedion, or it may suppurate and discharge above the brim of the pelvis into the bladder or rectum. In a few cases it goes on to maturity; a false labour ensues, in which the child may be removed by abdominal section, an operation in which it is not necessary to open the peritoneal cavity. It will thus be seen that the pathology of extra-uterine pregnancy is made extremely simple by these views, and they explain all the varieties that are known, bringing them absolutely within two categories, and from these pathological facts the rules for surgical proceedings can be very easily laid down.—Mr. DORAN observed that the true pathological question suggested by Mr. Tait's paper was the relation of inflammation of the tube to extra-uterine pregnancy. Disease of the tubal mucous membrane was very common, as the tubal canal communicated with the exterior through the uterus and vagina, and was thus liable to septic infection and to extension of inflammatory affections from the uterus. If, then, this "desquamative salpingitis" rendered the patient liable to tubal pregnancy, that form of pregnancy ought to be very common. Freund's theory that a large proportion of tubal pregnancies ended by early arrest of the development of the fœtus and disappearance of all objective and subjective symptoms would account for the discrepancy suggested by the great frequency of tubal disease and the apparent relative rarity of tubal pregnancy.—Dr. MOORE asked whether there were any specimens in illustration of the paper, and whether the diagram was only a diagram or represented a particular case.—Dr. W. S. A. GRIFFITH thought that, without an examination and criticism of specimens, the evidence in support of Mr. Tait's views was

Digitized by Google

not incontrovertible; the drawings were diagrams, and not representations of facts. In reference to the rupture in tubal pregnancy taking place at the side of the placenta, he reminded Mr. Tait that this structure was not differentiated till after the third month of gestation. He had a month previously brought forward the first recorded case of salpingitis as a cause of extra-uterine fœtation (THE LANCET, p. 268).—Mr. LAWSON TAIT, in reply, said that one of the drawings represented a particular case; the other was a diagrammatic representation of the parts seen in a case he had operated upon. He was glad to hear of Freund's views, as they confirmed the impression he had been arriving at that tubal pregnancy was common. In reference to the placenta question, he was frequently engaged in removing pieces of placenta before the third month of gestation; they were usually infiltrated with blood, hence the difficulty in recognising their real nature.

Mr. R. BARWELL showed a case of (?) Cirsoid Aneurysm of the Left Upper Extremity. The man came for a wound of the left index finger, the bleeding from which was controlled with difficulty by a firm pad under the bent fingers. Gangrene of two fingers commenced after thirty-six hours. The arm was amputated above the elbow after ligaturing the subclavian artery. The veins of the arm and forearm pulsated strongly and with a thrill, but there was no buzzing unless on direct auscultation. The arteries freely pulsated everywhere in the affected limb. There were no discolourations or nævi. There was no hypertrophy, or warts, or overgrowth of hair. The condition was congenital. There was no direct communication between any artery or vein. A venous plexus existed on the median nerve just above the wrist. The venæ comites were not large. The third part of the subclavian ligatured was not enlarged. The brachial and other arteries were greatly enlarged and tortuous. An aneurysmal dilatation was seen at the origin of the superficialis volæ from the radial. There was not that meshwork of mixed arteries and veins as seen in cirsoid aneurysms. It was neither aneurysmal varix nor varicose aneurysm. Macro-anginosis was the term he applied to this unique disease.

Dr. J. A. PRICE showed a specimen of Cholesteatoma at the Base of the Brain, taken from the body of a widow, aged thirty-nine. It was situated in the space extending from the medulla to the optic chiasma, laterally extending as far as the temporo-sphenoidal lobes; it was encapsulated, the capsule being continuous with the pial arachnoid, and the brain substance was everywhere free from new growth. Microscopically, many cholesterine crystals were found in it, besides granular masses, and cells devoid of nuclei; the tumour was very brittle, and of pearly white aspect. There were other similar smaller tumours by its side. The patient had been ailing for five years, and had been liable to seizures, probably of an epileptic character; she had atrophy of both discs, and had been blind with the right eye for four years. A similar case had been fully reported in the fifth volume of the Society's Transactions.

The following card specimens were exhibited:—Mr. D'Arcy Power: A Rhinolith. Mr. Shattock: Colles's Fracture, with Displacement Forward of Lower Fragment. Mr. Doran: Horny Growth from Neck. Dr. G. N. Pitt: Thickened Capsule of Testicle. Dr. A. Withers Green: Aneurysm of Aorta ruptured into Pericardium.

MEDICAL SOCIETY OF LONDON.

Annual General Meeting.—Perforation of Femoral Artery and Vein from Suppurating Bubo.

THE annual general meeting of this Society was held on Monday last at 8 P.M., Mr. R. Brudenell Carter, F.R.C.S., President, in the chair. The President and officers of the Society for the ensuing year were elected. Their names appeared in our columns last week. The report of the Council stated that the Fothergillian gold medal would not be awarded, as only one essay, of insufficient merit, had been received.

Mr. MARMADUKE SHEILD read a case of Perforation of the Femoral Artery and Vein that occurred in a man aged twenty-two, a porter, admitted into Westminster Hospital under the care of Mr. Macnamara. The patient had a chancroid on the penis, phimosis, and a suppurating bubo in the groin, which was opened and profuse and offensive discharge let out. Counter-openings and stimulants were employed, but the suppuration extended. When the case came under Mr. Sheild's care, on Feb. 9th, 1887, the soft parts in the groin were much involved. The sinuses were slit up. One sinus passed behind and internal to the femoral vessels, leading into a cavity. The cavity was sponged out, and then bleeding commenced, slow and venous at first, arterial afterwards. The cavity was laid freely open and compression practised at the groin. Digital compression was successfully tried for a time. Davy's lever was employed to control the hæmorrhage, and both vessels were exposed and the ulceration explored. A hole the size of a crowquill was found in the femoral artery, or a part of the vessel near the trunk of the artery. The artery was tied once by itself and a second time with the vein lower down. The patient was much exhausted, and collapsed. Notwithstanding every attention, the patient remained very ill with pyrexia and rigors, and died a few days after the operation of ligature. At the partial inspection after death the head of the femur was found to be displaced towards the obturator foramen. The ligatured vessels were removed, and the specimen was shown to the Society. The vein between the ligatures was in a sloughy state. The superficial femoral artery was obliterated by firm clot. The author reviewed the literature of these rare cases.

Sir W. MAC CORMAC said the cases were very rare. He gave his own experience of like cases. It did not follow that ligature of both vessels near Poupart's ligament would necessarily lead to gangrene. Stromeyer said that double obstruction was a sufficient indication for amputation of the limb near the trunk. He strongly agreed with Mr. Sheild that pressure was an uncertain method of treatment.

Mr. BERNARD PITTS referred to a case of suppuration above Poupart's ligament in a boy. There was high fever. Aspiration was at first practised. But the fever continued, and abscesses appeared below Poupart's ligament. These abscesses Sir W. Mac Cormac incised, and counter openings were made. A few days later free hæmorrhage occurred, and this was found to proceed from a hole in the anterior aspect of the femoral artery half an inch below Poupart's ligament. In finishing the operation of ligature of the artery a snick was made in the vein, and this necessitated the double ligature of the vein. The boy recovered; the limb did not become gangrenous, was merely cold for a few days, and ultimately became a serviceable limb, though it was a little smaller than the sound one. He advocated powerful cauterisation as the treatment for sloughy wounds.

Mr. PICKERING PICK attempted to explain why it was that the carotid and femoral arteries were the only arteries that were the seats of this form of hæmorrhage. He considered that disease of the superficial glands might lead to affection of the deeply situated glands which are bound down by the strong fascia of the limb. It was possible that this close confinement by a tense fascia had at least some share in causing ulceration of large bloodvessels.

Mr. ASTLEY BLOXAM referred to two cases of hæmorrhage from the groin resulting from suppurating bubo: one occurred in a female and the other in a male. Both died from exhaustion, and in both the femoral artery was ulcerated. He alluded to a case of Mr. Morrant Baker's, in which the gluteal artery was the bleeding vessel, and to one in which the iliac artery opened into the psoas abscess. Pressure would, in his opinion, be valueless; the vessel should be secured where its coats were in a healthy state.

Mr. C. B. LOCKWOOD said that moist gangrene would be very likely to occur after double ligature when the limb was not in a healthy state, as when the ligature was performed for aneurysm or infiltration of the limb with blood.

Mr. THOMAS BRYANT was much pleased with the recital of Mr. Sheild's rare cases. And he could not help thinking that this condition of sloughy ulceration was responsible for the changes about the artery that led to ulceration and hæmorrhage. He had never met with one case of the femoral artery or vein which required the treatment such as Mr. Sheild had adopted. He had had cases of copious hæmorrhage in the inguinal region, all of which had subsided under simple pressure; and yet it was doubtful whether there was not perforation of the large vessels. The diagnosis was the difficulty. The hæmorrhage frequently came from the lower end of the bleeding vessel. Pressure should always be tried first. The axillary vein and internal jugular vein have often been tied without bad results. Some authorities in Germany advocated ligature of the main arterial trunk if the main venous trunk were ligatured.

Digitized by Google

Mr. HARRISON CRIPPS alluded to a paper which he had contributed to the St. Bartholomew's Hospital Reports, 1874, of fifty cases of ligature of the femoral artery in its continuity. He considered that pressure and bandaging, properly applied, was the most appropriate treatment for treating secondary hæmorrhage from the femoral artery. It was important to apply pressure above as well as below the bleeding point.

The PRESIDENT referred to the importance of ligaturing the artery at the bleeding points when ulceration from gunshot wound has been followed by secondary hæmorrhage.

Mr. M. SHEILD, in reply, pointed out that the saphena vein might be patent, and allow of a return of blood from the limb by its communications with the deep and muscular veins.

ACADEMY OF MEDICINE IN IRELAND.

Ovarian Tumour.—Treatment of Vaginismus.—Porro's Operation for Rupture of the Uterus.

AT the meeting of the Obstetrical Section held on Jan. 7th, The PRESIDENT exhibited part of an Ovarian Tumour which had been developed between the layers of the left broad ligament. On opening the abdomen the tumour came into view. It was punctured, and a large quantity of fluid escaped, and then the tumour partly collapsed; but he found it impossible to pull it out. He found that it extended along the uterus to the iliac region, and filled the whole of the broad ligament. It seemed to be unilocular, and therefore he only removed the part of it which he now showed, leaving about a third of the tumour behind. He removed the peritoneal covering and tried removal by enucleation; and in some places it gave way easily enough, but afterwards he came to adhesions which rendered that mode of enucleation impossible. The woman had hardly any rise of temperature until the second or third week after the operation, when she had a slight rise of temperature. She was now apparently quite well.

Dr. MORE MADDEN read a paper on the Treatment of Vaginismus, which he defined as excessive sensibility of the vaginal orifice and adjacent parts, attended with such spasmodic contraction of the sphincter vaginæ as to form an impediment to marital intercourse. This, he believed, occurred chiefly in patients of a hysterical temperament, and was generally occasioned by neuromata, confined to the parts supplied by the superficial perineal branch of the pudic nerve. From clinical experience he could vouch for the possibility, in many cases, of relieving the most intense dyspareunia thus caused, without any operative interference beyond the forcible dilatation of the vaginal canal and stretching the pudic nerve implicated by the disease. The method of effecting this was detailed, and the writer, at the same time, laid stress on the importance of conjoint employment of that topical and general sedative treatment which is indicated in these cases, as in all other local manifestations of constitutional, nervous, or hysterical disorder. In some instances, however, these failed, and we must then fall back on Sims' or Emmet's operations for the cure of vaginismus, the indications for which were referred to. In conclusion, Dr. More Madden pointed out that it sometimes happens that even in cases of vaginismus, so intense as to render complete marital intercourse impossible, the disease is not necessarily a barrier to impregnation. Thus, in one instance under his observation so extreme was the local hyperæsthesia as not only to prevent the possibility of complete cohabitation, but also to prevent the patient submitting to any local treatment for relief of the morbid condition. Nevertheless, conception occurred, and he subsequently was called in to deliver her at full term, and in doing so was obliged to incise the still unruptured hymen by which delivery was obstructed.—Dr. FRASER said he could confirm the remark as to the possibility of pregnancy occurring without vaginal intercourse.—Dr. S. MASON said a little rest, and painting the orifice with nitrate of silver, were sometimes very effectual. It was not always necessary to remove the hymen; but when that operation was done it was always well to make a lateral incision in order to expand the orifice.

Dr. S. MASON read a paper on a case of Rupture of the Uterus. On Nov. 5th, 1886, a patient was admitted to the labour ward of the Coombe Hospital, who had been in labour with her third child for more than three days. Her two previous labours had been difficult and tedious, the child in each case being stillborn, though labour was completed by the natural efforts. A clear history could be obtained of the uterus having ruptured twenty-six hours before the patient's admission to hospital. On opening the abdomen the child was found lying directly behind the abdominal wall, and was easily extracted by traction on the lower extremities; the placenta was in the right lumbar region, surrounded by blood and meconium, and the uterus was situated posteriorly, small, and well contracted, and in its lower part was a tear extending completely through the cervix. The uterus was then removed, the pedicle formed by the cervix being secured by a Keith's clamp and a transfixion needle, the abdomen being closed by silk sutures. The patient rallied well after the operation, and seemed to be progressing favourably for about ten hours, when she suddenly commenced to vomit and died. At the necropsy signs of recent and extensive peritonitis were found in the abdominal cavity. The portion of uterus enclosed in the clamp was torn through to the lower extremity of the anterior lip of the cervix. The bladder was uninjured. The pelvis was that described as the oblique pelvis of Naegele, complicated by projection downwards and forwards of the last lumbar vertebra.—Dr. SMYLY said the great difficulty with which Dr. Mason had had to contend was the poisoning either of the uterus or the peritoneum. To his mind, the great objection to bringing the child back was that it rendered the cleansing of the uterus and perineum impossible if either had become infected. Members were aware that Schroeder had performed Porro's operation in a different kind of case from the present—namely, in order to remove a uterus which had been infected by a portion of the placenta having been left in by the midwife, the doctor not having been sent for until a considerable time after delivery. In that case the portion of the placenta was found to be completely decomposed, and the operation saved the woman's life. Dr. Mason might have lost his patient by performing Sanger's operation instead of that of Porro.

CAMBRIDGE MEDICAL SOCIETY.

A MEETING of this Society was held on Jan. 7th, Dr. J. B. Bradbury, President, in the chair.

Severe Injury to Thorax.—Mr. FRANCIS showed for Mr Sunderland, of Thaxted, a patient who had recovered from a severe crushing injury to the thorax. Three years previously he was crushed between a traction engine and its tender. When seen a few hours afterwards, he was in a condition of great collapse, with considerable hæmoptysis. The sternal end of the left clavicle was dislocated behind the manubrium sterni, and the cartilages of the first six or seven ribs of the left side were separated from their attachment to, or fractured just outside, the sternum, and driven behind that bone. The shoulders were drawn back and confined by a figure-of-eight bandage; but the hæmoptysis continued for a few days, and there was emphysema of the whole of the front, back, and side of the chest on the left side, and irregularity in the heart's action. For several weeks he appeared to be dying; he then improved rapidly, but owing to temporary paralysis of the musculo-spiral nerve on one side, the result of the original accident, he did not resume work until fifteen weeks from the date of the accident. The original deformity remains, and the sternal end of the clavicle can plainly be felt behind the manubrium; there is no evidence of pressure on the trachea, œsophagus, or large vessels.

The Formation of Thrombi in Pulmonary Vessels.—Mr. GRIFFITHS showed specimens of lung illustrative of thrombosis and embolism and the results produced thereby. The first was a specimen of a very large cavity occupying the upper lobe, which extended to the root, where the large branches of the pulmonary vessels were closed by thrombi; the second, where thrombosis had occurred in consequence of incomplete revolution after an attack of pneumonia on the right side, where gangrene in two areas of considerable size had supervened; the third, a series of infarctions of different ages from the same case, in which left cardiac disease and carcinoma of cervix uteri were the chief anatomical lesions. The vessels corresponding to the areas had been dissected to demonstrate the presence of plugs in them. Microscopic preparations of the thrombi and of the different parts of the infarctions were exhibited.

Macro-glossia.—Mr. FRANCIS read the notes of a case of macro-glossia, which had been under the care of [illegible]

Digitized by Google

Humphry in Addenbrooke's Hospital. W. M——, male, aged five months, was admitted on Sept. 1st, 1886. He was thin, pale, and weakly, with a somewhat imbecile expression, but taking notice of things around: the tongue was too large at birth, and had been gradually increasing in size ever since; the child took the breast with difficulty, and had latterly been fed on milk-sop. The mouth was always wide open; the tongue freely protruded, curving abruptly downwards from the tightness of the frænum, with marked drooping and eversion of the lower lip: the protruded part was an inch and a quarter long in the middle line, and an inch and a half broad at the base, and quite symmetrically enlarged in all its dimensions, the edges being thick and rounded, the tip broad, truncate, and slightly bifid. The tongue could just be contained within the mouth, with evident discomfort; there was wide dilatation of the nostrils and marked bulging of the submaxillary region; saliva freely dribbled from the mouth, and there was an eczematous eruption about the chin and lips; the submaxillary glands appeared to be slightly enlarged on both sides. The protruded part of the tongue presented two deep antero-posterior furrows, parallel with the edges of the tongue and meeting just behind the tip; within the furrows the dorsum was convex from before backwards and from side to side, and coated with brown fur. The edges were clean and superficially ulcerated here and there; the papillæ were everywhere enlarged, and scattered thickly and irregularly over the anterior part of the dorsum and to a less extent over the under surface were numerous, pale, translucent, lymphatic cysts, from the size of a millet-seed downwards; the whole tongue was moist, and nowhere cracked or dry. There was no evidence of glossitis, nor hæmorrhages in the mucosa; there were no teeth, no deformity of the lower jaw, no evidence of lymphangiectasis of any description elsewhere, nor any deformities. There was no history of mental disease, or deformities, or struma in the family. The child died suddenly after being in the hospital a week, with a temperature, irregular before, suddenly rising to 108° F. There was a little difficulty in swallowing, but no interference with respiration. A portion of the posterior part of the dorsum, where the disease was least advanced, was examined microscopically. The papillæ were much and irregularly enlarged, more vascular, and covered with a thick layer of cuticular cells superficially. The submucous lymphatics were enlarged here and there, and the lymph canalicular system of the muscle-bundles was especially dilated, but no defined cysts or hæmorrhages were seen.

Mr. WHERRY described and exhibited a case of remarkable Power of Retraction of the Tongue. The organ could be completely pushed up behind the soft palate and uvula, and the tip could be made to touch, with precision, any part of the post-nasal region.

Communication of Diphtheria.—Dr. ANNINGSON described three special epidemics and several isolated cases of diphtheria which had occurred in his experience. The former illustrated very well the tendency of diphtheria poison to cling to localities and reappear at certain periods with special force, as well as the influence of school assemblage in favouring the spread of the disease. One interesting feature was the sudden explosion of the disease, after a period of quiescence, among the girls attending school, while the boys, with one exception, escaped; and his case was explained by his having been exposed out of school hours to the same influence as the girls. Dr. Anningson also related some apparently unexplained cases of diphtheria in lonely detached houses; which afterwards could be traced to rain water used for drinking which had been contaminated by the droppings of domestic birds; also an instance where the converse seemed to have occurred in the infection of pools by human discharges.

ROYAL LONDON OPHTHALMIC HOSPITAL. — The annual general meeting of the supporters of this institution was held on the 8th inst. The report stated that the hospital had in the past year afforded relief to 28,260 persons, the in-patients numbering 2049 and the out-patients 26,211. The total receipts for the year, including legacies, amounted to £6939, a sum which more than met the expenditure.

PRESENTATION.—The Committee of the Monkwearmouth and Southwick Dispensary have presented Dr. Bruce Low with an illuminated address, he having been appointed a surgeon for the Sunderland Infirmary, and consequently having resigned his connexion with the Monkwearmouth institution.

Reviews and Notices of Books.

A Treatise on the Principles and Practice of Medicine. By AUSTIN FLINT, M.D., LL.D. Sixth Edition, revised and largely re-written by the Author, assisted by WILLIAM H. WELCH, M.D., and AUSTIN FLINT, M.D., LL.D. London: J. and A. Churchill. 1886.

A NEW edition of a work of such established reputation as Flint's "Medicine" needs but few words to commend it to notice; but to this sixth edition there attaches a melancholy interest in the fact that its preparation occupied the mind of its learned and much-lamented author during the closing years of his life. It may therefore in truth be said to embody the fruit of his labours in clinical medicine, ripened by the experience of a long life devoted to its pursuit. The volume has further been revised by the author's son, the well-known Professor of Physiology in the Bellevue Hospital Medical College, and by Dr. Welch, Professor of Pathology in the Johns Hopkins University. A comparison of this edition with the preceding, which was published in 1881,[1] serves to illustrate in a striking manner the remarkable advances made, especially in pathology, during the past five years, necessitating in many chapters an entire recasting of the text, with numerous additions in the statements of observed facts. Dr. Welch's assistance in these chapters has been invaluable, with the result that the reader will find a clear and succinct account of our present knowledge upon the etiology of disease and the nature of morbid processes which no other text-book of medicine supplies. Amongst the additions to the volume may be noticed the articles on Infectious Tumours, Syphilitic Disease of the Lungs, Cerebral Syphilis, Spastic Cerebral Paralysis of Children, Hereditary Ataxia, Myxœdema (which, by the way, is omitted from the index), Multiple Neuritis (where, however, we miss any reference to the recent and rapidly accumulating evidence of the influence of alcoholism in its causation), and the General Pathology of Fever; but this enumeration does not nearly cover all the additions and alterations in the text of the work. If we were to single out, where all is of such good quality, any chapters as especially noteworthy, we should have little hesitation in pointing to those upon Diseases of the Lungs and the Heart, for these were subjects to which Dr. Flint paid special attention. His well-known views upon the constitutional nature of pneumonia, or as he terms it "pneumonitis," or preferably "pneumonic fever," promulgated many years ago, have received striking confirmation in Friedländer's discovery of the "pneumococcus," although it is pointed out that the evidence of this being the specific organism is as yet inconclusive. The article on Pulmonary Phthisis is notable for the sagacious remarks upon treatment, especially upon the momentous question which is pressed upon the physician as to advice respecting the patient seeking a change of climate. In the chapter upon Valvular Disease of the Heart the significance of the various murmurs is most clearly set forth. The section devoted to Diseases of the Hæmopoietic Organs contains an excellent account of pernicious anæmia, in connexion with which it may be remarked that "more than twenty-five years ago" Dr. Flint pointed out the dependence of certain fatal cases of anæmia upon degeneration of the gastro-intestinal glands, which Dr. Fenwick in this country confirmed many years subsequently. But it is not necessary to adduce evidence of the care or labour expended on the work; it speaks for itself, and will remain as a permanent testimony to the great abilities of its author. We cannot, however, refrain from quoting a passage from the preface contributed by his son, for it affords

[1] THE LANCET, vol. ii. 1881, p. 134.

Digitized by Google

some insight into his immense industry and capacity for work, that may be taken as an example worthy to be followed:—

"The basis of the work is an unbroken series of records of cases in private practice and in hospitals, begun in 1833 and continued for more than half a century, covering 16,920 folio pages of manuscript, written with the author's own hand. These records embrace carefully written histories of cases in all departments of practical medicine, observed under varied conditions of life, climate, and general surroundings. Soldiers in camp and barracks; the rich and the poor; those affected with diseases incident to lives of ease and luxury, and paupers in hospitals; the pioneers of Western New York and the inhabitants of the metropolis; patients in the wards of the almshouse and hospitals of Buffalo, of the Marine Hospital in Louisville, Kentucky, the great Charity Hospital in New Orleans, Louisiana, the Bellevue Hospital, the Charity Hospital, the dispensaries and similar institutions in the city of New York; cases observed in the experience of a quarter of a century as a general practitioner, and of more than another quarter of a century as a consulting physician, including the epidemics which have occurred in this country within the last fifty years,—the experience derived from these various sources of observation, carefully recorded, studied, and analysed, was finally used in the composition of this treatise, the first edition of which appeared in 1866."

America may well be proud of having produced a man whose indefatigable industry and gifts of genius have done so much to advance medicine; and all English-reading students must be grateful for the work he has left behind him. It has few equals either in point of literary excellence or scientific learning, and no one can fail to study its pages without being struck by the lucidity and accuracy that characterise them. It is qualities such as these which render it so valuable for its purpose, and give it a foremost place among the text-books of this generation.

Anatomy and Physiology in Character. By FURNEAUX JORDAN, F.R.C.S. London: Kegan Paul, Trench, and Co. 1887.

ATTEMPTS to connect physiological appearances with a certain stamp of character are as old as Aristotle and Plato. Mr. Jordan, in his recently published work, seeks to establish the connexion on a scientific basis. In the preface he apologises for the "unpleasant and clumsy epithets of shrewish and non-shrewish," which he uses for want of better terms. His attention some time ago was drawn to the physical conformation of women in hospital suffering from ill-usage at the hands of their husbands. The peculiarities common to them all were a clear skin, often pink, scanty hair growth both on the head and eyebrows, and convexity of the spine, more or less marked. Friends and neighbours said or hinted that these women had "sharp tongues in their heads." Mr. Jordan eventually discovered that these peculiarities in connexion with a shrewish character were not confined to one sex, and he classes men and women under the two heads of "shrews and non-shrews." Some of us may be inclined to doubt the truth of Mr. Jordan's deduction, remembering cases of decided shrewishness in persons of markedly pigmented skin and thick hair growth, and an absence of the same in the type called by him "shrews." After three chapters devoted to the character of the shrew and non-shrew, male and female, there is an account of the differences of skin, hair, and bones to be found in these two classes. In the shrews the dorsal curve is of excessive length, not infrequently reaching even below the waist. This curve affects the position of the head, and throws it forward. "The antero-posterior diameter of the thorax is relatively increased; hence its cavity from breast-bone to spine is deeper. In the non-shrewish skeletons the long transverse is exceedingly marked; it would seem as if the thorax were endeavouring to throw itself back and embrace the spinal column. This backward tendency of the spine has one striking result—the curves of the thorax posteriorly on each side of the spine lie at a level distinctly posterior to the most prominent portions of the vertebral bones, so that, looked at from behind, the spine, even at its dorsal curve, is seen to lie on an actual hollow between the two shoulders." Mr. Jordan lays some stress on the fact that in shrewish men and women the skin is clear, transparent, and pigmentless, often accompanying very pretty features. The nails are inclined to be thin and weak, easily bent or torn, the hair thin and scanty, the eyebrows especially being poor and uneven. That marriages should ever be arranged by a mutual choice of shrews with shrews and non-shrews with non-shrews appears to be very hypothetical; still, Mr. Jordan is not without some hope that future years may bring such a result. The characters of shrews and non-shrews may be summed up in a few words. Shrews are superficial, restless, consequential; having no deep sympathies, affections, passions, or emotions; nearly always moral, not from an inherent sense of duty, but from the desire to be considered respectable. They are apt to be discontented at home, but to shine in society, of which they often form very useful members. Non-shrews cannot precisely be described as the direct antithesis, but they have deep emotions, sympathies, affections, and passions. Non-shrews are more easily led into crime, owing to their deeper feelings. It is not incompatible with non-shrewishness to shine in society or to be voluble and passionate, since a shrewish person does not feel deeply enough to be really angry. Mr. Jordan expresses a hope that more attention will be paid in future years to physiology in connexion with the training of children and the development of character. The closing chapters are devoted to the shrewish character in connexion with literary work and the influence apparent in many standard books.

Alexander Wood, M.D., F.R.C.P.E., &c.: a Sketch of His Life and Work. By the Rev. THOMAS BROWN, F.R.S.E. (his Brother-in-law). Pp. 203. Edinburgh: Macniven. 1886.

To the personal friends of the late Dr. Alexander Wood this book cannot fail to be acceptable as furnishing them with a record of his many kindly and estimable qualities, and of the zealous manner in which he worked to advance the interests of his profession and to promote any public philanthropic and Christian work. It will also prove interesting to many of the older alumni of the university and medical schools, as it contains some reminiscences of Edinburgh as it was sixty years ago, and of the professors and teachers about that period. But we regret to add that it is open to the objection which may be brought against most of the biographies written by near relatives, that it takes a very partial and one-sided view of the work done by the subject of the memoir. A reader of the present volume might fairly rise from its perusal with the impression that almost all the work done in Scotland during the last half-century to improve the science of medicine and the status of the profession had originated with, and been carried through mainly by, Dr. Wood. In fact, there is scarcely, from the beginning to the end of the book, any mention of the work done by any other member of the profession. This is much to be regretted, as it cannot fail to produce an unpleasant impression that his biographer is claiming for him an amount of influence which he did not exercise. Dr. Wood's many good qualities and zealous work were sufficient to ensure him distinction and respect without the labours of others being of necessity ignored. The volume is remarkably well brought out, and contains two portraits of Dr. Wood—in middle life and in his later years.

THE LANCET.

LONDON: SATURDAY, MARCH 12, 1887.

THE Committee appointed to inquire into the accommodation for prisoners in court-houses and other places while waiting for trial at assizes and sessions have now issued their report, and the particulars contained therein confirm in the fullest manner the grave charges which THE LANCET has from time to time brought against the existing arrangements, and proves that, so far from such complaints being exaggerated, as has been repeatedly affirmed, the accusation has actually fallen far short of the reality. Those only whose duty it has been to visit the court-houses and other places where prisoners are detained whilst waiting for trial could have been prepared for the statement of the committee, that "in very few everything that can be expected is to be found," but many, "on the contrary, are as bad as well can be." Of these they go on to say "that nearly every requisite of humanity, and even of common decency, is wanting; and scenes still take place which it might reasonably have been hoped belonged to fifty or a hundred years ago." When the details on which this statement is based become known to the people of England, a feeling of disgust and mistrust will be aroused, which will fall heavily on those who have sturdily maintained the perfectability of our prison system: disgust that such abominations are permitted; mistrust lest the much-praised management of the gaols be in reality as defective as that of the court-houses. With regard to this latter point our opinion has been frequently expressed, and it is well known that we do not view with approbation the treatment indiscriminately adopted for all prisoners after trial under the provisions of the new Prisons Act.

But to return to the arrangements provided for those who are not yet proved guilty. In the first place, one would imagine that, in England at least, there would be neither want of ventilation nor of decent closet and urinal accommodation; yet in Derby we find as many as twenty prisoners at a time crowded into a room only 18 ft. by 9 ft.; at Ipswich, twenty to thirty in a room of 11 ft. 10 in. by 5 ft. 2 in. by 6 ft. 3 in.; and at Oxford, twelve in a room 9 ft. by 8 ft. 6 in. In some of these rooms there is no separation of adults and children, of convicted and unconvicted! In some of the places, however, where separation is attempted, torture is superadded to confinement, and men and women are bolted for many consecutive hours, sometimes days, in dens hardly larger than ordinary clothes-cupboards. Thus at the Central Criminal Court the dens are 2 ft. 6 in. by 3 ft.; at Marlborough, 2 ft. by 2 ft. 4 in.; Gloucester, 2 ft. 1 in. by 2 ft. 4 in. In these last the Committee inform us that prisoners have been confined six days consecutively. As regards the sanitary arrangements, in many cases the offices of nature, if performed at all, must be performed in the presence of spectators; at Hereford there is an earth-closet, without a screen, in the one room occupied by the prisoners and the warders. Happy those who are provided with pails in their cupboards. At Marlborough there is one room with a number of boxes in it. "Sawdust is used to cover the excreta; the stench is sometimes very bad." At Petworth, with sometimes twenty-two prisoners in one room, the only accommodation is a bucket behind a screen. In important towns, such as Carlisle, Derby, Newcastle, and Oxford, there is no watercloset, privy, or accommodation of any sort. After such a confession as to the provisions for ordinary decency, we are not surprised to learn that the arrangements for lighting and heating are extremely defective. Some places are, indeed, provided with hot-water pipes and gas-burners, but in this case the prisoners seem to be worse off than without them, for owing to the minute cubic space allotted in these dens, the atmosphere speedily becomes close and overheated, whilst the heat causes rapid decomposition of the contents of the pails and the sawdust-covered excreta, so that after a few hours the effluvium becomes unbearable and the air foul and poisonous. In other places no attempt is made to warm the buildings, so that in winter the temperature sinks often to 40° F., and that with damp and unprotected stone floors. These insanitary conditions explain in part the high relative death-rate from pneumonia, which we have often pointed out as characteristic of prison bills of mortality, though no doubt the plank bed and deficient dietary of the convicted prisoner give the final stroke. In some places the gaslight is placed outside the cell, so that the prisoner remains in partial darkness and gloom, sometimes for many days together. Even in these wretched holes one would think some provision would be made for the physical rest of the prisoners, yet we learn that in the prisons where seats are provided they are mostly of stone and brick, cold and damp, and consequently injurious if used continuously; but in most instances no seats are provided, and the wretched prisoners have either to stand like cattle in railway trucks, or squat like negroes between the decks of a slaver. So much for the physical aspect, but the moral is quite as revolting; one would think the matter of the separation of the sexes is a question that would hardly be open for discussion, and yet "this elementary requisite of decency" is not invariably provided for. We always understood that the separation of prisoners was one of the most important points attended to under our "perfected" criminal laws. Fancy the fate of a young servant girl, arrested on suspicion for some small theft—erroneously, perhaps,—kept in contact for many hours with abandoned men and women. Lucky for her if chance isolates her in the two-foot cupboard! Surely the reasons that separate tried prisoners from each other hold with greater force in the case of the unconvicted.

Only a few years have passed since THE LANCET commented upon the treatment of an unfortunate unconvicted prisoner who died at Winchester, after repeated journeys to and from Southampton, where he was exposed to many of the evils at present commented on. At the time we were assured that our statements were unwarranted, and our conclusions false; but the present picture is a hundredfold darker than we then dared to think even possible. Then the officials declared that the arrangements were perfect; now it is clearly shown how defective in many cases they really are. As it has been proved with regard to our court-houses, so we

Digitized by Google

fear it is with our gaols. We have had repeatedly to comment on the deaths of prisoners in gaol from pneumonia or suicide, and other causes, and we are repeatedly told that these are exceptions—that no system was ever more perfect. We doubt it, even as we doubted the case of the unconvicted, and we hope the public and the press of England will call for a commission of inquiry into the conditions of convicted similar to that which has just issued its report on the treatment of unconvicted prisoners.

WE have already dealt at length with that portion of Dr. BUCHANAN'S recent report which discusses the important question of the influence of small-pox hospitals in London. It remains to note some of the other subjects which are dealt with in the same volume. Amongst these the connexion of scarlatina with disease in milch cows is referred to, the points discussed being mainly based on the circumstances attending the Hendon scarlatina epidemic in 1885, although the whole story of milk epidemics is briefly alluded to. The Hendon outbreak, and the reports on it by Mr. POWER, Dr. KLEIN, and Dr. CAMERON, were commented on in our columns at the time of the occurrence, and we need now only refer to the matter in connexion with the more recent labours of Dr. KLEIN as to the pathology of the illness in the cow, which was found to be associated with the scarlatina, and to point out that his completed report is illustrated by a series of excellent lithographic plates. It must also be noticed that, amongst other important observations recently made on this matter, Dr. KLEIN is announced to have obtained from the blood of ordinary human scarlatina a micro-organism identical in its morphological characters with that inhabiting the ulcers of the Hendon cow disease. In view of what has recently been learnt as to scarlatina, Dr. BUCHANAN finds reason to expect that a measure of additional control may be obtained over a disease which, in spite of the general sanitary progress of the country, is still fatal to some 17,000 or 18,000 persons during the average year in England and Wales. Dr. KLEIN has also pursued his investigations as to foot-and-mouth disease, and he has been able to identify the disease in the lower animals with a definite kind of micrococcus occurring in wavy chains, streptococcus, in the vesicles of the disease; and subcultures have the power of inducing the same affection. This power is most surely exerted when animals are fed with the infective matter, but although inoculation does not produce disturbance of health, yet animals so inoculated became refractory to the influence of the poison administered to them by feeding.

Tubercle has been further studied by Dr. KLEIN and Mr. LINGARD, and, in addition to some negative results, it has been ascertained that tubercle in the fowl, which is of the nature rather of the disease which affects man than of that which prevails in bovine animals, can be communicated to the fowl during feeding by means of human tubercular sputa. Further, it appears that tubercle derived from the human subject, and used to produce disease in fowls, may undergo some loss of its infective power during its passage through the fowl.

The important subject of disinfection has continued to engage the attention of the medical department of the Local Government Board, and further investigations have been carried out by Drs. KLEIN and CASH as to the influence of perchloride of mercury. Both the antiseptic or restraining powers of this salt and its disinfecting or killing powers are now ascertained to be considerably greater than those of any other known substance. Dr. KLEIN states that non-pathogenic substances offer the greatest resistance to the operation of the mercuric salt, and he describes the measures by which it is practicable to produce a modified form of anthrax in sheep by inoculating the animals with the material of anthrax along with corrosive sublimate, and this without the special aid of experts. The drug, according to Dr. CASH, appears to operate in a way similar to that of a previous attack of the disease, giving, for a time at least, a feebler quality to an attack of the disease, and this in turn seems to give immunity against recurrence.

The report contains a further contribution from Dr. DUPRÉ on the question of the consumption by bacteria of oxygen from the dissolved air in water. Dr. DUPRÉ has had to differentiate between those organisms which are and those which are not destroyed by prolonged heating to a temperature of 60° C.; and, experimenting with London waters, the following results, as summarised by Dr. BUCHANAN, have been arrived at. 1. Differences are observed at different periods of the year in the behaviour towards oxygen of the bacteria of the water furnished by a London company deriving its supply from the Thames; differences which seem to require for their explanation that there is variation in the power of different bacteria (present at one and another time) to resist a temperature of 60° C., or else that there are seasonal fluctuations in the power of the surviving bacteria to use the oxygen of water-dissolved air; differences which, it is to be observed, would not be in any way discerned by ordinary chemical methods. 2. The faculty of consuming oxygen, after resisting a temperature of 60° C., possessed by waters taken from the Thames and Lea, and attributed to the bacteria contained in them, is present in a higher degree in deep well waters; their special faculty, again, varying at one and another time, as in the case of the Thames water. This latter consideration leads Dr. BUCHANAN to point to the possibility that we may here be confronted with the existence in deep well water of unrecognised spores of bacteria, and with the question of the influence of light on bacterial life. Indeed, the research tends to show how much we stand in need of knowledge as to harmless as well as to disease-producing bacteria. In fact, the whole subject naturally calls forth a plea for the further study of bacterial life, and Dr. BUCHANAN urges that instead of dealing with the harmful bacterium, when detected, as we now do by poison or by boiling, we may find it more scientific to turn against it such forces of nature as are customarily antagonistic to it. The whole history of bacteriology and of epidemic disease points to the existence of such forces, and pathologists have long been inclined to believe that amongst "agencies antagonistic to the bacteria of disease, none will be found to equal in potency the agency of other bacteria." Holding such points in view, Dr. BUCHANAN, whilst promising in the immediate future further inquiries into the pathology of scarlatina and into other matters of immediate urgency, expresses a hope that opportunity may be afforded for some more general

Digitized by Google

researches into the important subject of the life-history of bacterial organisms. There are reasons for believing that in such study a clue may be found to much that is still mysterious and unintelligible in connexion with epidemic disease, and no more fitting work than that suggested could be undertaken by that department of the Government which is above all others, interested in controlling those influences which tend to injure public health.

THE Oldham poisoning case is remarkable in many ways, and is well deserving an analysis. The facts which transpired at the Liverpool Assizes just concluded, where on Feb. 25th the prisoner was convicted and sentenced to death, are briefly as follows. The prisoner, ELIZABETH BERRY, aged thirty-one, was a nurse at the Oldham workhouse infirmary. She was a widow, with one child aged nine years and six months. She was indicted for having wilfully murdered this child by administering to her a corrosive poison. The deceased girl had been living for some years with a sister-in-law of the prisoner, who paid certain sums for her maintenance, clothing, &c., in all between £12 and £13 per year. On Dec. 27th, 1886, the prisoner visited her daughter at Miles Platting, and returned to Oldham with her and a child companion on Dec. 29th. The deceased remained well in health up to the morning of Jan. 1st, 1887. The sitting-room of the prisoner was next to the dispensary of the infirmary, and she alone had the key of the dispensary. At 9.30 A.M. on the aforesaid day deceased was running about with her playfellow; at 10.15 A.M. she was in the dispensary, accompanied by no one except her mother; fifteen minutes later she was seen vomiting in the sitting-room. The prisoner was holding a tumbler in her hand, and the deceased was heard to exclaim, "Oh, mamma, I can't drink it." The vomited matter was thrown away at the request of the prisoner. Dr. PATTERSON, the infirmary medical officer, was asked to see the child. He prescribed iron and cinchona. A vessel was shown him in which was some matter streaked with blood. He seems to have suspected that the child's illness might not have been due to natural causes, but this suspicion he evidently did not consider sufficiently grounded to act upon.

The prisoner would have no one to sit up with deceased but herself. Curiously no explanation of her illness seems to have been given by or sought from deceased. Next morning (Jan. 2nd) the patient was better—so much so that Dr. PATTERSON expressed himself as hopeful of her recovery. Towards evening, however, she became much worse, and Dr. PATTERSON was again sent for. His attention was directed to a "towel covered with matter which contained blood." Feeling dissatisfied, he asked Dr. ROBERTSON to meet him in consultation. As the result of this, morphia and bismuth were prescribed to combat the symptoms—vomiting and pain at the stomach. On the same day (Jan. 2nd) redness and, according to one witness, blistering of the lips were observed. It is certain a blister had formed by the morning of the third day. The symptoms noted above continued more or less pronounced until death, which occurred from exhaustion at 5 A.M. on Jan. 4th. During life Dr. ROBERTSON noticed that the lips, gums, and tongue were white, but moist. The whi was not from furring, for, as Dr. ROBERTSON testified, he had never seen a tongue like it before.

The prisoner gave two explanations of the marks on the lips: (1) that they were caused by some lemon and sugar, and (2) that they were due to the "ulceration of the mouth." Post mortem these marks became dry and brown, and were clearly owing to the action of some powerful irritant or corrosive. The outline of the marks on the lip, extending on either side from the middle to the angle of the mouth, and in one place for three-quarters of an inch on the cutaneous surface, was quite inconsistent with the theory of *herpes labialis* suggested by the counsel for the defence. In addition to the state of the lips and mouth just described, other evidence of corrosion was forthcoming at the necropsy. In the œsophagus was a black charred patch, and there were black streaks below this. The stomach was not charred, but it showed signs of recent inflammation, and so did the small intestine. With the exception of an old caseous nodule found in one lung, there was no organic natural disease. The contention that the deceased was tubercular had thus no foundation in fact. The weakness of the defence was shown by challenging the view taken by Drs. HARRIS PATTERSON, and ROBERTSON, and Mr. ESTCOURT—viz., that the tissues had been acted on by some corrosive agent. This was futile in the extreme, for the evidence on that head was overwhelming. There seems no reason to doubt that something was taken by, or administered to, the deceased at the time she went into the dispensary. Had she taken anything accidentally or mischievously, would she not have confessed the fact when seized with obstinate vomiting and acute pain? The lull in the symptoms on the second day might have been deceptive and accounted for by the state of exhaustion; but, considering that the blisters on the lips were not observed until the end of the second day, it seems probable that a second dose of the poison was given. It was hinted in cross-examination that the creasote, or the iron and cinchona mixture ordered by Dr. PATTERSON, might explain the brown marking on the lip; but allowing for one moment this visionary hypothesis, the main question was still unanswered: What was the cause of the antecedent symptoms which set in with such fatal rapidity and violence? It is easy to invent several theories to explain certain isolated sets of facts, but in the case under consideration some theory was needed to cover a continuous chain of circumstantial evidence, and we maintain that the only tenable theory was that embodied in the finding of the jury.

Many statements made by the prisoner were known to be untrue. She averred that the life of deceased was not insured, when it was proved that she had herself taken out a policy for £10, which was paid to her after her daughter's death. Further, she had applied for a mutual insurance policy for £100, and although the company had not acceded to her request the prisoner was not aware of the refusal. Again, she tried to explain the disturbance of the alimentary canal in deceased by falsely saying that she suffered from constipation and had been treated for it. On no ethical standard—legal, religious, or social—could a motive be based at all adequate to such a crime as that which the prisoner was charged with having committed; but history shows that the motive to ill-doing is rarely commensurate with the

Digitized by Google

deed. At the Durham Lent Assizes, 1873, MARY ANN COTTON was found guilty of murder of a stepchild. Afterwards facts transpired which made it all but certain that she had compassed the death of her mother, fifteen children, three husbands, and a lodger—and mainly, if not entirely, for the sake of getting small sums from burial insurance societies. Later still a similar tragedy happened at Liverpool. There was nothing, then, as regards motive inconsistent with the likelihood of guilt in ELIZABETH BERRY'S case.

There is still some doubt as to the nature of the corrosive employed by BERRY; for on chemical analysis of the stomach, intestines, and other parts no poison was discovered, either organic or inorganic. The prevailing opinion points to sulphuric acid. If this be correct, we imagine the acid must have been diluted, or some traces would have been found, in the form of corrosion of the floor, carpet, towels, &c., in the room which deceased occupied during her illness. So far as the presence of soddening of the mucous membrane of the mouth and charring of the gullet and the absence of corrosion of the stomach are concerned, there is no bar to the supposition that sulphuric acid had been given in the concentrated form. It is the exception for the mouth to be charred, and not rarely the œsophagus looks pale, shrivelled, and corrugated, even when there is extensive blackening and perforation of the stomach. The local patch of corrosion in the œsophagus in this case was probably owing to the sudden arrest at that spot by contraction of the circular muscular layer just below. Some may then have passed on to the stomach, and some returned by vomiting. Sulphuric acid, even when considerably diluted, may prove quickly fatal. A man took on an empty stomach six drachms mixed with eighteen drachms of water, and died in two hours and a half (TAYLOR). The emptiness or fulness of the stomach, the degree of dilution of the acid, and the rapidity with which it passes over the mucous membrane, are conditions which greatly affect the extent of corrosion and the violence of the symptoms.

Sentence of death was passed upon the prisoner on Feb. 25th. Three days later a coroner's jury sitting at Castleton to inquire into the death of Mrs. FINLAY (mother of the convict), who died a year ago, returned a verdict of "Wilful murder" against ELIZABETH BERRY. Mrs. FINLAY was seized with attacks of "convulsions and delirium, ending in coma," and the medical man who attended her gave a certificate to the effect that the deceased died from apoplexy. No post-mortem was made at the time. During the illness BERRY was noticed to examine her mother's eyes. After the death BERRY received nearly £100 from an insurance society, and £13 4*s.* from a burial club. A person who gave her name as "ELLEN SAUNDERS," procured a quantity of atropine a short time prior to the death of Mrs. FINLAY, and it was alleged that BERRY was that person. The body of Mrs. FINLAY having been exhumed, an examination was made by Drs. HARRIS and PAUL, and an analysis of the viscera by the latter gentleman, who found traces of an alkaloid which he believed to be atropine judging from its physiological effects. The detection of atropine in a body that had been buried for a year is an interesting and unique event. There seems some doubt, however, whether the substance discovered by Dr. PAUL may not have been of the nature of a ptomaine or cadaveric alkaloid.

DR. LUCAS-CHAMPIONNIÈRE contributes the first paper in the January number of the *Revue de Chirurgie*, and in it he speaks of his experience of the operation of excision of the knee. His results have been so good, and his opinions are so opposed to some current surgical notions, that we desire to call special attention to them. He speaks of the earlier results of this operation as so discouraging that he was not tempted to perform it until 1883, the time when he had come to entertain absolute confidence in the aseptic treatment of wounds. And he lays special stress upon this fact. His opinions and conclusions do not apply to excisions of the knee in general, but only to aseptic operations, in which not only is the risk of blood poisoning entirely abolished, but the occurrence of suppuration prevented. The presence of suppuration he regards as evidence of failure in the operation, and, unless extremely limited in amount, as an imperative indication for amputation. It is clearly essential to realise Dr. LUCAS-CHAMPIONNIÈRE'S position in this respect before dealing with his results and recommendations. His series of cases includes eleven in whom the age varied from seventeen to thirty-four; the disease was tubercular arthritis in all but one case—that of a man, fifty-four years of age, who was suffering from rheumatoid arthritis. All the patients recovered; in nine there was union without any suppuration, in one there was very limited and transient suppuration, and in one case the suppuration necessitated amputation. In no case was there any local recurrence of the disease, and some of the patients were able to walk one or two months after the operation. Such results are extremely good, and cannot fail to excite the envy of most surgeons who have had a considerable experience of this operation. In view of the serious interference with the growth of the limb, the operation is not recommended in children; but, on the other hand, Dr. LUCAS-CHAMPIONNIÈRE thinks that middle-aged adults are suitable subjects for it, provided that the wound be kept aseptic and free from suppuration. He makes some important remarks in reference to tubercular disease. First of all, he has not found that excision of the knee leads to general tubercular infection, and furthermore he does not regard tubercular disease of the lungs as a necessary bar to the operation. Where the pulmonary disease is far advanced, of course no one would entertain the operation; but where the disease in the lungs is in its first or second stage only, he has found removal of a diseased knee-joint exert a distinctly beneficial influence, and lead to a subsidence of the chest trouble. He explains the discrepancy between this opinion and that more generally held by saying that the key to success in this class of cases is the prevention of suppuration. Where the wound heals entirely by primary union, the operation exerts only a good influence upon the lung mischief; but if the wound becomes septic and suppurates, this further drain upon the system shows its presence by the gradual failing of the patient's powers and a more rapid advance of the disease in the lungs.

As to the mode of operation there is not much to say. Dr. LUCAS-CHAMPIONNIÈRE prefers the transverse incision below the patella. He makes the excision very free; always

Digitized by Google

removes the patella and every suspicious portion of femur or tibia; and then, having done this, he, with the most patient care, searches for and removes every particle of "granulation tissue." He drains the wound by three tubes, one at each end of the incision and one from the back of the joint out through the ham. All the ligamentous structures that have been divided, as well as the bones, are united by buried sutures of catgut.

This paper would appear to be an important contribution, and it is another proof of the revolution in surgical opinion and practice that the antiseptic treatment of wounds has brought about. For that is the central fact: upon the possibility of getting complete primary union of the wound hangs all the rest.

WITHIN a few days of the termination of the sittings of the General Medical Council a volume has been issued containing the confirmed Minutes of the Session,[1] as well as the various reports presented to the Council. The latter especially will be read with much interest, for they relate to questions which intimately concern the future of the profession and its usefulness to the public.

The chief of these in point of importance is undoubtedly the final report of the Visitation of Examinations Committee, which shows in every paragraph the extreme care which has been taken to consider the details of professional education and examination. The Committee are evidently impressed with the need for the introduction of practical teaching in every branch which is included in the medical course. The question of the relative values of systematic teaching by lectures and demonstrations and of practical training by the performance of individual work is seriously considered, and the fact is noted that to a large extent lectures have been replaced by more practical methods of teaching. The Committee, however, believe that lectures cannot altogether be superseded, and although text-books give opportunity for students to obtain information outside the class-room, the lecturer should be able to present material of so much value to his pupils, and arranged in such a form, as to render this method of teaching still an important element in medical education. No doubt there are many students whose power of acquiring knowledge is dependent rather upon the eye than upon the ear; a well-arranged course should, however, appeal to both, and the personal qualities of the teacher will go far to create interest in a subject which would otherwise prove tedious, however clearly it might be described in the many text-books which are now written for the students' use.

The period of time which should be devoted to medical and surgical education before the student is permitted to present himself for examination is touched upon in the report. It must be admitted that there is some ground for the argument that the specification of any period is tantamount to an admission that examinations cannot entirely be trusted to adequately test the state of a candidate's knowledge. The Committee, however, evidently regard this requirement as important in the student's interest, as well as of those who will subsequently come under his care, for they give as their reasons for not extending the time to be devoted to medical education the fact that a large proportion of students already voluntarily prolong their studies during five and even six years.

The necessity is recognised for the better teaching of pathology, including mainly pathological anatomy; of therapeutics, considered essentially as comprising the action of remedies on the healthy body; and of hygiene, embracing public as well as private health. These, it is said, are three expanding subjects, and demand special attention and separate teaching. Such recommendations will doubtless be carried out by the majority of the medical schools, and due regard will be had to the comments on the advantages of class examinations and of clinical teaching to classes of limited numbers of students which are embodied in the report. The subject of obtaining practical knowledge by the holding of dresserships and clerkships is given due prominence, but this will also engage the attention of the Committee to which Dr. GLOVER'S motion was referred.

It is impossible to pass from the report without referring to the admirable service which is rendered by the Registrar (Mr. W. J. C. MILLER, B.A.), both to the Medical Council and to the profession, by thus promptly making available for general use the lessons which the report contains, and which especially deserve the earnest attention of all engaged in the important duty of professional teaching and examining.

Annotations.

"Ne quid nimis."

THE SANITARY CONDITION OF WINDSOR.

THE action which the Town Council of Windsor have taken, upon the report of Dr. Hubert Airy and Mr. Arnold Taylor on the sanitary condition of New Windsor, will, we trust, lead to reforms which have been often advocated in the columns of THE LANCET. A meeting was immediately called by the Mayor, and the report was read and carefully considered. The clerk, the medical officer of health, and the borough surveyor were requested to advise them as to what steps might be taken to improve the condition of South-place, and as to the powers conferred by the Public Health Act of 1875 and the Artisans and Labourers' Dwellings Acts, which would enable them to deal with the matters mentioned in the report. A committee was also appointed to consider and report upon the duties of an inspector of nuisances, and it was decided to make inquiry if the guardians of the Windsor Union would unite with the New Windsor Sanitary Authority in the erection of a hospital for infectious diseases and the provision of a disinfecting chamber. The Street Committee were also requested to consider and report on the recommendation that a furnace should be provided for the destruction of house refuse. No time has therefore been lost in taking preliminary steps to giving effect to the recommendations of the Inspectors, and it may be anticipated that under the guidance of Mr. Simpson, the present Mayor, who has a high reputation for public spirit, Windsor will soon attain the position which should be held by the Royal borough. It will be specially interesting to observe the effects of the changes which we hope to see made on the rates of mortality of New Windsor. Dr. Casey has well pointed out that, although these cannot be regarded as excessive—indeed, in some respects are distinctly low,—this is due to the fact of the comparatively small proportion of young and old persons in the population of the town. It is probable that a reduction can still be effected, and this is more likely to take place if steps are

Digitized by Google

taken for preventing the inundation of the low-lying parts at times of overflow of the river. Windsor must not be surprised if England expects her not to rest content with being superior as regards health conditions to some other towns in the country; she must, indeed, strive to be not inferior to the best; history marks her place in our national records, and she should be representative of everything that is best in English life. That she will become so there is now every prospect, and it may be remembered that the conditions which affect health are not limited in their result upon the body alone. The promptitude with which the Town Council are proceeding to carry out their promise to the President of the Local Government Board proves that there is every desire to make the town worthy to be a residence of our Queen.

MEMORIAL OF LONDON SURGEONS TO THE COUNCIL OF THE COLLEGE OF SURGEONS.

WE print in another page an important memorial which has been presented to the Council of the College of Surgeons by the teachers of surgery connected with the metropolitan hospitals. The signatures attached to it include, with only two exceptions, the names of all the surgeons at these institutions who do not occupy seats on the Council. The memorial contains a courteous but earnest appeal for the establishment of a pathological and surgical laboratory in connexion with the Hunterian Museum. Such an institution would be in complete harmony with Hunter's work, and would render the museum a more complete memorial of the founder of scientific surgery. But—and this is of more importance—it would supply a great and pressing need, and would do much to remove the necessity which undoubtedly exists at present of looking to Germany for nearly all advances in those departments of science upon which surgery depends. It is impossible for the Council to ignore so influential a memorial as this, even if it had the will to do so. It is almost equally hard for it to return a *non possumus* to such a request. The fact that the men who are busily engaged in the teaching and practice of surgery have with practical unanimity joined in this request is both evidence of the need that exists and is felt to exist, and a guarantee of the response that would be made to any action of the Council on the proposed lines. We are aware that the funds at the disposal of the College are by no means inexhaustible, and that special difficulties may be encountered before such a laboratory as is asked for could be established on a thoroughly satisfactory footing. But we trust that the Council will do its utmost to meet the very reasonable request now made to them.

THE ANTISEPTIC VALUE OF IODOFORM.

IT was hardly to be expected that the experiments and statements founded thereon which threw doubt upon the antiseptic property of iodoform (see THE LANCET, *ante* p. 328), recently published by Drs. Heyn and Rovsing, would have passed unchallenged. They were promptly and somewhat contemptuously dismissed as untrustworthy by a writer in the *Wiener Med. Wochenschrift* (No. 6); and in the current number of the *Fortschritte der Medicin*, the editor, Dr. Friedländer, warmly defends his contributors against this onslaught. The attack threw doubt upon the experiments as coming from unknown observers, and suggested that the paper had gained entrance to the pages of the *Fortschritte* through editorial inadvertence. Dr. Friedländer has no difficulty in dispelling this idea as being utterly baseless, for not only was the article communicated to him by Dr. Salomonsen of Copenhagen, but he had himself been struck with its thoroughly scientific character and value, as proving at least that iodoform belongs to a class of antiseptics differing from carbolic acid and corrosive sublimate. That the subject deserves further study he freely admits, and carries this out by inserting in his journal a criticism of the paper by Dr. Poten of Hanover, written in a far different spirit from that of the Vienna writers. Dr. Poten points out that the virtues of iodoform as a dressing depend largely upon the liberation of iodine in contact with the tissues and secretions, and also that owing to its insolubility it is not possible to test its action on pathogenic organisms in the same way as other substances can be tested. He does not endorse the statement that iodoform is dangerous because of its possibly being contaminated with septic material, and considers the united testimony of practical surgeons as to its efficacy to override such rather problematical risks.

SIR MICHAEL HICKS BEACH.

THE health of our statesmen is a matter of supreme interest to the public, especially if there be any suspicion that it is affected by their public duties. Some months back Dr. Robson Roose, finding that Sir Michael Hicks Beach was suffering from cataract, suggested a consultation with Mr. Anderson Critchett. It was then found that the sight of the right eye was of little value owing to the density of the lenticular opacity; but as with suitable glasses Sir Michael could still, though with some difficulty, conduct the work of his high official position, he was allowed to continue his labours. Within the last few weeks the sight has rather rapidly declined, doubtless owing to constitutional causes; and at the consultation held on Friday, the 4th inst., at Sir William Jenner's, it was decided that Sir Michael could no longer retain office without grave risk. The cataract in the right eye is diffused, and that in the left eye is now confined to the centre of the lens. Sir Michael will shortly visit Germany for the benefit of his health, and, as it is essential that his case should be under medical supervision, he will while there be under the care of Dr. Pagenstecher, of Wiesbaden. Some little time must of necessity elapse before Sir Michael returns to England to place himself in Mr. Critchett's hands for operation. The hope that this procedure may be successful will be shared widely by the public, who have not been insensible to the unselfish patriotism with which Sir Michael undertook his thankless office, and the devotion to duty which has exhausted his powers.

NEW INSTRUCTIONS TO PUBLIC VACCINATORS.

THE Local Government Board have issued new instructions to public vaccinators, to supersede those of sixteen years ago. The alterations, which are wisely conceived, relate specially to ensuring the better performance of the operation of vaccination, and to the avoidance of septic poisoning. For the former, it is ordered that the insertions of lymph shall be such that the total area of vesiculation on the same day in the week following the vaccination should be not less than half a square inch; for the latter, a caution is given against the use of any means of protection or "shield" that cannot readily be destroyed and replaced whenever it becomes soiled. Public vaccinators are also required to enter in their register the initials of the person operating, and subsequently inspecting the vaccination, and they are cautioned against the employment of lymph supplied by any person who does not keep exact record of its source. It is further required that lymph be not taken from children who have any sort of sore at or about the anus, or from a vesicle around which there is any conspicuous commencement of areola. The caution contained in the superseded instructions not to take under ordinary circumstances more lymph than will suffice for the immediate vaccination of five subjects, or for the charging of seven ivory points, or for the filling of three capillary

Digitized by Google

tubes from such a vesicle as vaccination by puncture commonly produces, is now replaced by the requirement that more than this amount of lymph shall not be taken from a well-formed vesicle of ordinary size except under circumstances of necessity. Lymph, moreover, is not to be taken that has run down the skin, the vesicle is not to be scraped, and the lymph is to be changed if on the day week after vaccination the cases show any conspicuous areolæ round their vesicles, while formerly the presence of any areola was regarded as reason for omitting to take lymph from such a vesicle. Vaccinating lancets are not to be used for any other purpose whatever, superseding the old instructions, which required that they should not be used for other surgical operations. The instructions end with the advice which experience has shown to be necessary: "Never use any ivory point or capillary tube a second time, either for the conveyance or storage of lymph; but when points or tubes have once been charged with lymph and put to their proper use, do not fail to break or otherwise destroy them."

THE SIGNIFICANCE OF THE RETENTION OF THE MEMBRANES AFTER LABOUR.

THE importance to be attached to the retention in the uterus of portions of membrane after the completion of the third stage of labour has been variously estimated by different obstetricians: some—e. g., Winkel, Dorn, Ahlfeld, and Graefe—holding that grave dangers are to be apprehended when this occurs; while others—as Alshausen, Credé, Fischer, and Cohn (who has reported two cases in which nearly the whole membrane had been retained for five days without causing any pyrexia)—believe that little or no danger of hæmorrhage, septicæmia, or other puerperal mischief is caused by the retention of even considerable portions of the membrane. An explanation of this divergence of view has recently been attempted by Professor Lazarevich in the opening article of the new Russian *Obstetrical and Gynæcological Journal*. His explanation is founded on the fact, unrecognised by most obstetricians, that "the membranes," even at the full term, are composed of and more or less separable into three distinct layers representing the chorion, the decidua, and the amnion. The strength of these has been investigated by Poppel, Duncan, and Ribemont, and the amnion shown by them to be much tougher than the chorion in conjunction with the decidua. Professor Lazarevich has also made a number of researches on the subject by means of an apparatus consisting of two rings covered with indiarubber, between which the membrane to be examined was stretched, the resisting force being estimated by means of a wooden hemisphere on which weights were placed, which the membrane was made to support, more weights being added until it gave way. These observations showed that the integrity of the ovum depends almost entirely on the amnion. During labour some separation of the membranes from one another usually occurs, and this is especially the case when the chorion, split or torn below, maintains a close connexion with the decidua, and the decidua with the uterine wall; the progress of the labour also separates the amnion from the chorion. Roemer explains the separation of the membranes from one another by their unequal elasticity, and Professor Lazarevich believes that the chorion, being less elastic as well as more easily torn than the amnion, is frequently ruptured in several different places, some portions coming away attached to the amnion, and some being left behind attached to the uterus. The causes of retention of the chorion with the decidua are: (1) the presence of villi on the chorion; (2) extravasation of blood on the decidua, with consequent formation of fibrous adhesions; and (3) adhesions in consequence of endometritis and choriitis. The amnion may be retained in consequence of—(1) occasionally occurring adhesions between it and the chorion and decidua; (2) early rupture and escape of all or part of the liquor amnii; (3) a low attachment of the placenta or placenta prævia; (4) intra-uterine manipulation; (5) anteversion of the uterus after the birth of the child; (6) exceptional weakness or thinness of the amnion. Retention of the decidua (which is formed from the uterine mucous membrane, not from the ovum) is as a rule of little moment, though it is perfectly possible for endometritis decidualis to occur, and for the retained portions of the decidua to serve for the development of micro-organisms introduced from without. Shreds of the chorion, if retained either by themselves or together with the decidua, do little harm, as they rapidly undergo chemical and mechanical destruction, and are carried away with the lochia. The amnion, when retained, is much more liable to become the developing ground for bacteria, and it is to the retention of this part of the membranes that alarming symptoms are usually due. Professor Lazarevich lays considerable stress on the importance of straightening or replacing the uterus in its proper position after the birth of the child, before the after-birth comes away.

THE JUBILEE AND LONDON HOSPITALS.

WITH the exception of one or two schemes for commemorating the Jubilee of Her Majesty which it is understood have her special favour, there is no other suggestion more popular or more worthy of support than that the moneys raised should be devoted to the relief and support of the great hospitals, which constitute the home of the working classes when afflicted and disabled by illness or accident. This proposal has had our steady and earnest support. It would indeed be a Jubilee to be remembered till a similar Jubilee should occur if these institutions could be relieved of the incubus of debt which depresses them and hampers their operations. The schemes specially favoured by the Queen should be supported for their own sake and out of respect to Her Majesty's wishes. But the public must not forget one claim which, above all others, should command their practical sympathy—the claim of the great hospitals, which now languish for want of money, and whole wards of which have to be closed. The rich and the poor alike admit their indebtedness to these institutions. We can only hope that attention may be concentrated on this subject. The Jubilee is a great and august occasion; it will commemorate much, and will, we trust, be productive of real and permanent benefit. But it is weakened by multiplying modes of commemoration, and by fantastic ones. On this proposal—to free the great hospitals of debt—we are on a rock, and on this rock we would rest the Jubilee Fund. Her Majesty has not so far felt at liberty to indicate her special support of it, but her sympathetic nature is too strong to allow us to doubt that any object could be more satisfactory to her than the welfare of our hospitals.

DRUNKENNESS IN 1886.

THE report just published of the number of arrests made on Sundays for drunkenness in the year ending Sept. 29th last affords some ground for congratulation on the improvement in this respect which is undoubtedly taking place in our national manners. That a change for the better has occurred in recent years, and is still in progress, is matter of common observation and attested by many indications. The new report shows in the most satisfactory way that this improvement is general in its character, being exhibited by all classes of the people and all parts of the area under observation. An absence of summary and comparative tables makes it a little difficult to perceive at a

Digitized by Google

glance what is the exact meaning of the figures given, but it is evident upon the face of them that they mark an improvement upon previous years, for in almost every case the number of arrests grows steadily less from year to year; and this in spite of increase of population. Thus, for the whole of England and Wales the figures are—for 1884, 15,942 convictions; for 1885, 14,658 convictions; for 1886, 12,917 convictions. Here it will be seen that the number of convictions has been actually reduced in two years by 3000 odd, or nearly 19 per cent. If allowance were made for the increase of population within the same period, the ratio of improvement would be seen to exceed this figure. As might be supposed, the return shows a much higher proportion of drunkenness in the case of urban than in that of rural populations. In agricultural districts the convictions vary from one in ten thousand to one in a hundred thousand inhabitants, whereas in the metropolis they run as high as one in fourteen hundred, and at Manchester, which enjoys an unenviable pre-eminence in this respect, they reach the appalling figure of one in three hundred and fifty. Altogether, Lancashire, with its teeming population and its laborious industries, makes but a poor figure in this report. The one satisfactory feature in its record is that it has fully shared in the improvement of recent years. It must, of course, be borne in mind that police supervision is much more efficient in these districts, where vast populations are crowded thickly together, than in sparsely occupied rural parts; but when all allowance is made for considerations of this sort, it is quite clear, even on a mere comparison of different towns, that there are localities, and especially in the mining districts, which in point of sobriety lag far in the rear of our civilisation.

CONDURANGO IN CANCER OF THE STOMACH.

FIFTEEN years ago there was introduced from Brazil a remedy which was claimed to be a specific for cancer. Since then, as before, other remedies have been similarly vaunted, and none have stood the test of experience. The remedy in question was condurango bark, of which a trial was made at the Middlesex Hospital, the negative results being read before the Clinical Society by Messrs. Hulke and De Morgan (Clin. Soc. Trans., vol. 5). In Germany almost the only favourable report came from Professor Friedreich, who related instances of its value in gastric cancer. Since then it has fallen much into disrepute, having been regarded as little better than a stomachic, and prescribed thus with advantage (Wilhelm: Year-book of Treatment, 1886, p. 49) in cases of carcinoma and ulcer. But Dr. Riess of Berlin has just published (*Berl. Klin. Wochensch.*, March 7th) some striking testimony to the value of the drug in gastric carcinoma, more conclusive than any that has hitherto appeared. It is noteworthy that he doubts whether its qualities as a stomachic are better than those of other drugs of that class, and that he has not found it efficacious in cases of cancer where the stomach is not primarily involved. (Messrs. Hulke and De Morgan's reports did not deal with gastric cancer.) It was in cases presenting the symptoms of cancer of the stomach (many with a tumour) that the best effects were noticed. In 105 such cases—i.e., where gastric cancer was diagnosed—treated at the General Hospital from 1878 to 1886, condurango was prescribed, and in no case, even in those in the last stage, without some effect. The drug was often given every hour—the total amount per diem reaching ten grammes of the decoction—and continued for long periods without ill effect. The appetite improved in a few days, vomiting and pain diminished, and eventually ceased, and the patient gained in weight. Whether life is actually prolonged is, of course, difficult to prove; but Riess quotes statistics which show that the cases treated with condurango, both the fatal ones and those discharged in improved health, remained much longer in hospital than those not treated by the drug. He even states that of sixty-four cases in which a palpable tumour was present, in seventeen it diminished in size, and in eight quite disappeared; and he details three cases of such disappearance of obvious tumour, which, subsequently dying, presented only cicatricial structure, with no trace of malignant disease. Obviously, before we can accept such cases as examples of the *cure* of cancer we must be certain that the original diagnosis was correct, and the same scepticism may be allowed respecting the whole series of cases. For cancer of the stomach may not only be latent, but may be simulated by non-malignant ulceration, as every physician knows. Dr. Riess fairly discusses this point, being quite alive to the objection. He claims, at least, that condurango has some local effect upon a diseased stomach, and considers that in all suspected cases it should be prescribed. It need hardly be pointed out that a local action as here claimed is a very different thing from a specific action in cancer generally, which was sufficiently disproved by the observations at the Middlesex Hospital.

THE "RELATIVE RANK" QUESTION.

WE see no reason to modify the opinion we have already expressed, and which is fully borne out by the statement of the Secretary of State for War in the House "that the abolition of the term 'relative rank' had not altered the position of the medical officers in any respect whatever." It must not be lost sight of that the abolition of the *term*—for the *fact* of the existence of relative rank must exist so long as medical officers are placed in relation to other officers—is not confined to medical officers alone, but applies also to the officers of the Adjutant- and Quartermaster-General's staff and to all the departments of the army. It is difficult, therefore, to understand how the change can be deemed derogatory to medical officers. But this would seem to be the view advanced by those who have called in question the good faith of the authorities in this matter. The fact is, that so much distrust has been engendered in the Army Medical Service by past experience, that we cannot be surprised at its sensitiveness to, and suspicion of, any changes likely to affect it in any way; and undoubtedly the result of the statements put forth, unfounded though they be, has been to create a strong feeling of that nature on the part of the medical officers. It would be perfectly easy, as it appears to us, for the Secretary of State to issue a satisfactory official statement on the subject by so far altering the wording of the Warrant as to prevent its being misinterpreted. This could be effected by a clause enacting that "the respective grades in the Army Medical Staff shall take rank with, and carry all precedence and advantages attaching to, corresponding military rank," and following this up with the classification laid down in paragraph 125*a* of the Warrant. We cannot see any difficulty in such a course, and it would remove all ambiguity as to the position of the medical officers.

RUPTURE OF THE INTESTINE.

ON March 6th Mr. John Croft of St. Thomas's Hospital performed abdominal section on a patient aged thirty-four, who had been admitted with acute peritonitis due to injury received about eighteen hours previously. The patient, who had received severe injury to the abdomen the night before, walked to the hospital. He had vomited, and in addition to the symptoms of most acute peritonitis and a temperature of 103°, had some dulness in the hypogastric region. A rent was found almost dividing the small intestine; there was feculent material in the peritoneal cavity, and acute inflammation in the neighbourhood. The peritoneum was washed out with a 20 per cent. solution of boracic acid, and the intestine sutured to the wound. Since the opera-

Digitized by Google

tion his progress has been very satisfactory; he has had neither pain nor vomiting, and the distension of the abdomen has disappeared. Although he was complaining of cough and had a rapid pulse, his condition was otherwise favourable on the 10th. The same surgeon operated on the 4th in a case of abdominal injury, accompanied by much hæmorrhage into the peritoneal cavity, and removed the spleen, the hæmorrhage being due to an extensive laceration of that organ. The patient, however, did not survive the loss of blood and the additional shock of the operation.

THE MINUTE ANATOMY OF THE BRACHIAL PLEXUS.

A PAPER of some interest appears in the forty-first volume of the Proceedings of the Royal Society, under the authorship of Dr. W. P. Herringham. The results were obtained from careful dissections, partly of fœtuses or still-born children and partly of adult subjects. The following conclusions were arrived at:—1. Any given (nerve) fibre may alter its position relatively to the vertebral column, but will maintain its position relatively to other fibres. 2. Of two muscles, or of two parts of a muscle, that which is nearer the head-end of the body tends to be supplied by the higher, that which is nearer the tail-end by the lower, nerve. 3. Of two muscles, that which is nearer the long axis of the body tends to be supplied by the higher, that which is nearer the periphery by the lower, nerve. 4. Of two muscles, that which is nearer the surface tends to be supplied by the higher, that which is further from the surface by the lower, nerve. The next conclusions relate to sensory nerves. 5. Of two spots on the skin, that which is nearer the pre-axial border tends to be supplied by the higher nerve. 6. Of two spots in the pre-axial area, the lower tends to be supplied by the lower nerve, and of two spots in the post-axial area, the lower tends to be supplied by the higher nerve.

THE PORT OF LIVERPOOL.

OUT of 20,928 vessels entering the port of Liverpool during 1886, 4120 were inspected by the sanitary officers, and 276 were found to be defective. The coasting trade is now largely carried on by steamers, and the accommodation for the crews is stated to be both good and double that which is usually provided. The steamers carrying Lascars were also found to be in fair condition, and in no case was any infectious disease found on board. The number of emigrants was large, reaching 191,491; and the American Government have acted wisely in appointing medical inspectors to examine those going to that country, in order to ascertain if any of them have come from infected districts. If they have, measures of disinfection and other precautions are adopted; and some intending emigrants have, in the first instance, been isolated in hospital. During 1886, the number of cases of infectious sickness found on board was forty-six, and in a majority of instances removal to hospital was adopted by Dr. Stopford Taylor.

CANCEROUS AXILLARY GLANDS.

AT the Harveian Society, on the 3rd inst., the entire evening was taken up in the discussion of an extremely practical paper by Mr. Mitchell Banks, upon the advisability of extirpating the axillary glands in all cases of amputation of scirrhous mammæ. Mr. T. Bryant went a considerable way with the author in his bold and thorough treatment, but felt that there must still be a considerable number of patients for whom the old-fashioned or incomplete operation would be preferable. Mr. Pick took exception to much of the argument put forward in the paper, as also did Messrs. Butlin and Cripps. The latter two gentlemen brought forward statistics from St. Bartholomew's Hospital and elsewhere which differed widely in percentage results; Mr. Cripps' figures, indeed, offered considerable support to Mr. Banks' views. Mr. T. Smith suggestively remarked that surgeons must not lose sight of the fact that many women are living in comparative comfort who for years have been the subjects of cancer of the breast which has never been subjected to any surgical treatment. This Mr. Banks readily accepted, and remarked that far better was it to leave the patient alone than to inflict on her any incomplete operation. The President (Mr. Edmund Owen) expressed himself strongly in favour of opening up and clearing out the axilla in every operation for mammary cancer, whether enlarged glands have been previously felt there or not.

THE NEW PHARMACY BILL.

A BILL has been introduced in the House of Lords by the Earl of Milltown, under the title of the 'Pharmacy Acts Amendment Bill," to amend the Pharmacy Acts of 1852 and 1868. It is proposed to provide for the division of the examination into preliminary and other parts, and to make it incumbent on candidates presenting themselves for the final test to produce certificates of having attended a course of lectures on materia medica, botany, and chemistry. They must also have served for a period of not less than three years as pupils or apprentices in the shop of some duly-qualified chemist or druggist. The Pharmaceutical Society of Great Britain is to be entrusted with the power of regulating these examinations, and the Council of that body may, under certain circumstances, waive the whole or any part of the term of apprenticeship, provided they are satisfied that the candidate has by other means received adequate instruction. It is not intended that the Act shall apply to Ireland.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—Professor Arlt, the eminent oculist, at Vienna, on the 7th inst., at the age of seventy-five, after a long illness. Dr. Reinhold von Reichenbach, whose name is well known in the chemical world, on Feb. 23rd, at Gratz. Professor August Wilhelm Eichler, director of the Royal Botanic Garden and Museum at Berlin, at the age of forty-nine. Dr. A. Borodin, professor of Organic Chemistry in the Military Medical Academy of St. Petersburg.

THE EXISTENCE OF PEPSINE AND TRYPSINE IN URINE.

DR. VASILEVSKI, at Professor Chudnovski's suggestion, recently undertook some observations on the urine of twenty patients suffering from various diseases, in order to confirm the statements made by a number of authors—Brücke, Grützner, Sahli, Leo, Mya, Belfanti, and others—as to the constant existence of pepsine and trypsine as urinary constituents. He found that in both healthy and diseased states pepsine in greater or less quantity was constantly present. The smallest quantity was found in patients who were badly nourished, the state of nutrition of the body having apparently more influence upon the amount of pepsine in the urine than the nature of the disease. The least quantity of pepsine was found in the urine of a patient with pulmonary phthisis four days before death, and in that of another who suffered from carcinoma of the pylorus. In this case the pepsine was greater in amount when the pylorus was pervious and less when it was impassable and the patient vomited matter in a high state of fermentation. A high body temperature appeared to lessen the pepsine. In three

Digitized by Google

cases in which the urine contained albumen, the quantity of pepsine coexisting with it appeared to be much the same as might have been expected from the state of the patient's nutrition if there had been no albuminuria. In regard to trypsine Dr. Vasilevski was unable to obtain definite results.

THE MARGARET STREET INFIRMARY.

AT a meeting of the Medical Board of the North London Consumption Hospital, held on Monday last, the following resolution was carried:—

"That the medical staff of the North London Hospital for Consumption and Diseases of the Chest are unanimous in their sympathy with the action of the members of the Margaret-street Infirmary—Drs. Hawksley, Cholmeley, Carr Beard, Phibbs, Willis, Walford, and Powell—who lately resigned their appointments under painful circumstances; and, further, that the secretary be instructed to forward a copy of this resolution to Dr. Hawksley, late senior consulting physician to the infirmary, and ask him to convey the substance of this resolution to his former colleagues."

We are glad to see the above timely expression of sympathy on the part of the medical staff of the North London Hospital for Consumption. It will no doubt be gratifying to Dr. Hawksley and his late colleagues. Meanwhile, it would be interesting to know what effect the resignation of these gentlemen will have on the position and future management of the Margaret-street Infirmary.

GASTRITIS IN RENAL DISEASE.

IN a paper read before the Société de Biologie (*Le Progrès Méd.*, No. 9), M. Pilliet described the lesions of the gastric mucous membrane in the dyspepsia of renal and urinary disease. The lesions—observed in a large number of cases of different kinds of renal disease—comprise infiltration of the connective tissue in the round and fusiform cells in groups between the glands or in bands along the vessels The gland tubules are diminished in number, much shortened, often dilated at their lower extremity, flattened superficially, and variously contorted. The cubical or prismatic cells are ill developed, as in the new-born, and show little or no formation of Nussbaum's peptic granules. The changes are best marked in interstitial nephritis, and resemble those described by Parrot in athrepsia, those met with in chronic alcoholic gastritis and in cirrhosis of the liver, and in gastritis of tubercular subjects.

BURIAL REFORM.

THE reply given by Mr. Plunket in the House of Commons to the question recently put to him by Mr. Baggallay respecting Brompton Cemetery suggests very serious reflections as to our present mode of burial. From that reply (a note of which appeared in THE LANCET of the 5th inst.) it appears that the cemetery contains in all 38 acres and 20 perches, and that there now remain 4 acres and 34 perches available for burial purposes. The space already used is therefore less than 34 acres, and in this there have been buried the enormous number of 135,617 bodies, an average of 3988 per acre. It has been calculated that 1000 graves can be made in every acre of land set apart for burial purposes, leaving a reasonable margin for spaces between graves, walks, &c. Hence, as the depth of graves is often eleven or twelve feet, and sometimes even deeper, the figures, large though they at first appear, are not excessive. Nor would there be anything to fear if it were the truth that all these bodies are really buried. But, as Mr. Seymour Haden has said, speaking of modern burial, a large proportion cannot be considered as buried at all. The first burial in Brompton cemetery took place in 1840, and, as it has always been what may be termed a fashionable place of interment, the probabilities are that a large proportion of the burials have been in lead coffins and in vaults or bricked graves. The result is, as it always must be when the dead are disposed in this manner, that the cemetery becomes filled with what Mr. Haden severely, but truly, describes as a mass of boxed-up putridity. It appears, moreover, that the burials therein still average in round numbers 5000 yearly, and that the Government derived last year a profit of £7070 from the cemetery. Considering all these circumstances, and also how completely the cemetery has become surrounded by dwellings it appears only reasonable that, if burials are to continue there every inducement should be made by reduced tariff &c. to bury in perishable coffins and in graves. It would indeed be well if all existing vaults or bricked graves could be converted into real graves by filling them up with earth or charcoal, so as to neutralise the poisonous gases which must sooner or later pass through the best soldering or most perfect cement. Meanwhile, much may be done by the force of example, and if the friends of the next titled and other celebrities who may be buried there would set the example of burial in perishable coffins, and in the earth, the example would soon be followed.

RUPTURE OF THE BLADDER.

A PATIENT was admitted into St. Bartholomew's Hospital on the morning of March 1st with symptoms of a ruptured bladder, in consequence of a blow on the hypogastrium whilst the bladder was distended. The injury had been received the previous evening, and Mr. Walsham operated soon after admission. A large quantity of urine escaped from the peritoneal cavity when the abdomen was opened, and a rent about an inch and a half long was found in the bladder wall. Sutures were used, passing through the peritoneal and muscular coats only; the abdominal cavity was irrigated with a 1 per cent. solution of boracic acid, and the abdominal wound closed as after ovariotomy. The patient suffered very little shock, and passed his urine naturally without the aid of a catheter every four hours. There has been no sign of peritonitis, and he may be looked upon as convalescent.

DENTAL IRREGULARITY.

MR. CHARLES TOMES, in his presidential address delivered at the Odontological Society, spoke of the influence of heredity in the production of dental irregularities. He does not believe, as has been maintained, that these deformities are things of quite modern date and due to disturbed innervation, the result of over-pressure (like the headache of Board School children), and points to the portraits by Vandyke at the Grosvenor Gallery and the exhibition of the old masters at the Royal Academy as showing several examples of dental irregularity, such as underhung jaw and protrusion of the upper incisors.

TREATMENT OF CHOLERA IN BUDA-PESTH.

IN a paper lately read before the Royal Buda-Pesth Medical Society, Dr. B. Anayán gave some particulars of the results of various kinds of treatment during the recent cholera epidemic in Buda-Pesth, an epidemic which he considered to have been of a mild character. He divided his cases into four groups—viz., 76 of choleraic diarrhœa, 85 of cholerine, 90 of slight cholera, and 454 of severe cholera. In the first three groups and in 180 of the cases belonging to the fourth group he employed only enemata; in the rest he employed, besides enemata, hypodermic injections of tannin and opium, corrosive sublimate, or hydrochloric acid. The results were that the cholerine and choleraic

Digitized by Google

diarrhœa cases were all cured, and 63·6 per cent. of the slight cholera cases, but only 20·7 per cent. of the severe cases, which were treated with enemata only, so that in all the milder forms enemata had proved most successful. In the severe cases where hypodermic injections were used 38·6 per cent. recovered.

TRAVELLING MEDICAL REFEREES.

ACCORDING to information from colonial sources, the lot of medical officers attached to some Australian insurance companies is far from being a happy one. The "travelling medical referee" is one of those persons upon whose judgment and integrity the success of such associations chiefly depends. His position, privileges, and emoluments unfortunately stand in a nearly inverse ratio to the value of his services. These consist in making a series of professional visitations in town or country in company with an agent, who canvasses the inhabitants in favour of the office which he represents. The agent is commonly a hail-fellow-well-met, and the medical examiner frequently finds it almost obligatory to conform to the rough free-living customs of a young and growing colony. Of work and fatigue he has more than enough, food is apt to be inferior, and accommodation is but another name for barbaric dirt and roughness. The pay allowed is in some cases not illiberal, provided that business is brisk; in others it does not vary with the market, but is fixed at the low rate of four guineas per week. As to provision in case of accident or illness, the principles of the society do not, as a rule, stretch as far as the requirements of its medical referees. Altogether the life of these gentlemen appears to present few, if any, enviable features.

HYPODERMIC INJECTIONS IN ACUTE ANÆMIA.

DR. PREGALDINO of Ghent, taking into consideration the observations of Kronecker, showing that in acute anæmia death is not directly due to the want of oxygen owing to the paucity of the blood-corpuscles, but to the diminution of pressure in the bloodvessels, suggests that in these cases pressure may be restored either by intravenous injections, or, more simply and less dangerously, by hypodermic injections into the cellular tissue. He made observations on eighteen dogs, injecting into the cellular tissue a solution of common salt of the strength of 6 per 1000, and warmed to 37° C. This he found was very quickly absorbed, raising the blood-pressure in a quarter of an hour. Dr. Pregaldino has been requested by the Royal Belgian Academy of Medicine to continue his experiments.

MEDICAL HONOURS IN ITALY.

KING HUMBERT (*motu proprio*) has nominated Surgeon-Major Francesco Guerriero Chevalier of the Order of Saints Maurice and Lazarus, in consideration of professional duty heroically discharged in the Abyssinian campaign. Similar honour, equally merited, will, it is understood, be shortly conferred on others of the profession who have, at great risk to life and limb, saved many sufferers from the recent earthquakes in the Ligurian littoral.

ELECTROLYSIS OF AN ANEURYSM IN SPAIN.

DR. BERNARDO DIEZ UBELAR of Molinaseca publishes in *El Siglo Médico* the notes of a case of aneurysm of the first part of the aortic arch in a military officer, which produced dysphagia and terrible suffering, and required immense doses of morphia, so that the patient entreated that some operation might be performed, expressing himself as ready to run any risk in the hope of obtaining some relief. Electrolysis by means of needles was therefore resorted to, a Spamer battery being used. At first the maximum number of cells employed was ten, but in the later sittings twenty were brought into action. Some slight effect was produced, the tumour becoming small and more solid; the distressing dysphagia also diminished, but the pain remained as severe as before.

MEDICAL ATTENDANCE ORGANISATION COMMITTEE.

THIS Committee met on Tuesday, Sir Spencer Wells presiding. The principal resolutions were to the following effect:—That persons joining were to be approved by the medical officer under whom they wish to be registered. The question of an entrance fee was postponed, except for emergency cases, and, after much discussion of several amendments, the following resolution was passed: "Persons requiring immediate attendance must pay an entrance fee of 2*s.* 6*d*, which shall entitle them to treatment for one week, after which, should they continue ill, they shall pay 1*s.* per week if able to call on the doctor, and 2*s.* 6*d.* if visited at home. Upon recovery they shall be expected to continue as ordinary members with the consent of the medical officer." A further resolution was passed to guard the medical officers and the institution against an influx of chronic cases on ordinary terms, but providing for their admission at special rates, subject to the approval of the medical officer. It is necessary to remember that all these resolutions apply to persons whose wages do not exceed 30*s.* (for single persons), or 45*s.* (for a family). At the next meeting the questions of midwifery fees, general rules, fines, &c., are to be disposed of, after which it is hoped that the great point of a union between hospitals and provident dispensaries may be reached. Several hospital physicians are expected to take part in the discussion.

THE NEW EXAMINATION HALL.

ON and after Monday next, the 14th inst., the business of the examinations for diplomas of the Royal Colleges of Physicians and Surgeons of London under the old regulations, as well as under those of the Examining Board, will be conducted in the new Examination Hall, situate, as our readers are aware, on the Victoria Embankment.

ALLEGED INACCURATE CERTIFICATION OF DEATH.

AT a recent meeting of the Dartford Petty Sessions, Mr. Thomas Wheeler, medical officer of health for Bexley, was charged on a summons with making and issuing a false certificate of the death of a woman named Asker. For the prosecution it was stated that Mr. Wheeler certified that he had seen the deceased on Dec. 24th, when as a matter of fact he had seen her on the 19th. For the defence it was contended that the object of the Births and Deaths Registration Act was simply to ascertain the cause of death, and if this were correctly given no medical practitioner could be compelled to give other particulars. The magistrates accepted this view, and on the facts dismissed the summons, making, however, no order as to costs.

FINE FOR FALSE USE OF MEDICAL TITLES.

ON the 3rd inst. David Thomas of Peckham-rye—who must not be confounded with Mr. R. W. Thomas, L.R.C.P. Ed., of Temple Villa, Rye-lane—appeared to an adjourned summons, taken at the instance of R. H. S. Carpenter, for having on January 31st unlawfully taken a title, that of "Dr.," implying that he was registered as a medical practitioner, under the Medical Act of 1858. Mr. Pridham showed that the defendant said, in answer to a question, that he was "Dr. Thomas." This was denied, but the

Digitized by Google

magistrate, Mr. Chance, decided that the Act had been violated, the object of which was to enable the public to distinguish between qualified and unqualified medical men. The defendant was ordered to pay £3 fine and £4 costs, but an appeal was granted.

THE BRITISH MEDICAL ASSOCIATION.

AT the fifty-fifth annual meeting of this Association, to be held at Dublin in the first week of August next, Dr. John T. Banks, Regius Professor of Physic in the University of Dublin, will succeed Dr. Withers Moore as President. The Address in Medicine will be delivered by Dr. W. T. Gairdner; the Address in Surgery by Dr. E. Hamilton; and the Address in Public Medicine by Dr. S. Haughton. Dr. G. F. Duffey will act as local hon. secretary.

A NEW SKIN HOSPITAL.

WE have received intimation by a paragraph, which seems meant for the press generally, that it is intended to set up a new Skin Hospital in Cranbourne-street, Leicester-square, to be "promoted by Mr. James Startin and Mr. Walter Pocock, for the gratuitous treatment of poor persons suffering from skin disease." We trust this proposal will be reconsidered. Leicester-square is already blessed with a Skin Hospital, and it is a poor compliment to it to erect another. Besides, the whole charity of the community just now is taxed to the utmost to sustain those great general hospitals where skin disease can be treated with reference to its constitutional bases. Mr. Startin will agree with us, too, in thinking that hospitals should be "promoted" by the public, and not by members of the profession. For all these reasons, and others, we trust that Mr. Startin and his friend will abandon a project which is not likely to succeed, and which would only injure other institutions, where their knowledge of skin disease might be exercised with greater advantage to the community and to the poor.

TYPHOID FEVER AT MEXBOROUGH.

AT a recent meeting of the Mexborough Local Board of Health, Mr. Sykes, the medical officer of health, reported that since the commencement of the outbreak, which had principally centred itself at Sparrow Barracks and Clay-lane, there had been a total of eighty-five cases. Of these, four had died and eighteen remained ill. Since then three fresh attacks had been heard of. The Local Government Board are pressing on the authority the action recommended to them by Mr. Spear of their medical department, and locally some preliminary action has been decided on as to the establishment of an Isolation Hospital, which, it may be hoped, will in the future aid in staying the progress of such epidemic diseases as that from which the town is suffering.

A CASE FOR INQUIRY.

THE name "Dr. T. Young, L.R.C.P., L.R.C.S., L.M.," is paraded in the large paragraph advertisements of Mr. E. W. Alabone, to whom allusion was made in our last issue. We ask why the Colleges from whom "Dr. T. Young" obtained his diplomas have not inquired into the matter.

CHOLERA IN SICILY.

CHOLERA is stated to be still prevalent at Catania in Sicily, although the number of cases and deaths is not numerous. According to information from Rome, six more attacks, of which four were fatal, were announced on the 5th inst.

FOREIGN UNIVERSITY INTELLIGENCE.

Basle.—A new ordinary professorship is about to be created, which, strange to say, has not up to the present time existed—namely, that of Midwifery and Gynæcology. The number of medical students has increased since 1862 from 30 to 130. Up to 1873 there were only four professors, now there will be seven.

Berlin.—Professor Gusserow has been selected to fill the chair of Obstetrics vacant by Professor Schroeder's death, the name of Professor Winckel of Munich being mentioned for Professor Gusserow's post.

Bonn.—Professor Ludwig of Giessen has been appointed Professor of Zoology and Comparative Anatomy.

Leipsig.—Dr. Benno Gottlob has been granted the position of Honorary Professor. Professor Hankel, Chief of the Physical Institute, has retired, being in his seventy-third year.

Montpelier.—The chair of Pathological and Histological Anatomy is vacant.

Nancy.—A serious fire has occurred in the buildings belonging to the Faculty of Medicine, the laboratory and collections belonging to the therapeutical department, as well as the natural history collections, having been destroyed.

Paris.—The Faculty of Medicine has thus arranged the candidates for the office of Dean: (1) M. Brouardel; (2) M. Jaccoud.

Zurich.—Professor Wyss is to have charge of the new Hygienic Institute.

A LARGELY attended meeting of the Portsmouth Hospital committee was held on the 4th inst., to consider the proposal made by the Admiralty in reference to reopening the lock wards. The Admiralty offered to contribute £35 a year for each bed occupied, provided the number did not exceed thirty, while the minimum contribution should be for fifteen beds, whether occupied or not. The committee agreed to accept the offer if the minimum number was increased to twenty-five and the maximum to thirty-two, without any reference to compulsory powers. It was stated that there are at the present time close upon 300 of this class of cases at Haslar Naval Hospital, and that the disease is so prevalent that only the worst cases could be received at the Station Hospital, Portsea; also that while there were only twelve of these patients at the workhouse in 1882, there are now fifty-five.

A BILL has been prepared for presentation to Parliament by the friends of some of the London and other hospitals which proposes "to restore the exemption from taxation which charitable institutions enjoyed for 250 years," but to which it is alleged they have been subjected since 1866 owing to the decision of the House of Lords in the case of the Mersey Docks and Harbour Board.

ON April 27th the Senate of the University of London will elect examiners in the departments of Arts and Science, Laws, Medicine, and Music. In the medical department two examinerships in Medicine and one in Forensic Medicine are vacant, the retiring examiners being eligible for re-election, and intending so to offer themselves.

IT is stated that Sir W. Foster, M.D., will be asked, after the funeral of the late member for the Ilkeston division of Derbyshire, to become the Liberal candidate for that constituency.

ON the 4th inst., at the Royal Institution, Mr. Victor Horsley, F.R.S., delivered an address on "Brain Surgery in the Stone Age."

Digitized by Google

HERBERT PERCY FREUND, who has been repeatedly charged with creating disturbances at St. Paul's Cathedral, was again charged with the same offence on the 7th inst. Medical evidence was given on the question of the sanity of the defendant, and, no evidence being offered by the authorities of the Cathedral, he was discharged.

As will be seen by an announcement in our advertising columns, a change has been made by the Senate of the University of London in the time of holding the next Matriculation Examination—viz., from the week commencing Monday, June 20th, to the preceding week, commencing June 13th.

AN important inquiry has been opened by Mr. S. J. Smith, civil engineer, of the Local Government Board, as to the sewerage of West Cowes. The proposed scheme is a costly one, and meets with considerable opposition. The inquiry stands adjourned to March 19th.

DR. HUNTER STEWART and Mr. COSMO BURTON are engaged in making an analysis of the air of Edinburgh. A report on the whole work will be submitted to the Public Health Committee as soon as the investigations are completed.

A BILL to amend the law relating to the election of coroners will be introduced in the House of Commons to-night (Friday) by Mr. Wootton Isaacson.

DR. SAMUEL FENWICK has been elected a member of the Royal Institution of Great Britain.

Pharmacology and Therapeutics.

CHAPOTEAUT'S MORRHUOL.

THE difficulty frequently experienced by patients in taking cod-liver-oil has induced M. P. Chapoteaut, the well-known pharmacist of Paris, to turn his attention to the subject, and he has recently introduced a preparation of this valuable remedy, which proves to be of considerable utility in the treatment of phthisis and other wasting diseases. The active principle, if such it may be called, is extracted and enclosed in capsules, which, in the words of the prospectus, have "the advantage of possessing in a small volume the curative medicinal properties without the inconvenience of the oil." It is claimed for morrhuol that it represents twenty-five times its weight of the crude drug. Professor Germain Sée and his colleague, Dr. Labadie-Lagrave, in the fifth edition of their clinical lectures recently published, speak highly of extract of cod-liver oil, and assert that it is not only tolerated without difficulty, but is readily absorbed. We find that some patients take the capsules who certainly would not take the oil. Whether morrhuol is equally efficacious as a therapeutic agent remains to be seen, and can only be determined by a series of clinical observations extending over many months. We think, however, that we are justified in calling attention to what may prove to be a new departure in the treatment of certain intractable diseases. The capsules may be obtained direct from M. Chapoteaut, 8, Rue Vivienne, Paris.

MELON ROOT AND OIL OF BEN (MORINGA APTERA).

The above possess purgative and emetic properties. An emetic principle has been extracted from the root by Torosicviez. A solution containing nine centigrammes of it is, says the *Pharmaceutical Journal*, sufficient to induce emesis. Fifty centigrammes of powdered root is necessary to cause vomiting.

HASCHISCH PURUM AND CANNABINON.

This is a preparation of cannabis indica prepared by treating the alcoholic extract of Indian hemp with caustic alkali, by which all acid ingredients are solved. The brown soft resinoid residue is "pure haschisch," and is composed of the soft resin cannabinon and the alkaloid tetanine. It is insoluble in water, but forms golden-yellow solutions in alcohol, ether, and chloroform. A third of a grain is said to act as a cerebral stimulant, and a larger dose causes all the symptoms, including sleep, of Indian hemp. The drug should be in a fine state of division, and may be given in pastille form, with powdered cacao or roasted coffee as a vehicle. Tannic acid dissolves out the alkaloid on which the stimulant action depends, whilst the remaining cannabinon has the narcotic property. Cannabinon is triturated with sugar of milk in the strength of 10 per cent. Made up with cocoa or coffee in pastile form, it may be given as a hypnotic, in doses of one-half to one grain and a half, especially for hysterical or insane patients, but it is contra-indicated when heart-disease exists.—(*Pharmaceutical Journal.*)

THE USE OF IODOL IN BELGIUM.

Dr. Edouard de Smeth, in a clinical lecture on iodol given at the Hospital of St. Pierre, Brussels, details several cases of syphilis and soft chancres in which iodol proved very useful. In one of these, iodoform had first been used, but had to be abandoned because of the objection made to its smell by the landlord of the hotel in which the patient was staying. The lecturer also mentioned a case of very obstinate varicose ulcers which had been treated with great success by one of his colleagues by an ointment composed of five grammes of iodol in thirty grammes of lard. He says that iodol is prescribed in Belgium by Dr. Coppez in various ophthalmic cases, by Dr. Houzé in tubercular ulceration of the throat, and by Dr. Lebrun in the form of ethereal injections in endometritis, also by others in various affections under the forms of iodol-collodion, iodol-bougies, &c. In addition to the experiences of Belgian surgeons, those of foreign observers were mentioned, especially those of Marcus of Pyrmont, showing by injections of iodol and iodoform in animals that iodol is far less poisonous than iodoform.

VASELINE FOR HYPODERMIC MEDICATION.

This method of hypodermic medication is extending, especially in France, where it is advocated by M. Meunier, of Lyons, as a vehicle for the introduction of active principles into the system. It is contended that vaseline is absolutely harmless to the tissues, and may be employed in large doses without causing accidents. But the vaseline must be perfectly pure. Pure vaseline treated with warm sulphuric acid does not blacken, but any impure specimen would. Eucalyptol has been thus employed in phthisis, and turpentine in sciatica. Iodoform, phenol, iodine, and camphor may be injected in the strength of 1 per cent., and thymol in ½ per cent., or menthol 10 per cent.

RHUS AROMATICA FOR NOCTURNAL ENURESIS.

A fluid extract has been sent into the market by Parke, Davis, and Co. It is prepared from the cortex of the root of the rhus aromatica, sweet sumac. It acts on the plain muscular tissue of the bladder, uterus, and rectum, and may be employed to check hæmorrhages in these situations. Atonic dyspepsia is said to have been relieved by it. Dr. Unna, after a trial of three years, believes the extract to be very efficacious in the nocturnal enuresis of children. Five drops may be given morning and evening to a boy two years old, and ten-drop doses to children of six.

SALICYLATE OF SODA IN GONORRHŒA.

Dr. Avsitidiski recommends salicylate of soda in gonorrhœa; the quantity he gives is thirty grains a day dissolved in linseed-tea. The way in which this acts is by being eliminated by the urine, and thus washing out the urethra with an antiseptic solution. Dr. Avsitidiski tried the effect of a 2 per cent. salicylate of soda solution as an injection, and found that it acted similarly to a solution of boracic acid of the same strength, rapidly changing the puriform secretion to one of a mucous character.

MENTHOLEATE.

Mentholeate is a solution of menthol in oleic acid, and is recommended by Professor Remington as the best form for the outward application of menthol. Two hundred grains of menthol may be dissolved in half an ounce of oleic acid by heating together in a test-tube.

Digitized by Google

IODOFORM IN HEART DISEASE.

M. Testa has employed iodoform in cases of organic lesion of the valves. The administration of small doses of iodoform (seven centigrammes—about a grain—in four pilules, one to be taken every two hours) rapidly dissipated the functional derangements dependent on the valvular disease. The experimental results obtained in dogs completely concur with those furnished by clinical experimentation in demonstrating that in dogs iodoform retards the cardiac contractions, and this delay increases the total duration of each cardiac cycle, and also the efficiency of the systole.

PHENOL MERCURY.

The chemical formula of this mercurial compound is $C_6H_5OHg.OH$. It is given in the form of pills, each containing two centigrammes of the preparation. Two pills may be given the first few days, and the number gradually increased to six. Salivation and stomatitis are said to be but very occasionally produced.

LOBELINE AND INFLATINE.

These are two alkaloids obtained from the seed of lobelia inflata. The former has powerful emetic properties, and the emesis is not followed by disagreeable symptoms. The powdered alkaloid is very irritant to the nasal passages, perhaps more so than veratrine. The inflatine has not any therapeutic effects, so it is stated.

NASAL POLYPI.

It is recommended by Dr. Bell of Canada to treat nasal polypi by daily injection of tannin, from five to ten drops of a concentrated solution being injected by means of a hypodermic syringe. After a few days of this treatment the polypus sloughs and comes away without bleeding.

THE HIGH ALTITUDE TREATMENT OF PHTHISIS.

(FROM A SPECIAL CORRESPONDENT.)

No. III.

Davos-Dörfli; Frauenkirch; Wiesen; St. Moritz; The Maloja,—Concluding Remarks.

HAVING dealt fully with the general principles of the high altitude treatment of phthisis with special reference to Davos, I shall conclude by a brief consideration of the other Alpine sanatoria. Frauenkirch and Davos-Dörfli need not detain us, being both in the Davos valley and sharing in the general climatic conditions of Davos-Platz. Owing to the rapid increase of patients at the latter village, they are likely to grow in popularity as the opinion gains ground that the aggregation of large numbers of consumptives is a peril to be shunned. Davos-Dörfli has more sunshine, but less shelter than Davos-Platz. The climatology of Frauenkirch is practically identical with that of the parent sanatorium.

Wiesen demands a more extended notice, as it possesses many attractions as a health-resort, and probably has a future before it. Situated on the side of a declivity which slopes abruptly down to the wild gorge of the Landwasser, surrounded by pine woods, and encircled by a range of magnificent snowy peaks, Wiesen possesses all that Alpine charm of scenery which Davos so conspicuously lacks, and is hardly inferior to the latter in all the essential requisites of an admirable sanatorium. It possesses rather more sunshine, an almost equal immunity from wind, and a site superior to that of Davos for the purposes of drainage. From its situation on the brow of a hill overlooking a deep Alpine valley, it might be conjectured that Wiesen would be much exposed to winds, but the gorge of the Landwasser is so deep and its bed so far below the level of the village that the valley wind sweeps past without rising so high as the site of the hotels for invalids. The chief point of difference between Davos and Wiesen arises from the fact that the latter lies at a considerably lower elevation, and hence has a shorter winter and a higher mean temperature, amounting to about 2° C (Tucker Wise). The climate is thus milder and less bracing than that of Davos, and hence likely to prove advantageous in those cases where the latter proves too stimulating. There can be little doubt that Wiesen is capable of affording as good results as Davos, and it seems particularly worthy of trial in those doubtful cases where dyspepsia, insomnia, or deficiency in circulatory vigour renders recourse to the mountains a tentative measure. There are two good hotels where ample provision is made for the comfort of the invalid; but the village itself is one of the smallest and poorest in Switzerland, and the visitor must be prepared to dispense with many of the social attractions afforded by Davos. Wiesen can be recommended only to those who are superior to the charms of gaiety, who possess much resource for amusement and occupation in themselves, and who are prepared to make every necessary sacrifice which their condition of health may demand. Wiesen is only eleven miles distant from Davos; hence visitors to the former resort can have their medical wants supplied by the physicians of the latter. Between thirty and forty visitors spent last winter at Wiesen, and the results of treatment are said to have been satisfactory. We are still without definite statistical information on this point. Wiesen is usually approached from Coire, from which it is twenty-four miles distant.

The sanatoria hitherto considered all lie in the same valley, Davos-Dörfli representing its highest and Wiesen its lowest point. I have now to deal with the long famous, and still very important, health-resorts in the Engadine. The valley of the Inn has long been justly celebrated for its magnificent scenery, its mineral waters, and its bracing air. For many years it has been a favourite playground for tourists in the summer and autumn, but it is only since Davos arose into sudden popularity that St. Moritz, Samaden, Pontresina, and the Maloja have put in their claim to rank as winter sanatoria for phthisis. This claim must still be reckoned on its trial, as the results of treatment in the Engadine have hardly hitherto been of a nature to justify the expectation that it will ever supersede Davos. We may safely confine ourselves to the consideration of St. Moritz and the Maloja, as Samaden and Pontresina have grave disadvantages as winter resorts: the former in its windiness; the latter in the contour of the surrounding hills interfering with the sunshine. They have hitherto had few winter residents, and it seems unjustifiable to recommend them when there are several resorts equally accessible and in all respects superior.

St. Moritz enjoys a very charming situation. It is 6089 feet above the level of the sea (nearly 1000 feet higher than Davos), and the village rests on the crest of a hill 300 feet above the level of the Inn valley. Beneath lies a lake, on the edge of which are the baths of St. Moritz (St. Moritz Bad), with numerous splendid hotels, while beyond stretches a range of snowy peaks of great grandeur. The baths have their season in August and September, when St. Moritz is the favourite resort of wealth and fashion, but are closed in winter. Several hotels in the village proper now remain open throughout the year for the benefit of winter visitants, and the accommodation provided is in every way excellent. Good medical attendance can be procured.

A few miles beyond St. Moritz, on the margin of the lake of Sils, is the Grand Kursaal de la Maloja, a magnificent hotel (perhaps the finest in Europe), recently erected. All that money and art can do has been done both to provide for the comfort and to promote the pleasure of winter residents. The scenery in the neighbourhood, though somewhat inferior to St. Moritz, is nevertheless very fine, and a view of the lake with its grand encircling peaks, when the moon rides high and the snow is on the ground, is a scene one cannot easily forget. It must not be forgotten, however, that this fine winter sanatorium is in one of the most secluded positions in Europe. The railway does not approach nearer than Coire on the north, and Chiavenna on the south. There is no village in the vicinity of the hotel, and no opportunity for any social pleasures beyond those afforded by the visitors themselves

What are the climatic peculiarities of the Inn valley, and wherein do they differ meteorologically and in their application to disease from those prevailing in the valley of Davos? St. Moritz and the Maloja are both at a materially higher elevation than Davos; hence they have a lower mean temperature, a longer winter, and a greater duration of frost and snow. Nevertheless, owing to peculiarities of local position, they both enjoy somewhat more sunshine during the winter than Davos, and in this respect the Maloja takes precedence of St. Moritz; but there is one essential point in which, according to the unanimous report of invalids and permanent residents, Davos enjoys an undisputed pre-eminence—namely, stillness of the atmo-

Digitized by Google

sphere. That the Alpine winter climate would be utterly unsuitable to the invalid did not the profound atmospheric calm permit the full influence of the solar heat to be felt while the shade temperature is far below freezing-point is a cardinal and indisputable principle in all theories regarding the efficacy of the high altitude treatment. This point is really the pivot on which the whole question turns. Hence windiness is simply a fatal objection to any *luftkurort*. It would be inaccurate, however, to describe the winter climate of St. Moritz and the Maloja as windy. Perfect days—days of absolute stillness, spotless skies, and uninterrupted sunshine—are by no means rare during winter in the Inn valley, but they are unquestionably less frequent than at Davos. That this must necessarily be so is evident to the eye of any observer who is familiar with the principles which regulate the relation of topography to climate. Just as the waters of the Inn rush down the long funnel-shaped valley of the Engadine, so must there also at times be a descent of atmospheric currents. As the writer drove up from Süs to Samaden on a brilliant day in October, the whistling of the wind reminded him, in spite of the bright sunshine, that he had left behind the atmospheric placidity of Davos. The position of the Maloja hotel, situated almost at the apex of the long double valley formed on one side by the Engadine and on the other by the Maloja Pass and the Via Bregaglia, seems particularly obnoxious to the charge of windiness. The climate of the higher Alps is one of great stimulation and much tonic influence, and these characteristics will be exaggerated in proportion to the amount of wind. But in those cases in which the climate fails to confer benefit, the usual explanation is that it is too stimulating; hence the calm of Davos is all in its favour. At Davos one meets with numerous cases of patients who have crossed over into the Engadine, often for the mere purpose of varying the monotony of existence, but who have been driven back by the over-stimulation of the climate. On the other hand, the results of treatment at St. Moritz and the Maloja have frequently been excellent, but there cannot be a doubt that extreme care is necessary in the selection of cases. Debilitated patients, patients with nervous irritability or the least suspicion of circulatory weakness, should on no account be sent to the Engadine. If Davos and Wiesen are of doubtful applicability to such cases, St. Moritz and the Maloja are absolutely contra-indicated.

The high altitude treatment of phthisis has fought its way into favour against heavy prejudices, and has at least established its claim to careful consideration. It is not a specific, as the rapidly-filling graveyard of Davos abundantly proves, but in properly selected cases its results probably excel those obtained by the older methods. It is to assist the profession in the choice of suitable cases, and to save a hopeful advance in therapeutics from the odium which follows from its improper application, that the present series of articles has been written.

MEDICAL SOCIETY OF LONDON.

GREAT was the success of the Medical Society's Dinner held in the Venetian Chamber of the Holborn Restaurant on Tuesday, Mr. Brudenell Carter, the retiring president, being in the chair. After the loyal toasts had been duly honoured, the toast of "The Army" was responded to by Sir Thomas Crawford, who referred to the question of the "relative rank" of medical officers. His observations entirely supported the position which we took on this question (see THE LANCET, page 482). There was nothing in the Royal Warrant that trenched in any way on the prerogative of the Medical Department of the Army. We have no doubt that the strong assurance of the Director-General of the Army Medical Department will quiet the unnecessary alarm that has been excited. Captain Crozier replied for the Navy, and Colonel Edis for the Volunteer forces. To Mr. T. Bryant was entrusted the toast of "The Houses of Parliament," and this was answered by Colonel Duncan, M.P. Dr. Ord proposed "The Medical Corporations," and Mr. Shillitoe, the Master of the Society of Apothecaries, responded. Sir Joseph Fayrer did the honours of the toast for "The Retiring President." Dr. Hughlings Jackson was warmly received as the new President of the Society. The remarks of Mr. J. H. Morgan, the retiring secretary, Dr. Samuel West the senior secretary, Mr. Bernard Pitts, the new secretary, and Mr. Poole, the much-respected registrar, were received with acclamation. We were greatly pleased with the suggestion of Dr. Samuel West that the clinical meetings of the Society should become a still more prominent feature—a suggestion that we have advocated for some time past as likely to prove of great practical value and interest, and certainly conducive to the welfare of the Association.

THE MANCHESTER MEDICO-ETHICAL ASSOCIATION AND CORONERS' INQUESTS.

AT an ordinary meeting of the Manchester Medico-Ethical Association, held on April 24th, 1885, Dr. Sinclair read a paper upon "Coroners' Inquests." This paper led to the appointment of a sub-committee of the Association for the purpose of obtaining and considering evidence as to the present inefficient working of the Coroner's Court. The sub-committee, with Dr. Sinclair for their chairman and Dr. Owen as secretary, commenced their labours on Sept. 15th, 1885, and held fourteen sittings. Evidence was obtained of the inefficiency of the present system from (1) the personal experience of each member of the sub-committee; (2) from published statements which have appeared from time to time in the medical journals and public papers; (3) from statements received in reply to a circular letter asking for information based upon personal experience. In all 300 letters were addressed to various medical men, including members of the Association, medical officers of health, police surgeons, professed medical jurists, and public analysts. The evidence thus obtained was considered under the following heads: (1) The coroner, his functions, qualifications, and mode of election; (2) the position of medical men as skilled witnesses; (3) the present system of registration of deaths; (4) the coroner's jury. The third branch was found to be inseparable from the inquiry, as much of the inefficiency complained of was found to be due to a faulty system of death registration. After giving a number of cases illustrative of the defects of the present system so far as the coroner is concerned, the sub-committee expressed their opinion: 1. That the qualification and position of a coroner should be those of a stipendiary judge, who should devote the whole of his time to the duties of his office, and that his salary should in no case be dependent upon the number of inquests. 2. That the present mode of election to the office is unsatisfactory, and that the election should invariably rest with the Crown. 3. That the functions of a coroner should be to conduct public inquiries into the cause of death in certain cases by means of the evidence of experts and of other witnesses, and to sum up such evidence in its legal aspects before a properly constituted jury. 4. That he should have no discretion, but to hold an inquest in every case of death, sudden or otherwise, in which the cause of death cannot be certified by a legally qualified medical man. But it is not implied that the coroner should be necessarily debarred from holding an inquiry, provided there exists reasonable grounds for suspicion, because a death has been certified by a legally qualified practitioner. 5. That no inquest shall be held without a previous examination of the body by a properly qualified medical man. After giving details showing the unsatisfactory way in which necropsies are too often made and medical evidence given, the sub-committee made the following suggestions:—1. The examination of the body upon which an inquest is to be held should be made by a medical man specially skilled in such matters, who should be designated the Public Pathologist, and that for every coroner's district there should be one or more such pathologists appointed to conduct the examination of the body previously to the inquest. 2. The appointment of the public pathologist should be made by the same authority as in the case of the coroner. 3. The pathologist should, in cases in which he may deem it necessary, suggest to the coroner the advisability of calling in the aid of other scientific experts (for analysis, &c.). 4. The duties of the public pathologist should not preclude the medical attendant in the case from giving evidence as a skilled witness when necessary. 5. For every coroner's district one or more mortuaries, with proper appliances, should be provided, which would be available for post-mortem examinations in the absence of proper accommodation elsewhere, or in such other circumstances as the coroner might think would

Digitized by Google

warrant the removal of the body; and that the removal of the body to a mortuary should be compulsory under the coroner's order. The report concludes with further suggestions, among them being that registrars of births and deaths should be required to report to the coroner every uncertified death, that the period of medical attendance should be stated in each death certificate, that all still-births should be registered, that the status of coroners' jurors should be improved, and that the present custom of viewing the body is objectionable and unnecessary.

We hope at an early date to take into consideration the views of the sub-committee, which are of a somewhat sweeping character.

SCIENTIFIC RESEARCH.

THE following memorial, signed by medical and surgical teachers of all the London medical schools, has just been presented to the Council of the Royal College of Surgeons:—

To the Council of the Royal College of Surgeons of England.

MR. PRESIDENT AND GENTLEMEN,—We venture to bring to your notice the anxiety that is felt by those who are directly concerned in the teaching of surgery in London with reference to the proposed extension of the buildings in Lincoln's-inn-fields, inasmuch as the present moment offers a unique opportunity for the establishment and endowment of an institute for the advancement of surgery by research.

The progress of surgery largely depends upon the facts obtained by research in the following branches of science: 1. Morbid anatomy, including histology. 2. Experimental pathology, including bacteriology. 3. Experimental operative surgery. The present Museum, which offers a splendid field of study, can never be considered a complete memorial of Hunter's work, and can never be thoroughly utilised for the benefit of surgical science until a laboratory is added to it for the pursuit of the objects above indicated. In view of the increased power and wealth of the Royal College of Surgeons of England, we hold that any Fellow or Member who is competent to carry out scientific investigations should be able to do so without inconvenience and without expense. Within the walls of our own College fresh knowledge would thus be gained, new methods of surgical treatment would be brought to light, and British surgury would no longer be compelled to lean upon the information derived from foreign laboratories for the solution of the many problems which surround its progress. We therefore earnestly hope that in the contemplated enlargement of the College adequate provision will be made for the study of these most important branches of our art.

(Here follow the signatures.)

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Bilston Urban District.—Bilston is one of the urban districts in which some cases of typhus occurred last year, but at the end of December no further cause for apprehending an outbreak of this disease remained. Bilston is, however, a district needing much improvement as regards the lodgment of the people, and this especially as to the vicious practice which formerly obtained of building so-called back-to-back houses. We hope the present bye-laws of the town require every house to have its own appointed open space to the rear. Child mortality causes Dr. T. R. Bailey some anxiety. The rate under one year of age exceeds 180 per 1000 of the children born, but he very much fears that it is largely due to conditions of trade and parental mismanagement, which it will be difficult to overcome. There is, however, room for progress in many matters affecting child life, notably as to the through-ventilation of dwellings and improved means of excrement and refuse disposal. As regards the latter, a change may be hoped for, since the authority are considering an alternative method suggested by Dr. Barry of the Local Government Board.

Ashton-in-Makerfield Urban District.—The general death-rate of this district for 1886 was 17·1 per 1000. The births were 475 in number, and the deaths under one year of age were 64; this gives a rate of 13·5 per cent., which can hardly be regarded as very excessive, but Mr. Hannah evidently thinks it might be further substantially reduced. Especially should the diarrhœa mortality be lessened, due as it largely is, in his opinion, to improper feeding, including the excessive dilution of milk. The general account of nuisances dealt with points to a satisfactory performance of the current duties by the sanitary officers.

Newton-Abbott Combined District.—Mr. Harvey gives the birth- and death-rates of the Newton-Abbott rural district for 1886 as 29·1 and 16·5 per 1000 respectively. In Broadhempstone there were in the early part of the year twelve cases of diphtheria, of which five were fatal. The disease was imported into the local school by children who, for geographical reasons, were allowed to attend the Broadhempstone school, instead of their own in an adjoining district. This circumstance leads Mr. Harvey, as it has led others, to point to the difficulties attending the procuring of information as to outbreaks involving sanitary frontiers. Both this outbreak and a subsequent occurrence of diphtheria led to the discovery, and as far as possible to the remedy, of conditions of filth and of dampness of sites with which the disease was associated. At Kingsteignton the water question was discussed during the year, and Mr. Harvey's description of the sources of contamination in the village, as also of the millions of gallons running through the place continually, convinced the inhabitants of the desirability of securing a proper supply. The first scheme unfortunately broke through, owing to difficulties as to mill-owners' compensation; and now another scheme for securing a spring at Tor Hill is under consideration. At Bishopsteignton a new water-service has been completed, at Bovey new sewers have been laid, at Ashburton new water-works have been commenced, and at Pottery near Bovey and at Fairwater improvements in water-supply have been effected. Indeed, this district has made sanitary progress of a sort which is calculated to improve it very materially, and to give confidence to those who seek a healthy residential neighbourhood. In the *Wolborough* urban district the death-rate was 15·28 per 1000, and the record of work given shows that no opportunity is lost to ensure further improvement in its sanitary circumstances. At *Dawlish* the death-rate was 17·6 per 1000, after making the necessary correction for visitors. Measles and scarlatina prevailed in the last quarter of the year, no epidemic disease having previously existed in the place since 1880. By rigidly excluding children living in infected houses from attending the schools, and by means of other precautions, the diseases appear to have come to an end. During 1886 they each caused three deaths. A difficulty in enforcing a strict bye-law as to the distance of piggeries from houses in the more rural parts of a nominally urban district has arisen in Dawlish. The same has occurred elsewhere, and we believe the Local Government Board now assent either to the division of the district for the purposes of such a bye-law, or else they make the distance clause apply, not to each house separately, but to any two or more houses. The sewerage scheme for Dawlish has again been delayed, and it has been found necessary to prepare new designs by which the sewage may be delivered to the eastward and below low water-mark.

Carlisle Urban District.—Crozier Lodge, the sanitary hospital for this and the rural district, has again served an excellent purpose. The immediate isolation of small-pox in the rural district is held by Mr. William Brown, F.R.C.S., to have saved the spread of infection into the city. Typhus was in a similar way isolated and checked. Carlisle has long been comparatively free from scarlet fever, but there is now an ominous increase of attacks, and seven deaths occurred in 1886. Typhoid fever mortality, though decidedly below the average, showed an increase in 1885, but the causes are carefully ascertained, and, we may assume, also remedied. Diarrhœa was exceptionally fatal in October, 1886, it being associated with an abnormally high temperature for that month. Some important sanitary works were executed during the past year. Extra-mural abattoirs were commenced, the filter-beds of the Carlisle Waterworks were extended, and a portion of the ward accommodation at Crozier Lodge was remodelled and reconstructed. The general mortality for 1886 was at the rate of 19·4 per 1000.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5792 births and 3776 deaths were registered during the week ending March 5th. The annual death-rate in these towns, which had been equal to 19·5, 21·1, and 21·3 per 1000 in the preceding three weeks, was again 21·3 last week. During the first nine weeks of the current quarter the death-rate in these towns averaged 21·9 per 1000, and was 2·3 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 11·6 in Bolton, 14·1 in Brighton, 15·3 in Sunderland, and 17·1 in Birkenhead. The rates in the other towns ranged upwards to 26·5 in Wolverhampton, 26·7 in Huddersfield, 28·1 in Blackburn, and 31·2 in Manchester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had been 340, 371, and 372 in the preceding three weeks, further rose last week to 385; they included 152 from measles, 93 from whooping-cough, 41 from scarlet fever, 34 from diarrhœa, 31 from "fever" (principally enteric), 31 from diphtheria, and 3 from small-pox. These zymotic diseases caused the lowest death-rates during the week in Bolton, Halifax, and Bradford, and the highest rates in Oldham, Manchester, and Huddersfield. The greatest mortality from measles occurred in Liverpool, Salford, Manchester, and Huddersfield; from whooping-cough in Birmingham, Oldham, Preston, and Plymouth; from scarlet fever in Manchester, Salford, and Birkenhead; and from "fever" in Blackburn. The 31 deaths from diphtheria in the twenty-eight towns included 19 in London, 2 in Bristol, and 2 in Birmingham. Small-pox caused 3 deaths in Manchester, but not one in London and its outer ring, or in any of the twenty-six other large provincial towns. Only 6 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had increased in the preceding four weeks from 364 to 466, were last week 459, and were 28 below the corrected average. The causes of 72, or 1·9 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Newcastle-upon-Tyne, Nottingham, Leicester, Portsmouth, and in six other smaller towns. The largest proportions of uncertified deaths were registered in Salford, Oldham, Halifax, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 24·3 and 22·5 per 1000 in the preceding two weeks, rose again to 23·6 in the week ending March 5th; this rate exceeded by 2·3 the mean rate during the same period in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 17·4 in Dundee and 18·7 in Leith, to 25·6 in Glasgow and 32·4 in Aberdeen. The 589 deaths in the eight towns last week showed an increase of 27 upon the number in the preceding week, and included 32 which were referred to whooping-cough, 27 to measles, 19 to scarlet fever, 11 to diarrhœa, 5 to diphtheria, 4 to "fever" (typhus, enteric, or simple), and not one to small-pox; in all, 98 deaths resulted from these principal zymotic diseases, against 103 and 99 in the previous two weeks. These 98 deaths were equal to an annual rate of 3·9 per 1000, which exceeded by 1·7 the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of whooping-cough, which had increased in the preceding five weeks from 19 to 33, rose last week to 32, of which 18 occurred in Glasgow, 5 in Edinburgh, and 5 in Aberdeen. The 27 deaths from measles showed a decline of 3 from the number in the previous week, and included 19 in Aberdeen and 8 in Glasgow. The fatal cases of scarlet fever, which had been 13, 25, and 17 in the previous three weeks, rose again last week to 19, of which 13 occurred in Edinburgh and 4 in Glasgow. The 11 deaths attributed to diarrhœa corresponded with the number in the previous week, and included 5 in Glasgow and 3 in Dundee. Of the 5 deaths from diphtheria, 2 occurred in Glasgow and 2 in Edinburgh; and the 4 deaths referred to "fever" included 2 in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 146 and 121 in the preceding two weeks, rose again last week to 142, but were 38 below the number returned in the corresponding week of last year. The causes of 76, or nearly 13 per cent., of the deaths registered during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 35·3 and 30·7 per 1000 in the preceding two weeks, further declined to 28·1 in the week ending March 5th. During the first nine weeks of the current quarter the death-rate in the city averaged 31·0, the mean rate during the same period being but 20·8 in London and 21·7 in Edinburgh. The 190 deaths in Dublin last week showed a further decline of 18 from the numbers in the previous two weeks; they included 7 which were referred to scarlet fever, 5 to "fever" (typhus, enteric, or simple), 1 to measles, 1 to whooping-cough, and 1 to diarrhœa. Thus the deaths from these principal zymotic diseases, which had been 14 in each of the preceding two weeks, were last week 15; they were equal to an annual rate of 2·2 per 1000, the rates from the same diseases being 1·6 in London and 4·2 in Edinburgh. The deaths from scarlet fever, which had been but 3 and 2 in the previous two weeks, rose last week to 7; the 5 fatal cases of "fever," on the other hand, showed a decline of 3 from the number in the previous week. The deaths of infants showed an increase of 3, and those of elderly persons a decline of 2, compared with the numbers in the previous week. Four inquest cases and only one death from violence were registered; and 40, or nearly a quarter, of the deaths occurred in public institutions. The causes of 29, or more than 15 per cent., of the deaths registered during the week were not certified.

THE SERVICES.

A SPECIAL COMMITTEE, composed of Sir Archibald Alison (who is to preside), Sir Evelyn Wood, Mr. G. Lawson, Sir Thomas Crawford, and Colonel Methuen, has been appointed to consider the full organisation of the medical department for an army corps in the field, as well as the number of horses and servants required for medical officers on active service.

WAR OFFICE.—Army Medical Staff: The date from which Surgeon-Major S. Moore, M.B., is granted retired pay, with the honorary rank of Brigade Surgeon, is Jan. 22nd, 1887, and not, as stated in the *Gazette*, February 11th, 1887. The undermentioned Surgeons on probation to be Surgeons:—F. J. Morgan; W. H. Horrocks, M.B.; C. H. Hale; H. C. Thurston; B. H. Scott; W. C. Poole, M.B.; O. R. A. Julian; G. Raymond, M.B.; E. A. Burnside; T. McCulloch, M.B.; A. B. Hinde; A. Y. Reily, M.B.; J. W. Cockerill; J. Ritchie, M.B.; H. St. G. S. Hore; S. Macdonald, M.B.; E. Corcoran; A. O. C. Watson, M.B.; E. W. Gray, M.B.; D. Stiell, M.B.; L. E. A. Salmon; G. A. Wade, M.B.; J. Minniece, M.D.; R. H. Penton; M. P. C. Holt; W. L. Gray, M.B.; E. G. Browne; J. C. Morgan; H. I. Pocock; G. Hilliard, M.B.; C. R. Elliott, M.D.; C. A. Young; J. W. Bullen, M.D.; J. C. Weir, M.B.; B. J. Innis; R. C. Thacker; W. N. Murphy, M.D.; S. F. Clark, M.B.; and E. M. Hassard.

ADMIRALTY.—The following appointments have been made:—Surgeon John Lownes, to the *Landrail*, to date from the 10th inst.; Staff-Surgeon J. Lyon, to the *Ajax*; Surgeon G. A. Spiller, to the *Duke of Wellington*, additional, for disposal; Surgeon W. C. Spiller, to the *Ganges*, additional, for disposal; Surgeon W. Belt, to the *St. Vincent*, additional, for disposal; Surgeon H. W. Rickards, to the *Boscawen*, additional, for disposal; Surgeon F. W. Brice, to the *Britannia*, additional, for disposal; Surgeon J. W. Slaughter, to the *Cambridge*, additional, for disposal; Surgeon J. B. Clibborn, to the Lisbon Hospital, to date from 11th inst.; Surgeon S. D. O'Grady, to the *Indus*; and Surgeon C. J. Mansfield, to the *Griffon*, to date from 16th inst.

The following qualified candidates for the Naval Medical Service have been appointed to be Surgeons in Her Majesty's Fleet:—John Douglas Hughes; William John Colborne; John Hutton Stenhouse, M.B.; Joseph Agnew Moon; Robert Hardie, M.B.; Cornelius Bradley, M.D.; George Trevor Collingwood; Richard Miller, M.B.; George Fletcher Collins; Charles Dickinson; John Edwin Coad, M.B.; Hubert Holyoake; George Wilson, M.B.; James Moore; Edwin Griffin, M.D.; John Duncan Menzies, M.B.; Hugh St. David Griffiths; and Walter Bowden.

In accordance with the provisions of Her Majesty's Order

Digitized by Google

in Council of April 1st, 1881, Fleet-Surgeon Robert Nelson has been placed on the Retired List of his rank.

RIFLE VOLUNTEERS.—5th Durham: Andrew Arthur Abraham, Gent., to be Acting Surgeon.—2nd Volunteer Battalion, the Gloucestershire Regiment: Surgeon Thomas Partridge is granted the honorary rank of Surgeon-Major.—1st Volunteer Battalion, the Lancashire Fusiliers: Surgeon J. E. Lees, M.B., resigns his commission.—3rd Volunteer Battalion, the Northumberland Fusiliers: Surgeon Anthony Bell is granted the honorary rank of Surgeon-Major.

Correspondence.

"Audi alteram partem."

THE TREATMENT OF PLACENTA PRÆVIA.

To the Editors of THE LANCET.

SIRS,—An *ex cathedrâ* statement in THE LANCET on the treatment of placenta prævia carries such weight with the profession, both at home and abroad, that I am anxious to be permitted to point out that, so far, it is only in Germany that such exceptionally good results have been obtained by the method of Braxton Hicks (bipolar version), which is the treatment recommended so forcibly in its columns of to-day. Lomer, on page 1235 of the *American Journal of Obstetrics for* 1884, gives the following table—

	Cases.	Mothers died.	Children died.
Hofmeier ...	37	1	23
Behm	40	0	31
Lomer	101	7	51
	178	8	105

It follows, then, that since these three obstetricians must have treated fifty-eight cases without a death, unless the number 236 mentioned in THE LANCET is a misprint; and, as fifty-eight is also the number of cases which Behm is reported to have treated without a death, the coincidence is so remarkable as to suggest the possibility of an error in the number. In this country and in America the method of Barnes (partial separation of the placenta and cervical dilatation with hydrostatic bags) has given such very good results that the time has not yet arrived to definitely settle which is the best mode of treatment, though to my mind either is incomparably better than any other method hitherto suggested. And to show that some of our continental brethren appreciate our work, I would refer your readers to the "Thèse d'Agrégation" (accouchements) for 1886, entitled "De la Conduite à tenir dans les Cas de Placenta Prævia," by Dr. A. Auvard,[1] who, in addition to Budin (now happily restored to health by the skill of our countryman, Lawson Tait), promises to worthily uphold the high prestige of the French obstetrical school. In this work the author discusses several methods of treatment, but places the two English methods in the first rank, and enters fully into their respective merits, arriving at the conclusion that both "sont donc également bonnes" (page 145); and on page 72 he is kind enough to say, "Les résultats obtenus par Murphy à l'aide de la méthode de Barnes sont excellents"; and on page 144 that in my hands this method "est celle qui s'offre avec les chiffres les plus brillants."

I have now treated twenty-eight cases of placenta prævia without a single death, twenty-three of which are recorded in the *Medical Press and Circular* for 1885, pages 179-205; and as I have obtained such good results from the method of Barnes I naturally prefer it, more especially as the hydrostatic bags are required for what I would wish to enunciate as a ninth great proposition—"that premature labour should be brought on as soon as we know that we are dealing with a case in which the placenta presents after the seventh month of pregnancy, and even before then should the bleedings be serious, frequent, or continuous." This rule I have urged as strongly as I could in the paper referred to, I have always acted on it, and it is only by continning to do so that I can hope to keep my mortality at *nil*, or even at a small percentage. For what can a man do when called to a case already *in articulo mortis*? And it should be constantly borne in mind that hæmorrhage may occur at any time during pregnancy, and that it must occur when labour sets in; and we cannot foresee when it will take place or in what quantity it will pour out; and it may be, and often is, so sudden and so copious that death occurs before assistance can be obtained; or that the patient is so exhausted that assistance, when it comes, is powerless to save life. And I would impress upon your readers that the horrible mortality of placenta prævia is not due to the impotence of our art, but to violent hæmorrhage occurring before assistance can be obtained, or where that assistance is of a helpless, do-nothing character. Whereas, if we take warning from the preliminary bleedings (which often are slight at first), we can generally have time to fix a convenient opportunity to be present during the whole period of labour, ready for every emergency, and, thanks to Barnes's bags (or Steele's, as I prefer), we can fix the time for inducing labour as easily as for doing an abdominal section; and labour can be surely and safely brought on and completed, as I have demonstrated over and over again, in some cases even in a shorter period than it takes for a complicated ovariotomy. Another great advantage this method possesses is, that it enables practitioners who have no particular *penchant* for obstetrical operations to secure the help of an obstetrician with practical experience of placenta prævia to aid them, and to share the responsibility in this the most terrible complication of labour.

I am, Sirs, yours obediently,

Sunderland, March 5th, 1887. JAMES MURPHY.

[1] Octave Doin, 8, Place de l'Odéon, Paris.

THE NATURE OF COMA.

To the Editors of THE LANCET.

SIRS,—I have been much interested by the leading article on Coma in your last issue. You quote Dr. Hughlings Jackson, that "the breathing fails before the heart, and the accessory parts of the breathing fail before the fundamental. It consists in a long process of degradation, the last point of attack being the heart, and the penultimate the breathing." I have recently had a case where, on the night preceding death, the pulse frequently disappeared, while the breathing was loud and stertorous. Soon after 8.30 A.M. it stopped altogether, and the heart's action could not be detected, but this may have been due to the presence of loud râles in the lungs. The breathing continued noisy, and at the rate of 23 to the minute, till it gradually fell to 17, and then ceased at 2.30 P.M. During the whole time, frequent examinations were made to see if the heart's action could be observed, but without success. I conclude from your article that it must, however, have continued working all this time. The patient was seen in consultation during the "precomatose period" by Dr. Broadbent, Mr. Walter Coulson, and Dr. Russell Reynolds.

I am, Sirs, yours truly,

J. B. EMMERSON, M.D. Durham.

High-street, Biggleswade, March 7th, 1887.

NORTHERN COUNTIES NOTES.

(*From our own Correspondent.*)

NEWCASTLE INFIRMARY: ADOPTION OF THE FREE HOSPITAL SCHEME.

AT a special meeting of the governors of the Newcastle Infirmary, it was decided, in deference to the house committee and medical board, to adopt their report, and make the infirmary a free hospital, subject to a reservation of existing rights of life governors and to the receipt of periodical contributions from the workmen of Tyneside. It was shown by the report that the average cost to the infirmary of each in-patient had been £4 5*s*. 6*d*., or £2 3*s*. 6*d*. more than paid for each letter of admission. With regard to the recommendation to discontinue the admission of children, the committee thought it was premature to commit themselves to its adoption. The committee did not adopt the recommendation to admit paying patients, but steps were to be taken to see that each in-patient, when able, contributed in whole or part to the expense of their maintenance. They recommended that the casual department be remodelled and the out-patient department be confined to such cases as had

Digitized by Google

already received treatment in the wards; also, that the rule excluding male venereal cases from the hospital be strictly enforced. As regards the suggested fee to be paid by medical students, this proposal has been considerably modified. As now fixed, the fee to be paid by all students at the infirmary will be six guineas perpetual, and for one year two guineas. The original proposition was £5 5s. per annum. With regard to the election of the honorary staff, in the future the mode of election is to be altered so as to avoid the expense of canvassing, and for this purpose a committee of selection is to be formed, taking care that it is sufficiently numerous and of a representative character. When this important report was put to the meeting it was quietly and unanimously carried; and so the week has seen a great organic change in our infirmary, by which I predict it will be ultimately benefited, although at first some interests may suffer, and the sudden change will no doubt give rise to some confusion in the house, which will, however, soon adjust itself to its altered constitution.

Newcastle-on-Tyne, March 7th.

EDINBURGH.

(From our own Correspondent.)

PROFESSOR RUTHERFORD'S RETIREMENT.

DR. WILLIAM RUTHERFORD, Professor of Physiology in the University, has retired from his chair on leave of absence. The plea upon which his absence is permitted from the duties of his department is, as stated in the local papers, one of ill-health, produced by overstrain and worry. It is known to the public that the unfortunate matter connected with his misunderstanding with his late senior assistant is now receiving the attention of the University Court, as suggested in a recent issue of THE LANCET. The arrangements for carrying on the work of the summer session are not yet finally settled, but at the approaching professional examinations Dr. Caton of Liverpool has been appointed to take Professor Rutherford's place.

UNIVERSITY BUILDING FUND.

The Chancellor of the Exchequer has met the wishes of the University authorities in respect to the Government grant towards the cost of the site for the completion of the medical buildings. The sum of £8000 is to be granted by Government, and the remaining amount (£4000) necessary to effect the purchase is contributed by the munificent donor, who has already presented the funds for the building itself. The last difficulty in the way is thus removed, and the work will at once proceed.

MEDICO-CHIRURGICAL SOCIETY.

An animated discussion upon the diagnosis and treatment of cerebral abscess occupied the whole of the last meeting of the Society. The subject was introduced by Dr. M'Bride and Mr. A. G. Miller in a joint paper upon those cases of abscess which follow ear disease. Dr. M'Bride's part of the paper was a complete and exhaustive exposition of the whole subject, containing many new observations of great practical importance. Among these are his views upon the value of the tuning-fork as an aid to the localisation of the abscess. If the vibrations be perceived by the injured ear on contact of the tuning-fork with the cranial bones, it indicates that the internal ear is intact, that the middle ear is the part affected, and that the abscess is situated above the tentorium. Should the vibrations not be perceptible, the internal ear is affected, in which case the matter is usually below the tentorium, in the cerebellum. His differentiation of cerebral abscess from purulent meningitis and from phlebitis of the lateral sinus was another point of great importance. The operation proposed in such cases by Dr. M'Bride, and carried out by Mr. Miller, is to cut down as near as possible to the source from which the pus has sprung—i.e., by the nearest route to expose the roof of the tympanum. This is done by reflecting the pinna downwards, opening the skull by means of a chisel at a point a quarter of an inch above the osseous meatus, at which point the bone is exceptionally thin and can be perforated with great ease. This incision opens into the cranium exactly at the floor of the middle fossa. The dura mater is then raised from the petrous portion for a third of an inch towards the middle line, and the roof of the tympanum thus exposed, any abscess in connexion with it being opened; or, if contiguous but not continuous, the abscess may be evacuated by incising the dura mater and a portion of the brain substance. Mr. Miller read the notes of the cases operated on, and made some remarks on the surgical aspects of the subject. He spoke of the importance of differentiating cerebral abscess from purulent meningitis, the temperature being taken as the most crucial symptom in doing so: in the former, he thought an operation was indicated; in the latter, experience showed it to be of little avail. Professor Greenfield and Professor Annandale spoke on the subject: the former referring to his recent case, in which Mr. Caird had evacuated an abscess in the temporo-sphenoidal lobe, with a satisfactory result; the latter discussing the plea for operative interference in such cases, in cerebellar abscess, and in cognate conditions in the skull. Dr. Byrom Bramwell contributed some important factors to the discussion by his clear statement of the grounds on which a diagnosis of cerebral abscess can be clearly established. Mr. Caird discussed the best site for operation in such cases. Prof. Chiene and Dr. Hughes Bennett also spoke, the latter referring to the success of trephining, with removal of a portion of skull and membranes, in cases of ordinary epilepsy.

DUBLIN.

(From our own Correspondent.)

ROYAL COLLEGE OF SURGEONS.

BY a majority of 12 to 3 the Council of the Royal College of Surgeons have passed a resolution in which the views of the College of Physicians were invited on the subject of the admission of the Apothecaries' Hall into the proposed conjoint scheme between the two Colleges. The Council declare that two alternatives seem to be open—namely, a combination between the three bodies, or a combination between the Colleges of Surgeons and Physicians on the one hand, and the College of Surgeons and the Apothecaries' Hall on the other. This latter is the dual scheme proposed by Sir Charles Cameron, but the Council prefer the former arrangement. The College of Physicians have had this resolution before them, and have again, by a nearly unanimous vote—I believe the numbers were 19 to 2—declared against the tripartite scheme. I have reason, however, to believe that many of the Fellows of the College of Physicians are not adverse to the proposal to allow the College of Surgeons to be allied with the College of Physicians, and also to form a combination with the Apothecaries' Hall. It is felt by the great majority of the profession in Dublin that almost any scheme would be preferable to that which would allow the Apothecaries' Hall to be a complete licensing body. The interests of the students should also be considered, and until some definite scheme becomes adopted their position is a very anxious one, not knowing for certain what subjects they will be examined in, or what regulations they must obey so as to qualify themselves for examination.

DIPLOMA IN PUBLIC HEALTH.

As mentioned in last week's issue, the Council of the Royal College of Surgeons have agreed upon a scheme for the institution of a diploma in public health, and have submitted the same to the General Medical Council for approval. The examination will extend over three days, and will include the usual hygienic subjects. The fee has been fixed at seven guineas, to both those who hold diplomas of the College and those who do not. It is expected that many army surgeons will apply for the diploma, and it is understood that the examination will be of such a nature as to raise the character of the diploma as high as possible.

RARE FORM OF DOUBLE VAGINA.

At a meeting of the Obstetrical Section of the Academy of Medicine in Ireland last week, Dr. William Fraser described an example of a double vagina which had come under his observation in a lady patient. The septum was only about an inch and a half in length, thus differing from the ordinary cases of double vagina.

LIMERICK DISTRICT LUNATIC ASYLUM.

The Limerick Town Council recently refused to pass a presentment with regard to the maintenance of this

Digitized by Google

institution, on the ground that they were not properly represented on the board of governors. Last week, however, at the Limerick Spring Assizes, before Mr. Justice O'Brien, an application was made for the amount required, and without hesitation his lordship fiated the presentment.

Charles Hudson, F.R.C.S.I., died on the 3rd inst., at Glenville, county Cork, aged eighty-five years.

Dublin, March 8th.

BELFAST.

(From our own Correspondent.)

THE ROYAL HOSPITAL.

FROM the report presented at the quarterly meeting on March 1st, we gather that there have been during the past three months 594 in- and 2652 out-patients. The financial condition of the hospital is now very satisfactory. At the close of the last quarterly report the debt due by the hospital was £1542 3*s*. Through the kindness of friends, a number of large contributions have been made, and the debt is now wiped out. Further, a bequest amounting to £3015 12*s*. 6*d*. has also been received, and the sum of £3000 has been invested on behalf of the hospital. There has been a slight falling off in receipts, but an active and extensive canvass for new and enlarged contributions is now being prosecuted by a number of influential citizens of the town, and by this means the Board hope that a much-needed and solid addition to the permanent income of the hospital will be realised. One of the most active and respected members of the Board of Management made a strong appeal to those present to associate the Queen's Jubilee with the establishment of a consumption hospital in Belfast, where it is said more than 700 persons die annually of phthisis. A movement in this direction has already been made by Mr. Foster Green, as announced in your issue of last week. In addition, other friends have promised contributions sufficient to bring the amount up to £5000. It is hoped the remaining sum will soon be forthcoming.

THE BELFAST HOSPITAL FOR SICK CHILDREN.

At a numerously attended meeting of the friends of this institution the following resolution was unanimously passed: "That the committee and friends of the Belfast Hospital for Sick Children have for many years past felt the necessity of having a convalescent home in connexion with it, and they believe no more desirable object could be selected to form a memorial of the Queen's Jubilee." Further, the meeting pledged itself to endeavour to have a cottage convalescent home founded this year, with the hope of its future extension. The building of such a convalescent home would render the Children's Hospital complete in every respect.

BIRTH OF TRIPLETS.

The Royal Bounty (£3) has been forwarded to a poor woman in Belfast, who was recently delivered of three daughters, all of whom are living. On Saturday night last, another poor woman in the Belfast Union Infirmary gave birth to one boy and two girls, all of whom are alive.

Belfast, March 8th.

THE SEWERS OF MONACO.

(From our Special Correspondent.)

IN no part of the Riviera are greater cleanliness and order maintained than at Monaco. The little Principality is a small paradise by reason of its unequalled climate and beauty; but, so far as sanitation is concerned, and theoretically speaking, it is not more advanced than the neighbouring French health-resorts. Practically, there is a great improvement. For instance, the French rule is that cesspools should not overflow into sewers, that they should be ventilated on the roof of the houses, and frequently emptied. These principles are strictly observed at Monaco, and very generally neglected elsewhere, and notably at Nice. Again, the scavenging of Monaco is done with such care that it would be difficult all Europe to find a cleaner place. Unfortunately the authorities are altogether behind the age in their knowledge of sanitation. They have sought no better example than what is done in Paris; and in this respect the French are notoriously half a century behind the age. With regard to the theory of sanitation, the authorities of Cannes are far ahead of the Government of Monaco. They, at least, have studied the progress realised in England, America, and Belgium. They have consulted such eminent men as Mr. Douglas Galton and Mr. Isaac Shone, and now actually propose to adopt the Memphis or Warring system of drainage. At Monaco, however, the authorities have scarcely got beyond the precepts laid down by the French administration of the Ponts et Chaussées. As the Principality is quite independent of the control exercised throughout France by this official and somewhat inert body, better things might have been expected. Nevertheless, there is, especially on the part of the Prince of Monaco, an earnest desire to do all that can in reason be accomplished to assure the material prosperity of all who live within his domains. The Crown Prince, it should also be noted, is especially fond of scientific studies, and the experiments which he has recently and successfully accomplished to test ocean currents have brought his name prominently forward. Doubtless the Prince would also appreciate the practical utility and the theoretic interest of sanitary science if these questions could be brought more prominently to his notice.

The desire to encourage sanitary improvements is sufficiently manifest. The large sums of money already spent on such purposes, and the marvellous cleanliness maintained throughout the Principality, supply ample proof of this most commendable disposition. Unfortunately, there is an absence of scientific thoroughness in the work done. Slight epidemics of diphtheria, small-pox, and typhoid fever have constantly afflicted the inhabitants of the Principality. At last, in 1883, the recurrence of these illnesses assumed alarming proportions. An epidemic of typhoid fever broke out in the old town of Monaco. Out of the 1200 persons who live on this picturesque and historic rock some 300 inhabitants were stricken by the fever. Fortunately the disease manifested itself in a mild form, as there were only twenty deaths. The epidemic was no sooner over than the authorities sought to improve the sanitary condition of the old town, first by augmenting the water-supply, and secondly by building sewers. This latter operation presented exceptional difficulties, for the town is built on solid, hard rock. At one point, the square in front of the Palace, it was necessary to hew down in the rock to a depth of six yards, so as to obtain the necessary fall. Blasting powder had to be employed, and the sewers consequently cost much more than usual. They were built on the ordinary French model. They are of the egg shape and measure some 70 centimetres by 50 centimetres, and other and larger sewers measure 1·40 metres by 80 centimetres, and 40 centimetres at the lower part or invert. The minimum fall is 15 millimetres per metre; in some parts it is equal to 20 millimetres.

It is, however, obvious that the mere building of a sewer does not solve the problem. The sewer may be admirably constructed, but it may be too large or too small for the amount of sewage that it is destined to receive. The fall also may be too steep, as well as not steep enough. But in France these considerations are rarely taken into account. The idea that a sewer should be self-cleansing is so little realised that the authorities always insist that a sewer should be large enough to allow of a man to go down and clean it. Now, at Monaco a very large sum of money has been spent to build very fine sewers; but there is no water to flush them, no provision made for their ventilation, and no regulations issued to prevent the gases they generate from entering the houses. The closets are not drained into these sewers. The difficulty, therefore, of dealing with the closets and of removing the night soil still remains unsolved, and it was scarcely worth while incurring the expense of building the sewers. But the kitchen water, washing water, &c., do drain into the sewers; and therefore—a fact which has been demonstrated over and over again, and will be found recorded in every text-book—the sewers are just as foul as if they did receive the contents of the closet. Indeed, anyone who has had any practical experience of the difficulties of drainage will testify that it is the grease in the kitchen water, the odours of the vegetable and fish water, that create by far the most nuisance and the most trouble.

As at present managed, the new sewers at Monaco must

Digitized by Google

seriously endanger the health of the population. The kitchen sinks, generally in a back room, but within the houses, drain straight into the sewer. None of them are trapped. They are simply so many sewer ventilators; and, as the sewers are not flushed, and are not self-cleansing, it may readily be imagined with what effect these pipes poison the atmosphere within the houses. It is only necessary to hold a wax taper to the orifice to note how strong is the draught that travels up and down. But to these criticisms the objection may be raised that the health of Monaco has improved. Dr. Colignon, in an eloquent and able paper read at the sixth International Pharmaceutical and Chemical Congress, estimated the death-rate for the five years from 1874 to 1879 at one death per annum per 47·3 inhabitants; while during the following five years, from 1879 to 1884, the death-rate had decreased to one death per 49·9 inhabitants. But these data are not sufficiently recent to throw much light on the subject; and the improvement on the public health, such as it may be, is undoubtedly due to the great increase and the purer quality of the water-supply, rather than to sewers which are certainly not yet in working order. It would, however, be a matter of no great difficulty to improve and complete these sewers, so that, instead of being a source of mischief, they would help to preserve the public health. No act of legislature, no increased powers, are necessary to send an inspector round to all the houses, and insist on the application of a syphon trap to every pipe communicating with the sewer. Even if these traps were inserted at the expense of the State, and not of the individual householders or tenants, the outlay would be very trivial as compared with the cost already incurred in building the sewers. While this is being done, the water of the fountains, now wastefully allowed to flow into the sea by surface gutters, should be utilised to fill automatic flush tanks, which every hour or so would discharge several cubic metres of water into the sewers. With the assistance of automatic flushing tanks there is water enough at hand to sweep the sewers and maintain a fair degree of cleanliness. Finally, it will be necessary to find some effective means of relieving the pressure of air in the sewers, and when this has been done there will remain no reason why the closets should not also drain into them. The outfall is in the deep water of the sea at the extremity of the rock. Some objection may be raised to draining into the sea; but this is what is actually done, only in an extremely clumsy and dangerous manner. The contents of the cesspool and of the pails are at the present moment conveyed by hand or in carts to the sea and emptied into it. There is no sewage farm and no sewage works. Why not, therefore, drain at once into the sea, instead of allowing highly dangerous organic matter to accumulate, decompose, and ferment in tubs, pails, and cesspools, built or kept under and within human habitations?

By following these simple and inexpensive suggestions, the very considerable work done in the old town of Monaco will not have been undertaken in vain. The Principality will then have the honour of setting an excellent example to the whole Riviera, and the Monegasque population will surely enjoy the advantage of a marked amelioration in health and freedom from zymotic disease.

Monaco.

*** The above letter has been in our hands for some weeks, and kept out of our columns by the claims of other more pressing matter. It therefore deals with the state of things existing before the recent telluric convulsions which have more or less included Monaco in its devastating effects. —ED. L.

MEDICAL NOTES IN PARLIAMENT.

The Lunacy Laws Consolidation Bill.

IN the House of Commons on the 3rd inst. Mr. Salt asked the First Lord of the Treasury whether it was proposed to incorporate the Idiots Act, 1886, in the Lunacy Laws Consolidation Bill of the present session. Mr. W. H. Smith replied that the subject had been brought under the attention of the Lord Chancellor by the Lunacy Commissioners, and the matter is now under consideration. It would, however, be premature to arrive at any conclusion on the subject before the Amendment Bill (on which the Consolidation depends) has made further progress, and the question is, Mr. Smith remarked, the more important because the legislation with reference to idiots was deliberately severed from the Bills relating to lunatics in the last Parliament.

The Vaccination Acts.

On the 4th inst., in reply to Sir C. Russell, Mr. Ritchie stated that the reason he had given for refusing the appointment of a Royal Commission of Inquiry into the vaccination question was that the Government already possessed accurate information upon the subject, and that if they consented to the appointment of a commission of inquiry, they did not believe that it would have the least effect in removing the objection of those who at present resisted the law, while, on the other hand, it might have the effect of implying doubts on the part of the Government which the Government did not feel in the slightest degree.

On the 8th inst., in answer to Mr. Picton, Mr. Matthews briefly reviewed the case of a man named Bamford who was convicted last month of non-compliance with the Vaccination Acts, and stated that he did not see his way to modify the prison treatment of a person who has disobeyed the law on the ground that such disobedience proceeded from conscientious motives, the *bona fides* of which it would be difficult to ascertain.

Post Office Medical Officers.

On the 4th inst., in reply to Mr. Pickersgill, Mr. Raikes stated that the practice in appointing medical officers attached to post offices has been, as he understood, to submit to the Postmaster-General the names of several medical gentlemen recommended by the local officers, and one of these gentlemen has usually been formally recommended by the Secretary. But the Postmaster-General has always exercised his own judgment in making the appointment. There was no ground for suggesting that the Secretary's recommendation had been slighted in any case where he had made an appointment upon other local information.

Rivers Pollution Prevention Act (1876) Amendment Bill.

On the motion of Mr. Thorburn, leave was given to bring in a Bill to amend the Rivers Pollution Act (1876), and the Bill was subsequently brought in and read a first time.

Accommodation for Prisoners awaiting Trial.

On the 7th inst. Sir John Kennaway gave notice that on Monday next he will ask the Secretary of State for the Home Department what steps the Government intend to take to deal with the evils shown to exist by the report of the Committee on the accommodation of Court-houses and other places for prisoners awaiting trial at assizes and sessions.

The Lunacy Laws.

On Thursday in the House of Lords the report of amendments on the Lunacy Laws was received and considered. The Lord Chancellor said his amendment of Sub-section 11 sought to give an alleged lunatic the right to be examined by the County Court judge or magistrate before an order for his removal to an asylum is made. Lord Herschell pointed out that there might be a difficulty in respect of the ability of the judge or magistrate to examine the person within the time specified by the Bill.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT an ordinary meeting of the Council held on Thursday last, Mr. H. G. Howse was admitted a member of the Court of Examiners. A report from the Committee on the forms of the College diplomas was approved and adopted, and these will be issued directly by the Council instead of by the Court of Examiners as formerly.

It was agreed, in the report of the President and Vice-Presidents, "That the offer of Mr. J. T. Morton for the institution of a Lectureship on Cancer and Cancerous Diseases, for the period of three years, as an experiment, be accepted; and that there should be one lecture on the subject delivered in each year."

The subject of the form of the new Charter having been mentioned to the Council, and the difficulties in giving effect to the resolution of the Council, admitting Members of fifteen years' standing to the fellowship without examination in anatomy and physiology, having been pointed out to them, the Council rescinded their resolution.

It was agreed to accept the recommendation of the

Digitized by Google

delegates as to the best mode of celebrating the Queen's Jubilee, and to place a statue of Her Majesty in the new Examination Hall.

A letter was read from the Conjoined Associations of Fellows and Members declining to meet the delegates of the Council on the terms required by that body.

A communication was received from the Association of General Practitioners requesting a conference with the Council, and it was agreed that the President and Vice-Presidents should receive a deputation from the Association, the latter to define the subject of the proposed discussion. A communication was also received from Sir F. Abel asking the Council to bring the proposed Imperial Institute under the notice of the Fellows and Members of the College.

A report from Mr. Marshall on the proceedings of the General Medical Council was read.

A letter from the President of the Medical Council was read, asking the Council of the College to reconsider their determination regarding the non-admission of the Apothecaries' Society to the conjoint examinations. This was postponed to an extraordinary meeting of the Council to be held on the 24th of this month.

A memorial was read from teachers of surgery in London, and referred to the Committee on the Extension of the College Premises.

A communication from University College, Bristol, asking that the degrees of the Royal College of Physicians and the Royal College of Surgeons should not be reserved for students who have pursued their clinical studies in London only, was referred to the committee of delegates of the two Colleges.

Obituary.

NICOLA GASPARRI.

FEW situations in modern warfare have evoked greater heroism than the stand made by the Italian column under Col. di Cristoforis against the thousands of Abyssinians who hemmed them in at Dogali. When man by man the European force of five hundred had fallen till only twelve, including the brave colonel himself, remained to continue, in spite of wounds, the unequal combat, Di Cristoforis ordered the eleven to present arms to their fallen comrades. He was obeyed, but in a few minutes thereafter he was struck down, and the others with him. Just before this fine act of disciplined heroism, there had fallen Dr. Nicola Gasparri, fighting like the rest, though he was the surgeon attached to the column. He was but in his thirty-third year, and had already given proof of high professional ability. He was born in Rome, though his family were from the Marches—on the father's side natives of Urbisaglia. Left an orphan before his teens, he was educated by two maternal uncles, one of whom, Prof. Cozzi of the University of Urbino and mayor of that town, adopted him as his son. At the University of Macerata his studies were prosecuted under the happiest auspices; and when he left it a graduate in Medicine and Surgery in 1876, he carried with him the admiration and affection of all his fellow-students. In compliance with his earnest wish he became an army medical officer, and by the time he had reached his thirty-third year he had risen to be medical captain attached to the 15th Regiment of Infantry. A pleasant episode in his career was the journey he made through India with the distinguished physician Dr. Paul Mantegazza, after which very active service awaited him. He was at his own request transferred to Massowah, and a few days before the fatal march on Dogali he had written to his uncle, Prof. Cozzi, at Urbino, in the gayest mood, asking how he thought the carnival was to go off, telling him of the advance of the Abyssinian chief, Ras Alula, and adding, "we hope in carnival week to pepper Ras Alula with the *coriandoli* [comfits] of our Wetterly rifles." This letter was dated January 21st, and on the 26th occurred the terrible encounter in which its writer met a hero's death. It is believed that Dr. Gasparri, on hearing of Col. di Cristoforis's contemplated march to relieve the garrison at Saati, asked, and obtained leave, to join the column.

A NEW semi-convalescent home in connexion with the Leeds Infirmary is about to be erected at Cookridge, at a cost of about £5000.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen, having passed the necessary examinations, were admitted Licentiates in Dental Surgery at a meeting of the Board of Examiners on Feb. 24th:—

Buckley, Charles Herbert, Shaw-road, Oldham.
Clifford, Isidore, Grosvenor-street.
Cunningham, George, King's-parade, Cambridge.
Dalby, Alfred Burkett, Rodney-street, Liverpool.
McAlpin, Kenneth Wade, Tregunter-road, South Kensington.
Thomson, Archibald Frederick Charles, Guilford-street, Russell-square.
Harris, Percy Reeves Traer, M.R.C.S., Chapel-street, Penzance, Cornwall.

Professor Charles Stewart, M.R.C.S., commenced on Wednesday, the 9th inst., a course of nine lectures on "The Auditory Organs of the Vertebrata," and on "Some Recent Additions to the Museum," which will be continued on Fridays, Mondays, and Wednesdays, March 11th, 14th, 16th, 18th, 21st, 23rd, 25th, and 28th. The lectures will be delivered in the theatre of the College at 4 o'clock each day.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise on March 3rd:—

Bullock, Roger, M.R.C.S., East Gate, Warwick.
Deacon, George Edward, M.R.C.S., Hethersett, Norfolk.
Fischer, William Featon, M.R.C.S., Bembridge, Isle of Wight.
Gowan, Bowie Campbell, Gloucester-road, South Kensington.
Hubbard, Walter Lovett, The Grove, Clapham-road.
Williams, William, Esgair Gawr, Dolgelly, Wales.

VACCINATION GRANT. — Mr. John Hamilton, of Swadlincote, has received, for the fifth time, a Government gratuity for efficient vaccination in the Church Gresley district of the Burton-on-Trent Union.

ON the 4th inst. a public meeting in aid of the funds of the East London Hospital for Children and Dispensary for Women, at Shadwell, was held at the Mansion House, under the presidency of the Lord Mayor.

AT the annual meeting of the directors of and subscribers to the Paisley Infirmary, on the 1st inst., an unsatisfactory financial report was presented, the debt having increased during the year from £161 to £693.

WESTMINSTER HOSPITAL.—Shortly after Easter two performances will be given at the Novelty Theatre in aid of the fund which is now being raised for the endowment of a children's ward in this institution.

AT the annual meeting of the subscribers to the Monmouth Hospital and Dispensary on the 1st inst., a highly satisfactory financial report for the past year was presented and adopted.

FOUR CHILDREN AT A BIRTH. — A woman named Corrigan, living in the County Leitrim, was last week delivered of four children, three girls and a boy. All the children are doing well.

ZYMOTIC DISEASE AT GOOLE.—In consequence of the extensive prevalence in Goole of measles and scarlet fever, the School Board have decided to close their schools for a fortnight.

THE Royal Albert Hospital at Devonport being greatly in need of support, arrangements are being made for a grand amateur theatrical performance to be given in Devonport Theatre on Easter Tuesday.

HOSPITAL SATURDAY FUND.—At a meeting of the delegates of this fund on the 5th inst. it was resolved that the ladies' street collection for the present year take place on June 11th, instead of on June 25th, as previously arranged.

ASSOCIATION OF PUBLIC SANITARY INSPECTORS.—At the annual meeting of the members of this Association on the 5th inst., Mr. J. A. Davenport read a paper on "Rural Sanitation." A discussion, in which several members took part, followed.

WARNEFORD HOSPITAL, LEAMINGTON.—The fifty-fourth annual meeting of the governors of this institution was held on the 2nd inst. During the past year there have been 1135 in-patients and 5614 out-patients treated. The financial report was fairly satisfactory.

Digitized by Google

BEQUESTS.—The late Captain Hamlet Geary, of Dublin, has bequeathed £500 to Jervis-street Hospital, £500 to Mercer's Hospital, £500 to the Meath Hospital, £400 to the Deaf and Dumb Institution, Claremont, and £200 to the Hospital for Incurables.—Mrs. Elizabeth Hughes has left £997 2s. 5d. to the Convalescent Home, Stillorgan.

ABERDEEN SICK CHILDREN'S HOSPITAL. — The annual meeting of the subscribers to this institution was held on the 2nd inst. when it was reported that the number of in-patients treated during 1886 was 355 as against 180 in the previous year, and of out-patients 988. The income amounted to £935, and the expenditure to £1113. A considerable sum has also yet to be raised to meet the expense attending the recent extension of the hospital building.

NATIONAL HEALTH SOCIETY.—On March 1st, at the Paddington Baths, Queen's-road, Bayswater, the Society's certificates were presented by Lady Randolph Churchill to the successful candidates in connexion with the popular Health and Ambulance Lectures recently delivered under the auspices of the Society by Dr. A. T. Schofield. The chair was taken by Dr. Langdon Down, who remarked that the results of the examination reflected the greatest credit upon Dr. Schofield, the lecturer, as well as upon the candidates themselves.

THE LIBRARIAN OF ST. THOMAS'S HOSPITAL.—Many of our readers will learn with regret that Mr. E. H. Denison, who has occupied the position of librarian to St. Thomas's Hospital for the last twenty-five years, has resigned his post. Several of his numerous friends have expressed a wish to give him a testimonial as an indication of the esteem in which he is held, and the first appeal has been most successful. Subscriptions not exceeding a guinea may be sent to any of the treasurers, Messrs. W. Anderson, G. H. Makins, and J. E. Nichol.

EXAMINATION OF CANDIDATES FOR HER MAJESTY'S ARMY, INDIAN, AND NAVAL MEDICAL SERVICES.

NATURAL SCIENCES.

Tuesday, February 15th, 1887.

Zoology.—1. What are the more important modifications presented by the respiratory organs in the adult amphibia? Give one or more examples of each. 2. In what group of the cephelopoda is the ink sac absent? Mention some of the characters which are here specially associated with the absence of an ink sac. 3. Refer to its proper class and order an animal with the following characters, and give one or more examples:—Animal radially symmetrical, with multicellular composition; œsophagus differentiated from the general body cavity, but freely opening into it, and united to the walls of the cavity by radiating mesenteric folds.

Botany.—4. What is the most important difference, as regards anatomical structure, between a moss and a fern? 5. Select any flowering plant you please, and give an accurate description of its pistil. 6. Refer to its natural order a plant with the following characters, and give one or more examples:—Leaves alternate, without stipules. Calyx formed of two sepals which are caducous. Corolla with four petals. Stamens numerous, inserted on the receptacle. Fruit, a single-celled capsule with parietal placentæ. Seeds numerous, with oily albumen.

Physics.—7. An electric current is made to pass through a copper wire above and parallel to the length of a horizontally suspended magnetic needle. What is the effect of the current on the needle? 8. What temperatures on the Centigrade scale correspond to 32°, 140°, and 210° Fah.? 9. What is meant by a river delta? Mention the principal river deltas of the world.

MEDICINE.

Tuesday, February 15th, 1887.

1. A case [given] for analysis and commentary. 2. Name the round worms that have been found in man and their habitat in the human body Explain the mode of development of those you name, and how they find access to the parts of the body in which they are found. 3. Describe the symptoms, course, and differential diagnosis of enteric fever. 4. How would you treat a case of fæcal accumulation in a child, and how is the accumulation to be distinguished from tubercular mesenteric glands? 5. Name the officinal drugs used as emetics. Explain their actions, their uses, and the peculiarities in the action of each.

SURGERY.

Monday, February, 14th, 1887.

1. Describe the process of union of bone in a simple and also in a compound fracture, the conditions under which union may be retarded, and the treatment to be adopted under the latter circumstances. 2. What are the various pathological changes observed in cases of enlarged thyroid gland? Describe the treatment to be pursued in each condition. 3. What symptoms would indicate the existence of abscess of the antrum? What are its chief causes, and what treatment is best for its relief? 4. What are the distinctive characters of a hard and of a soft chancre? How should either be treated locally and constitutionally? What are the sequelæ which usually follow infection? 5. Describe the conditions known as carbuncle. Under what constitutional state does it most frequently occur, and what should be the treatment? 6. A patient is the subject of empyema, the result of acute pleurisy, and immediate relief is requisite. Describe the means by which this may be afforded, and the changes which must occur to ensure the subsequent obliteration of the cavity. Should this obliteration not be effected naturally, what measures should be adopted to produce it?

CHEMISTRY.

Tuesday, February 15th, 1887.

1. What are the more important properties of hydrogen? How may hydrogen be prepared? 2. Write down as an equation the decompositions and new combinations which occur in the process of obtaining ammonia gas by heating ammonia hydrochlorate with quicklime. 3. What are the chief sources of the presence of carbonic acid in the atmosphere?

ANATOMY AND PHYSIOLOGY.

Monday, February 14th, 1887.

1. Describe the astragalus: give an account of its articulations, connexions, and parts of importance which are in proximity to it. 2. Describe the origin, course, distribution, and anatomical relations of the genito-crural nerve. 3. Describe the diaphragm, giving an account of its structure, origin, and insertion, the parts of importance which pass through or are related to it, and the functions which it performs. 4. Describe the thoracic duct, giving an account of its origin, anatomical relations, and structure; also describe the composition, properties, and purposes in the animal economy of its contents. 5. Describe the origin, course, and distribution of the facial artery, giving also a brief account of the dissection by which you would expose the vessel and its branches.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE MOXON MEMORIAL FUND.

President: Sir William Jenner, Bart., K.C.B., M.D., F.R.S.

THE following contributions have been received since those acknowledged on March 5th. All subscriptions should be forwarded to the honorary treasurer, R. Clement Lucas, B.S., F.R.C.S., 18, Finsbury-square, E.C., by whom they will be acknowledged, and cheques should be crossed "City Bank."

Errata.—The name of T. A. Spalding was the name on the cheque for £2 2s. sent by Dr. L. E. Shaw, which was thus twice acknowledged last week. "J. F. Table, Esq." should be J. F. *Tabb*, Esq. The names of Dr. Langdon Down and W. A. Garrard, Esq., each for £1 1s., were omitted last week.

Mr. G. W. Hambleton.—There can be no objection to publishing the cases with the treatment adopted.

Dr. C. J. Parsons.—An advertisement, no doubt.

"THE MEDICAL PROFESSION AND LIFE ASSURANCE OFFICES."

To the Editors of THE LANCET.

SIRS,—I was one of those favoured, as was Dr. Thursfield, by a communication from the National Life Assurance Society, and, like him, I indignantly declined to enter into an engagement which, in my opinion, would be most injurious to the interests of the profession, as well as to the offices themselves.—I am, Sirs, yours faithfully,

Cardiff, March 9th, 1887. C. T. VACHELL, M.D. Lond.

STEAMSHIP ARRANGEMENTS FOR THE AMERICAN CONGRESS.

Mr. Boyd B. Joll states that, so far as he can ascertain, the reason why the principal American steamship companies, such as the "White Star" and "Cunard" lines, have not offered to make any reduction in the tariff for members of the medical profession who purpose attending the Congress at Washington in September next is that so few have hitherto signified their intention of being present at the meeting. If those who wish to proceed by one of the Royal Mail lines will communicate with Mr. Joll, stating by which company's steamers they wish to travel, he will wait upon certain of the directors of these lines with whom he is personally acquainted, and see what reduction they can be induced to make. Of course, the greater the number proceeding by one line of steamers, the better chance of getting favourable terms with the directors.

Juvenile will do well to follow the custom which has hitherto been observed in the locality.

Mr. H. C. Fox.—The address is No. 2, Delamere-crescent, Bayswater, W.

Mr. Patwardhana (Poona).—We cannot exchange.

PROVIDENT DISPENSARIES: THE WANDSWORTH MEDICAL AID SOCIETY.

To the Editors of THE LANCET.

SIRS,—If Mr. Cox, by the aid of Johnson's Dictionary, described to Mrs. Bouncer the correct definition of a grumbler as being a "person who finds fault without cause," your correspondent, in his letter of to-day, in rejoinder to Mr. Dickinson's of Dec. 7th on the above subject, has very properly adopted that designation. As regards provident dispensaries in general and the Wandsworth Provident Dispensary in particular, his opinion may be allowed to pass, but as regards the Wandsworth Medical Aid Society, his remarks demand some comment, for he is wrong in his facts, in his premisses, and in his conclusions concerning that institution. The latter is not a charitable society; based on the principle of mutual assurance, it is independent of eleemosynary or other extraneous aid, and is entirely self-supporting. By payments that are very small from each individual, but which collectively furnish a not unreasonable fee to the medical attendants, it ensures to the working classes efficient medical attention, without which (inasmuch as about 72 per cent. of all pauperism results from sickness) a large number of them would become paupers. The medical attendants do not attend cases of sickness at 4*s.* per annum, but the number of sick that occur in a given number of healthy members for the sum total subscribed by the latter. And as the sickness averages 5 per cent., "A Grumbler" will find that the sum paid for each case attended per annum constitutes a by no means ignominious fee. The medical attendants therefore do not put on "the cloak of charity" for the base motives imputed to them by "A Grumbler," nor do they give their services in the manner described for the purpose of "starving a new man or of giving vent to their professional jealousy." Jealousy of whom? Of the new man? It would rather seem to be the jealousy or envy of the new man that has brought forth "A Grumbler.' Is it their fault that the newcomer is at his wits' end "how to start a practice" without the aid of that class of persons styled by him the "ragged lot," whose shilling or two he nevertheless does not affect to despise? The idea that the old-established practitioner ought "to stand and deliver," on demand of any newcomer, one portion of his practice as a means of getting himself "eased" of the remainder, is a bit of new morality, so simple in conception that it is scarcely likely to be entertained in any mind but that of "A Grumbler." His accusations are simply without foundation; although ostensibly general, they are obviously intended to have a local application.—I have the honour to be, Sirs, your obedient servant, and not ashamed to subscribe myself,

G. H. NICHOLAS, M.D.
(One of the Promoters of the Wandsworth
Church-row, S.W., Feb. 12th, 1887. Medical Aid Society.)

A Medical Poet.—We do not think the suggestion could be usefully carried out. The troughs would not be likely to be employed by the careless class of persons referred to.

Mr. Leonard Keyser.—The reply to both questions must be in the affirmative.

NIGHTMARE.

To the Editors of THE LANCET.

SIRS,—I think if your correspondent, "M.D.," will take the following mixture the nightmare from which he suffers will give place to more peaceful sleep. When he has taken the mixture a fortnight it would be interesting to know the result. Personal experience has taught that great relief will follow:—℞. Pulv. rhei, gr. ii.; liq. ammon., ♏x.; sod. bicarb., gr. xii.; ol. menth. pip., ♏i.; aquæ ʒi.; ter die. I am supposing "M.D." to have eliminated indigestible articles from his usual diet.

I am, Sirs, yours truly.
March, 1887. R. W. W.

To the Editors of THE LANCET.

SIRS,—In answer to "M.D.," I believe that any of the following may cause disturbance of sleep such as he describes:—supper, sexual excess, smoking, tea-drinking, over-reading, the last three especially if indulged in at night. Treatment:—Avoid the above. If possible, take a short holiday, and make a point of having out-door exercise.

I am, Sirs, faithfully yours,
March, 1887. G. H. S.

FURNEAUX JORDAN TESTIMONIAL FUND.

Final List.

Crompton, D. W., Esq.	£3	0	0	Jackson, Vincent, F.R.C.S.	£1	1	0

T. H. Bartleet, Treasurer; Bennett May and Jordan Lloyd, Secs.

Surgeon-Major.—We trust that our correspondent will feel reassured by the statement made by the Director-General, at the dinner of the Medical Society, which he will find reported in our present issue.

Cyclist.—We see no objection to the patient's riding the machine, providing a carefully applied and well-fitting truss is worn, and racing is forbidden.

Dr. Bennett (Leicester).—The criticism had, perhaps, better wait for publication until the whole of the paper has appeared.

PARALDEHYDE.

To the Editors of THE LANCET.

SIRS,—The great advantage possessed by paraldehyde over chloral is that it has no depressing or paralysing effect upon the heart. In all other respects it is almost indentical with chloral. If your correspondent, "Subscriber," will refer to THE LANCET of Jan. 31st, 1885, he will find a short paper written by me on the action of paraldehyde. I there stated that I had found the drug to be an equally sure hypnotic with chloral; that in the rare cases in which it did not produce sleep it never caused excitement; that it left no headache or other unpleasant after-symptom, and that it did not affect the appetite even when given regularly for a considerable time. During the two years that have passed since I wrote the paper alluded to I have regularly prescribed it, and have no reason to change the opinions there stated. It possesses every good quality of chloral and is without its most dangerous—viz., its paralysing action upon the heart. It may be given in doses of from forty to ninety minims with safety, even where the heart is weak and irregular, or, as in the second stage of febrile diseases, where the cardiac muscle has undergone fatty degeneration. In ordinary cases of insomnia forty minims are generally sufficient to induce sleep; and this dose repeated, if necessary, in fifteen minutes I have found more efficacious than a larger single dose. I may say I have discovered no better mode of administration than with a vegetable bitter in simple syrup.

I am, Sirs, yours faithfully,
March, 1887. S. A. K. STRAHAN, M.D.

MEDICAL ADVICE THROUGH NEWSPAPERS.

Mr. T. R. Allinson, L.R.C.P. Edin. & L.R.C.S. Edin., continues to give his advice with much profusion through a newspaper, accompanied with a little commercial advice to his correspondents, to recommend "his paper." Much of Mr. Allinson's advice is good enough. Some of it is very doubtful, as, for example, that to "Jimmy," who is afflicted with diabetes, and told to drink nothing but milk, which will stop his thirst. However, our object is not to discuss "Jimmy's" prospect with diabetes on a milk diet, but the newspaper method of advertising one's professional wisdom and the particulars of "Jimmy's" or "Jessie's" complaint.

JUBILEE SUGGESTIONS:

To the Editors of THE LANCET.

SIRS,—With a view of celebrating our Queen's Jubilee, and of accomplishing the wishes of various medical bodies of gaining higher professional and distinctive titles, will you allow me to suggest the following:—1. That all L.M.K.Q.C.P.I.'s should be allowed to add the *few* remaining letters of the alphabet to their names. 2. That as the examination of the Apothecaries' Hall now includes surgery, those holding that diploma should be considered eligible for the post of consulting surgeons to hospitals, and be allowed to use the title of professor. 3. That all members of the Colleges of Surgeons, and licentiates of the Colleges of Physicians in Great Britain, should have the right of using the title "M.D. Jubilee" after their names. 4. That all who hold the university title of M.D. at present should be made baronets, or at least life peers. 5. That all unqualified assistants of more than fifty years' standing, and who can prove that they have never entered the walls of a hospital except as patients, should be admitted at once upon the Medical Register and rank as Fellows of the College of Surgeons. If these suggestions be carried out in the spirit in which they are offered, the present dissensions would soon cease, and a time come when the highest and lowest medical titles will be as one, and the rivalry of the licensing bodies put a stop to altogether.

I am, Sirs, yours faithfully,
A. G. BATEMAN.
Constitutional Club, Northumberland-avenue, March, 1887.

A NEW GULLY FOR YARDS.

MR. SHAW, of Willington-on-Tyne, has sent us a drawing of a gully to be used in houses and yards. It is a great advance upon the old bell-trap, for the reason that it has in combination with it a syphon trap, which will effectually prevent the drain from becoming untrapped so long as water is supplied to it.

Dr. J. B. Sim (Nottingham).—Yes, shortly.

DENTAL STATISTICS.

ACCORDING to the *Dental Review* there is in America one dentist for every 4000 inhabitants; in France, one for every 37,000; in Germany, one in 88,000; and in Austro-Hungary, one in 200,000. In England there is one for every 7000.

G. A. M.—We doubt if our correspondent has any legal claim.

THE LONDON HOSPITAL STUDENTS' DINNER: A WAIL FROM THE WILDERNESS.

To the Editors of THE LANCET.

SIRS,—The other evening I attended the first annual dinner of the London Hospital students, where it was suggested that I should respond for the "The Visitors." Up till then I had fondly imagined myself a student of the hospital, having paid a composition fee, attended lectures, dissected several parts, and dressed in the hospital. My connexion with the school is briefly this: After taking an Edinburgh diploma I spent five or six years abroad and otherwise, and then came to town to read for the higher qualifications. Looking round for a hospital, I deliberately chose the "London" for its brilliant staff and fine clinique, and entered there, intending to go through such a course as would enable me in time to apply for a house-surgeoncy. Events prevented me from carrying out that intention, but I still considered myself a student of the hospital until there came the sudden awakening. Now, one is tempted to ask, with Truthful James, "Are things what they seem, or is visions about?" If the receipt before me from the warden for forty-five guineas, the first instalment of a composition fee, does not constitute one a student of the London Hospital, how is that enviable position to be attained? Evidently not by purchase, wherefore I thank heaven with mild philosophy that the second instalment has not been paid. Some months back I met a medical man, an old student of the London Hospital, and in answer to his inquiry explained my connexion with the place; whereupon he said: "Oh, you are one of those qualified men who go there for the appointments!" This remark showed a want of breeding or want of tact that inclined one to ignore and forget it as soon as possible; and the incident had passed out of my mind until recalled by the dinner. In ancient times death was often the penalty for those who strayed into sacred enclosures, and by comparison it is terrible to think what may be the sentence on composition students who have trespassed into these charmed circles. For my own part, I should be sorry to thrust myself into any society of men, however distinguished, were it made plain that my presence was not wanted, and I am willing formally to resign all claim to be called a student of the London Hospital. Not that this declaration is likely to fill either of the contending camps with great joy or despondency; but one cannot hear too many sides of a question. Besides, now that I have tasted the delights of suburban practice and am freed from scholastic thraldom many things appear in a different light. House-surgeoncies have lost the halo of glory that formerly surrounded them, for a small practice in the wilds has permitted perineal section, removal of deep-seated glands, osteotomy, and other operations denied to resident officers. Bearing these things in mind, the feeling gathers weight that a man of fair education, energy, and self-reliance, with the help of a few books of reference and thorough antiseptic methods, may live a happy and useful life (and even occasionally operate) independently of consultants, high degrees, hospital appointments, or connexion with particular schools. One comfort is that the fields of literature, science, and art are just as open to a humble licentiate as to one who writes a string of titles after his name.

In conclusion, the students of the London Hospital have my hearty wishes for success in efforts which seem to have a solid groundwork of justice, although this goodwill must sound rather strangely coming from one who has been put "outside the walls."

I am, Sirs, your obedient servant,

DAVID WALSH, L.R.C.S. and L.R.C.P. Ed.

Gulstonian Lectures
ON THE
NATURE OF FEVER.

Delivered at the Royal College of Physicians,

BY D. MACALISTER, M.A., M.D., F.R.C.P.,
PHYSICIAN TO ADDENBROOKE'S HOSPITAL, LECTURER IN MEDICINE AT THE UNIVERSITY OF CAMBRIDGE.

LECTURE II.

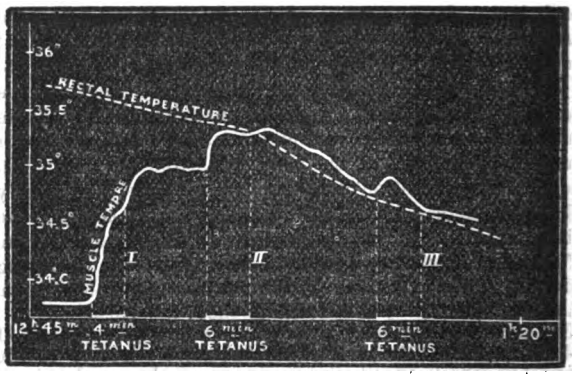
MR. PRESIDENT AND GENTLEMEN,—Let me recall to your memory the point we have now reached in our discussion of the nature of fever. Perhaps I can best do so by reciting the conclusions arrived at in 1875 by Dr. Burdon Sanderson in the important memoir I have already referred to. These conclusions will not only serve to indicate the first stage of our argument, they will be useful as a starting-point for the considerations that are yet to come. "Two possibilities [as to the origin of fever] are open to us. One is that fever originates in disorder of the nervous centres, that by means of the influence of the nervous system on the systemic functions the liberation of heat at the surface of the body is controlled or restrained, so that 'by retention' the temperature rises, and finally that the increased temperature so produced acts on the living substance of the body so as to disorder its nutrition. The other alternative is that fever originates in the living tissues, that it is from first to last a disorder of protoplasm, and that all the systemic disturbances are secondary..... The facts and considerations we have had before us are, I think, sufficient to justify the definitive rejection of the first hypothesis in all its forms; for, on the one hand, we have seen that no disorder of the systemic functions or of the nervous centres which preside over them is capable of inducing a state which can be identified with febrile pyrexia; and on the other, that it is possible for such a state to originate and persist in the organism after the influence of the central nervous system has been withdrawn from the tissues by the severance of the spinal cord. We are therefore at liberty to adopt the tissue origin of fever as the basis on which we hope *eventually* to construct an explanation of the process. But if we attempt to do so *now*, we shall at once find ourselves in face of an unsolved physiological problem—that of the normal relation between temperature and thermogenesis,—for the elucidation of which it is necessary to investigate much more completely than has yet been found possible the influence of temperature variations on those chemical processes in living tissue with which thermogenesis is necessarily associated."

As these sentences are somewhat condensed in expression a word or two of comment may prevent misunderstanding. In the first place, the "disorder of the nervous centres," which is without hesitation condemned as inadequate to explain the genesis of fever, means primarily disorder of that part of the nervous system which governs the circulation and the respiration—"the systemic functions," as they are called. This is clear from the whole course of the previous argument. The apparently sweeping rejection of the hypothesis of nervous disorder "in all its forms" is really levelled at the hypothesis of merely vaso-motor disorder, which is associated with the names of Traube and Marey; hence if we are led hereafter to consider a theory involving another kind of nervous disorder we shall not necessarily come under Dr. Sanderson's condemnation. In the next place, since 1875 something has been done to supply the missing physiological data for the establishment of the tissue origin of fever, and something more has been done on other lines which help us to get round the outstanding problems. Moreover, as I explained in my last lecture, we have had an authoritative re-examination and re-determination of some of the points in regard to febrile thermogenesis which Dr. Sanderson was inclined to regard as doubtful or not proven in the earlier experiments of Leyden and Senator, with the result of showing that though the methods were imperfect quantitatively the deductions from them were qualitatively correct. Thirdly, we have had from various quarters—England, France, Germany, and America—valuable researches on the relation of the body temperature and the body heat to certain parts of the central nervous system, researches which were not before Dr. Sanderson when he wrote, and which open up new lines of thought regarding the mechanism of fever. Lastly, some light has been thrown on the relation of the nervous system in general to the "chemical processes in living tissue with which thermogenesis is necessarily connected." All these gains to knowledge enable us to advance further towards a true theory of fever than was thought twelve years ago to be possible, though the "unsolved physiological problem of the normal relation of temperature to thermogenesis" is not yet fully solved. I shall endeavour to show the bearing of these later contributions, and so lead step by step to a theory of the "tissue origin of fever," such as Dr. Sanderson forecasts.

We start with this: that fever of necessity implies—(1) A disorder of the thermotaxic mechanism; (2) an excessive production of heat associated with excessive chemical changes in the tissues, the excessive production being more or less than that of a normal patient on full diet (perhaps oftener less than more), but more than that of a normal patient on fever diet; and (3) that the body temperature, depending on the state of the balance between production and discharge, fluctuates as one or the other is in the ascendant, and is not *per se* a true *measure* of either, or of the consumption of tissue which may be going on. An essential factor of fever being thus excessive production of heat in proportion to the food consumed, a natural question to ask is, What tissue or tissues in particular are concerned in the excessive thermogenesis? If there is increased combustion, what is the fuel, and where the furnace? To answer this question we shall first have to ask another—the licence is permitted to a Scotsman: What are the sources of heat production in health?

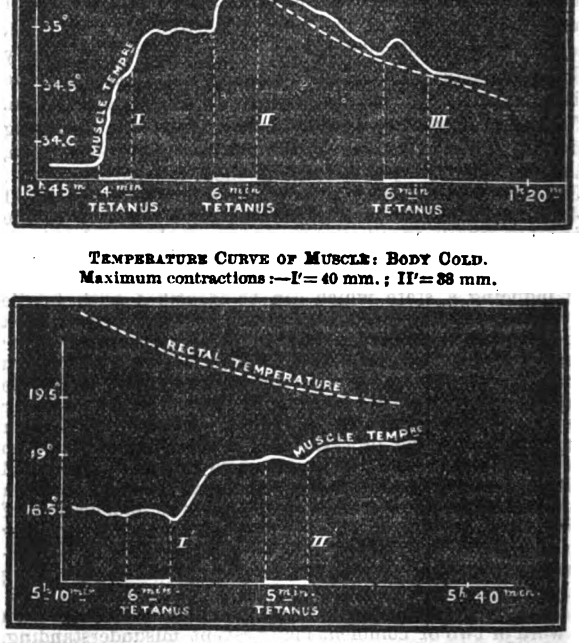
The older notion connected with the great name of Liebig, that the hydrocarbons of the food are the "fuel" of the body, being consumed chiefly in the lungs during respiration, while the nitrogenous constituents are mainly plastic or tissue forming, has been so effectually disproved that I need not pause to discuss it. It still reappears in popular books, and we occasionally see in the medical journals—at least on the outside pages—published analyses of particular foods which are duly parted into "heat-givers" and "flesh-formers." Now, however, to use Professor Foster's words, which I need not paraphrase, because I cannot improve on them, "we may at once affirm that the heat of the body is generated by the oxidation not of any particular substances, but of the tissues at large. Wherever metabolism of protoplasm is going on heat is being set free. ..... In growth and in repair, in the deposition of new material, in the transformation of lifeless pabulum into living tissue, in the constructive metabolism of the body, heat may be undoubtedly to a certain extent absorbed and rendered latent; the energy of the construction may be in part, at least, supplied by the heat present. But all this, and more than this—namely, the heat present in a potential form in the substances themselves so built up into the tissue—is lost to the tissue during its destructive metabolism; so that the whole metabolism, the whole cycle of changes from the lifeless pabulum, through the living tissue, back to the lifeless products of vital action, is eminently a source of heat."[1] But of the "tissues at large," whose oxidation is in general the immediate source of the body heat, the muscles for various sufficient reasons must be regarded as the chief contributors. In the first place, the muscles form something like one-half the whole mass of the body. When we reflect that of the other half a large portion is made up of the bony tissues, whose oxidation cannot be active, we see that the muscles must play a very large part in thermogenesis. In the next place, even when the muscles are at rest the blood which leaves them by the veins contains more carbonic acid than the blood even of the right ventricle. The mean rate of oxidation in the muscles is higher than that of the average of all the tissues, including the muscles themselves. And, lastly, muscular exercise, in which the metabolism, as evidenced by the increased excretion of carbonic acid, is markedly increased, is accompanied by a large concomitant increase of heat production. Fick makes a calculation, based on the actual observation that during severe muscular work the quantity of exhaled carbonic acid may be five times the

[1] Physiology, p. 461.



Digitized by Google

normal, showing that of the total energy derived from the food one-sixth goes to the work and five-sixths to the extra production of heat that accompanies it.[2] I need not enumerate all the other reasons for regarding the muscles as "the thermogenic tissues *par excellence*;" those I have given are perhaps enough. Next to the muscles come the various secreting glands, and the alimentary canal in digestion. But when we remember that in fever the functional activity of these latter is to a great extent in abeyance, we shall probably not credit them with any large share in the genesis at least of febrile heat. As regards the muscles, however, they are estimated to contribute four-fifths of the body heat in health; in fever their proportion must be higher still. Briefly, then, we may say that the muscles are the chief furnaces of the body both in health and in fever. Let us consider more minutely this thermogenic function of the muscles, and the nature of its connexion with the more familiar motor function. The investigation will be worth our pains, even if it only leads us to hesitate in regarding the heat produced in muscles as a mere excretion, a waste-product like urea or carbonic acid.



It has long been known that each contraction of a muscle is accompanied by the production of a certain modicum of heat. The earlier experimenters put forward the idea that as in a steam engine the energy supplied by the hot vapour from the boiler is given out partly as work and partly as heat, so in a muscular contraction the energy set free by a given stimulus appears partly as mechanical effect and partly as inevitably waste or degraded energy in the form of heat. It was inferred on the principles of the dynamical theory that if we should add the work done by the muscle to the mechanical equivalent of the heat wasted we should have a constant sum. The more work done in contracting the less waste energy in the form of heat, and *vice versâ*. But when exact quantitative experiments were made, such as those by Fick, Heidenhain, and many others, it was found that no such constant relation could be demonstrated. The proportion of heat to work, and the sum of these two elements, depended not on the intensity of the originating stimulus, but on various external conditions, such as the load the muscle had to bear, the extent to which it was stretched, and so on. In fact, the productive efficiency of the muscle considered as a machine was far more complex in character than that of a steam-engine. Many have been the attempts to determine more precisely the quantitative laws of this efficiency, but they all seem to proceed on the assumption that some necessary thermo-dynamic connexion exists between the function of work-producing and the function of heat-producing, between the motor and the thermogenic activities of the muscle; and it has been sought to define the nature of the assumed connexion in terms of a small number of variables. For some years I have asked myself the question: Must in *all* circumstances heat be produced when a muscle contracts? If heat is produced without contraction, may not contraction take place without heat? The older methods of investigation offered practical difficulties when I came to seek an answer to this question. The muscle experimented on was generally that of a frog or cold-blooded animal; it was removed from the body, and therefore from the influence of the circulation—in fact, it was a dying muscle rather than a living one. Moreover, the quantities of heat and the temperatures which were measured were on the whole extremely small, being reckoned in hundredths or thousandths of a degree. The limits of error in such measurements are naturally wide, and the measurements require the most sensitive thermo-electric instruments to make them apparent.

Working under the inspiring guidance of Professor Ludwig in 1881, and still possessed with the idea of the thermo-dynamic interdependence of muscle work and muscle heat, I thought it worth while to see whether the heat production of a frog's muscle still connected with the body and permeated by the circulating blood might not be great enough to admit of thermometric measurement instead of thermo-electric. Some previous experiments of Dr. Meade Smith in the same direction had made this probable. I procured very sensitive thermometers with fine-drawn bulbs, and openly graduated in tenths of a degree Centigrade. I found that one of these could be introduced beneath the skin of a pithed frog into the natural intermuscular cleft between the muscles of the thigh, so as to be surrounded on all sides by living flesh, but without injuring anything. When the sciatic nerve was suitably stimulated, the muscle contracted tetanically and the temperature rose. The rise was easily legible, amounting to four or five tenths of a degree. When several successive tetanic contractions were induced, the rise of temperature grew less and less, and at last could not be read at all, though the contraction was quite marked. In a word, the muscle was fatigued as a heat-producer before it was fatigued as a work-producer. These experiments were performed in winter on frogs collected in autumn, and I observed that as spring came on the heat production in the muscles under uniform conditions gradually grew less and less, though the tetanic curves given by them on stimulation were excellent. I attributed this to the gradual exhaustion of the frogs by their long winter fast. But the point of interest was that the heat-producing power was sooner exhausted than the work-producing power of the muscles. Fatigue from repeated stimulation, exhaustion from long abstinence, each appeared to differentiate the thermogenic function from the motor function. I next proceeded to inquire whether in warm-blooded animals it might not also be possible to separate the two functions, to show that, though generally called into play together, they were capable of being performed independently. Using dogs, guinea-pigs, and rabbits, narcotised with chloral in all cases, I made a number of experiments on the fatigue of the thermogenic function, and almost accidentally discovered another method of practically abolishing it while the motor function remained nearly, if not quite, intact. By controlling the temperature of the whole animal, including that of the muscle under observation, I found that I could vary within wide limits the relation between the work and the heat produced. It is not necessary to give the experimental details at length. Suffice it to say that by enclosing the profoundly narcotised animal in a box with double walls, through which water of any desired temperature could be made to circulate, I was able to raise or lower its body temperature at will. Arti-

TEMPERATURE CURVE OF MUSCLE: BODY WARM.
Maximum contractions:—I = 47 mm.; II = 41 mm.; III = 38 mm.

TEMPERATURE CURVE OF MUSCLE: BODY COLD.
Maximum contractions:—I' = 40 mm.; II' = 38 mm.

I illustrates the post-tetanic rise of temperature, owing to the flushing of the muscle with warmer blood.
II illustrates the effect of fatigue in reducing the thermogenesis; the tetanic rise is diminished; the post-tetanic rise is almost absent, the blood being scarcely warmer than the muscle.
III illustrates the post-tetanic fall when the blood is cooler than the muscle.

[2] This and other facts recited in this lecture I owe to the kindness of Dr. A. Sheridan Lea.

ficial respiration was maintained for hours together. The temperature of the blood in the aorta, in the rectum, and in the mass of the calf muscles could be ascertained from minute to minute by means of fine thermometers; the mechanical work done by the muscles of the calf could be estimated by the motion of a cord fastened to the Achilles tendon; and, lastly, the sciatic nerve, severed from the spine, could be electrically stimulated. The arrangements were elaborate, but after much experience and many failures I succeeded in getting some fairly satisfactory results.

The experiments were made in triads. First, say, at ordinary temperature, the reading of the thermometers showing that all was steady, a tetanic contraction would be set up, and the muscle temperature read at minute intervals, before, during, and after the stimulation. The whole arrangement would then be cooled down, say, to 16° or 18° C. (say 61° or 64° F.) When things were once more steady, a tetanus of the calf muscles was again induced, the muscle temperature being read at short intervals as before. Once more the temperature of the animal as a whole was raised back to the original point, and the experiment repeated. By varying the stimulus the extent of the mechanical contraction was kept as nearly as possible the same in all three experiments. Usually such a triad of experiments lasted the whole day, as the processes of cooling down and warming up occupied several hours each. In some cases I varied the procedure by first cooling the animal, then warming it, and lastly cooling it again; but it was difficult to get very satisfactory results by this method, which was very exhausting to the observer, as well as to the animal. I need hardly say that the latter was never suffered to regain consciousness. The general character of the thermal results may be gathered from the rough diagrams I present. (See *ante*.) Take first an experiment at about 35° C. As soon as the muscle contracts, its temperature rises, and continues to rise for some time after the contraction ceases. The animal is then cooled to, say, 19° C. On stimulation the muscle contracts forcibly, but the rise of temperature is trifling or absent. On rewarming the animal to something like its first temperature, we once more restore the rise of temperature on contraction. There are several other points of interest exhibited in these curves, but I do not propose to dwell on them at present. I will only say that the post-tetanic rise of temperature, when it exists, is due to the post-tetanic flushing of the muscles with blood that is warmer than the muscle. When the blood is cooler than the muscle, as sometimes happened, we have a post-tetanic fall of temperature. Some plethysmographic experiments convinced me that this explanation, based on what in Germany is sometimes called "das Gaskell'sche Phänomen," is applicable to all the peculiarities of the curves. A study of these peculiarities, moreover, shows that the absence of thermal phenomena was not due to any perceptible impairment of the vaso-motor mechanism of the muscle at the lower temperatures. The lesson taught by these experiments appears to be—first, that the motor function may persist while the thermogenic function is in abeyance; and secondly, that *cold* is capable of abolishing or notably depressing the latter function, while the former is still but little or not at all affected. The therapeutic bearing of the second lesson is not unimportant.

Since 1881, two investigators also working in Professor Ludwig's laboratory have carried on the research in other directions. Dr. Meade Smith and Dr. Lukjanow,[3] in a memoir that has lately been published, display in minute detail the laws which govern the fatigue of the thermogenic function of a living muscle—(1) with the blood-supply shut off for a time, and (2) with the blood in full circulation. They also investigate the law of recovery of this function when it is completely exhausted, so far as it is effected by simple rest with or without blood-supply. The outcome of these experiments may thus be expressed: The effect of stimulating a muscle through its nerve is to start in it two processes—one, as it were, explosive, and manifested by change of form and the performance of mechanical work; the other more continuous, and manifested by the increased development of heat. Each process has its own laws as regards (1) the influence of external conditions—such as intensity of stimulus, load, extension, and so on; (2) the influence of fatigue from repeated stimulation; (3) the influence of general exhaustion from inanition or other debilitating causes; (4) the influence of the general temperature of the protoplasm of the muscle; and (5) the influence of rest and of the circulating blood in restoring lost power. This independence, I think, justifies us in assuming that the two processes are largely independent and coördinate. The heat developed in the second or thermogenic process is not simply a thermo-dynamic waste-product, an excretion of no greater dignity than urea or carbonic acid. On mechanical principles, the dislocation of the parts of the muscle on contraction, and again on relaxation, must give rise to a small quantity of heat, which one might call thermo-dynamic waste. It is the outcome of the degradation of the kinetic energy of contraction, such as occurs when any moving mass overcomes friction or is reduced to rest. But the amount of this waste heat is calculable, and it comes out as perfectly trifling in comparison with what I may call the thermogenic heat. In some of the experiments of Lukjanow it was much less than 1 per cent. of the heat liberated simultaneously with contraction.

The processes which issue in motion on the one hand and in thermogenesis on the other are of course associated with chemical movements in the muscle, with metabolisms whose terminal steps are the accretion of oxygen and the excretion of carbonic acid and water. The considerations I have adduced, and especially those relating to the power of recovery in a fatigued muscle under the influence respectively of rest and of the blood-supply, point to the conclusion that the two metabolisms are in some way different. In other words, that the "contractile stuff" in the muscle is not the same as the "thermogenic stuff." Both of them are stored in the muscle; so far as function is concerned they *are* the muscle. The store of each can be exhausted by repeated stimulation, but in some cases the thermogenic store sooner than the other. Both can be upbuilt again by the circulating blood, but in some cases the contractile store sooner than the thermogenic. Both the metabolisms are affected by cold, but the thermogenic much sooner and much more intensely than the contractile. We know little of the exact nature of the chemical changes involved in either form of metabolism. Oxygen is taken up in each, and carbonic acid is discharged, but the processes passed through between these terminal stages are much more complex than simple oxidations. The evidence rather goes to show that it is the living substance as a whole, contractile stuff and thermogenic stuff, which is continually being decomposed and as continually being recomposed by the blood. The net balance shows only gain of carbonic acid and loss of oxygen, but the nitrogenous parts also of the working substance have in the process undergone partial destruction and equivalent reconstruction. This is in health; but if the reconstructive part of the process is inadequate or absent, the balance of accounts will give evidence of a nitrogenous residuum which is morbid. The muscle substance will appear to be itself consumed; it will no longer be what I may call merely the circulating medium of consumption. I say it will *appear* to be consumed; this only means that the *net* result is loss of nitrogenous substance. The cast-out nitrogenised molecules of the muscle are not really excretionary in the sense that carbonic acid is excretionary. They have merely failed of that immediate upbuilding into muscle substance again which is characteristic of the healthy metabolism. This incessant upbuilding of the muscle substance, which is a necessary consequence of the fact that no increase of urea or other nitrogenous matter is produced in the ordinary processes of muscular metabolism, must require the expenditure of a certain amount of energy. If in any measure the upbuilding is checked or abolished, so much energy is of course unexpended. It was on some such asset of energy as this that, as I presume, Dr. Ord fixed his attention in the suggestive paper[4] of which I spoke in the last lecture. He asks: "Is the increment of heat of the body in fever due not only to combustion or other disintegrative processes thereto allied, but also to the persistence in the form of heat of energy which should have taken another form?" I believe that Dr. Ord's claim on this asset must be allowed, at least so far as it refers to that part of the muscle substance which in fever fails to be reconstructed. But I fear the asset is a very small one at the best, and quite inadequate to provide a large addition to the heat-production of fever. Moreover, it would be measured in a rough way by the loss

[3] Du Bois Reymond's Archiv, 1886.

[4] Brit. Med. Journal, vol. ii., 1885.

Digitized by Google

of nitrogenous substance in the muscle—in other words, by that very combustion of the tissues which Dr. Ord himself regards as already inadequate to account for febrile heat. When he goes further and extends his claim over the whole field of the tissues, in which normal constructive metabolism implies the locking up of energy, and when he infers from the absence of tissue formation in fever that the locked-up energy must therefore all "run wild" and take the form of heat, I fail to follow his argument. Granted that in fever tissue formation is to some extent in abeyance, are the materials and the energy for tissue formation still being supplied in normal quantity? We cannot credit ourselves with the possession of unused energy till we are sure that the full tale of energy is being supplied and not used. In other words, until account is taken of the low diet of fever we cannot say with Dr. Ord that the energy which in health is utilised in tissue-forming is in fever all available for heat-producing.

To return now to the thermogenic metabolism of the muscles. I have already implied, but may usefully state here in so many words, that in ordinary conditions it is continually going on as a quiescent but unceasing process. Contraction is accompanied by an increase of it, but contraction is not necessary to it. So long as the blood-supply and the nerve-supply are intact, the muscle, whether visibly moving or visibly resting, works unceasingly at its business of heat production. I say so long as the blood-supply and the nerve-supply are intact: we have already touched on some of the ways in which the blood-supply is related to the thermogenic function; we have now to consider the relation of the nerve-supply.

When we stimulate the nerve going to a muscle, two obvious processes are set up in the muscle substance. The one issues in temporary contraction; the other temporarily increases the production of heat. When a muscle is poisoned by curare, both these effects of the stimulation are done away. As we know, curare abolishes the function of the peripheral nerve endings, and thus blocks the way for the transmission of impulses from the nerve trunk to the muscle. The thermal behaviour of an animal in whom the thermogenic tissues are thus cut off from the influence of the nervous system is very remarkable. The vaso-motor mechanism is intact, but the animal can no longer maintain its temperature. If it is plunged in a cooler medium, its temperature steadily falls; in a warmer medium it steadily rises. It is, in fact, the plaything of the external conditions: it is to all intents a cold-blooded animal. Still more remarkable is the change in the quantity of its oxidative metabolism, as manifested by the consumption of oxygen and the exhalation of carbonic acid. Both of these fall in the cooler medium to a mere fraction of the normal.[5] The circulation remains unaffected; the respiration can be artificially maintained. The cause of the change can only be the interception of the nervous influences that normally reach the muscles. Two inferences are inevitable: (1) that the thermogenic function of the muscles is primarily dependent on their innervation; and (2) that the share of the muscles in the oxidative metabolism, the combustion processes of the body, is so great that when they are excluded a mere fraction of the whole alone remains. This second inference confirms and justifies the attention we have concentrated on the muscles as the chief sources of heat, normal and febrile. The first inference leads us from the muscle to the nerve. But if when no contraction is going on the normal muscle is continually undergoing an active oxidative metabolism, and if this metabolism is dependent on active innervation, we must conclude that through the nerve trunks at all times there is kept up a continuous stream of nervous influence. In other words, that in the resting muscle a constant *thermogenic tonus* is maintained. The old arguments for the existence of a constant motor tonus in muscle now appear to be inadequate, though its impossibility is by no means proved. As regards the vaso-motor muscular system, however, there seems no doubt that such a tonus, such a degree of steady moderate contraction, does exist. There is, if I may so call it, a state of strained equilibrium between the vaso-constricting and the vaso-dilating influences, and the result is that mean condition—ready to be altered either way as one influence or the other preponderates—which we call arterial tone. And in the case of the respiration we have something very similar. In ordinary automatic breathing there is a steady rhythmic balance between the inspiratory and the expiratory impulses sent to the muscles of respiration—rhythmic but yet balanced, as are the impulses that maintain a planet in its elliptic orbit round the sun. Indeed, as I have already hinted in passing, it is possible to explain the automatic mechanism of respiration by regarding the balanced impulses as simply motor and inhibitory of the inspiratory muscles. The periodic equilibrium is capable of perturbation by various reflex and volitional causes; the breathing can be augmented or depressed in various ways; but in the normal self-regulated condition we have what we may call a *nervous tonus* of the respiratory centres. Now, as the vascular tonus is the result of a strained equilibrium between the opposing impulses given to the unstriped muscle of the arterial wall—the opposing impulses sent along the vaso-constrictor and the vaso-motor fibres,—and as the nervous tonus of the respiratory centres is in like manner due to what I have called a rhythmic balance or periodic equilibrium between motor and inhibitory influences, so I am fain to regard the thermogenic tonus of the muscles as the manifestation of a balance between two opposing innervations. But you will perhaps say, Granted that in respiration there is a balance between two tendencies, the nature of these tendencies is obvious—there is inspiration and there is expiration; and in the tonus of the arteries the two opposing tendencies are equally obvious—there is constriction and there is dilatation. What are the two tendencies that are balanced in the thermogenic tonus? The answer is: first, the tendency to the upbuilding and storing of what I have bluntly called the "thermogenic stuff" of the muscle—the *thermogen*, if I may coin the word; and, second, the tendency to disintegrate this by a process involving oxidation. At Cambridge we are accustomed to speak of the upbuilding aspect of metabolism as anabolic, and the unbuilding aspect as catabolic. If I were to compress what I have ventured to suggest to you into a formula, it would be: the thermogenic tonus of a resting muscle is dependent on a balance between the nervous impulses subserving anabolism and those subserving catabolism of thermogen. The words have a formidable sound, but I trust the idea they are meant to convey is clear enough. They emphasise the *particular* processes referred to in general terms by Dr. Broadbent in his admirably terse article in "Quain's Dictionary of Medicine." "If a theory of the febrile process is to be formed," he says, "it must be based upon a theory of the relation between the nervous system and the processes of nutrition and oxidation, and especially the latter." A few years ago such a theory of the relation of the nervous system to the processes of anabolism and catabolism would have been at best a pure speculation. Imperfect understanding of the true nature of one whole side of the relation—namely, the anabolic side—stood in the way of every attempt at demonstration. Now, however, thanks in great part to the suggestive work of my colleague Dr. Gaskell, we are beginning to have clearer light on the subject; he has given a basis of facts for a new and comprehensive generalisation, and has opened out a vista for research whose limits we cannot now estimate. I will here ask your attention only to so much of his investigation as may help us to an insight into thermogenesis.

As examples of a tonus or balance of opposing tendencies, I have mentioned, first, the tonus of the arterioles maintained by the joint continuous action of the motor and inhibitory nerves subserving contraction of the vascular muscles; and, secondly, the tonus of the respiratory apparatus maintained by the joint rhythmic action of the motor and inhibitory centres controlling inspiration. There is a third example which is hardly less familiar, though it is only of late that we have approached a consistent theory of it. I refer to the action of the cardio-motor and cardio-inhibitory nerves in maintaining the rhythmic contraction of the heart. The complicated apparatus of intrinsic ganglia, of local inhibitory mechanisms, and so on, is being gradually simplified as our knowledge of the cardiac nerves increases. Suffice it here to say that to maintain the heat at its normal rate only two concurrent and continuously acting *central* influences need be assumed. The one is exerted through the branches of the cervical sympathetic—the motor nerves of the heart. Dr. Gaskell, in his epoch-making memoir[6] on the sympathetic system, shows that we may class these nerves as functionally, structurally, and morphologically equivalent to the motor nerves of the

[5] Röhrig and Zuntz, Pflüger's Arch., 1871.

[6] Journal of Physiology, 1886.

Digitized by Google

vessels—the vaso-constrictors. The other influence is exerted through the vagus nerve, and, as we all know, its action is to check the heart's beat; when the nerve is cut the rhythm is suddenly quickened; when we stimulate the nerve the heart remains motionless and flaccid. It is the typical inhibitory nerve; it corresponds to the vaso-dilators.

But what is the nature of the influence on the cardiac muscle exerted through the motor nerve? and how does it differ from the apparently opposite influence exerted through the vagus? The characteristic effects of motor stimulation on the heart are primarily increased rhythm, increased vigour, and increased conduction of the beat through the muscular tissue. "But our knowledge of the action of any nerve is not complete so long as we only know its primary action; the chemical changes which the action of the nerve sets up in the tissue must manifest themselves in a more or less permanent after-effect, which must be recognisable apart from the more temporary primary effect of stimulation. ..... A motor nerve causes a muscular contraction by means of chemical changes in the muscle which are of a destructive nature, so that the after-effect upon the muscle is in the direction of exhaustion; and if the activity of the muscle be long continued this exhaustion becomes very manifest. ..... The subsequent exhaustion is as important a factor as the contraction." Dr. Gaskell shows that the sympathetic nerves of the heart are motor in this sense also—that their continued stimulation leads to exhaustion of its muscle. He describes such a nerve as the *catabolic* nerve of the tissue, the nerve which produces its motor effect by augmenting suddenly the destructive metabolism of the resting muscle, and thus by excessive repeated action exhausts the store of "contractile stuff" within it. What now is the after-effect of vagus stimulation when the primary and temporary effect of stopping the beat is gone by? Dr. Gaskell has shown that as regards all the functions of the muscle "the after-effect is nothing but beneficial." If before the stoppage the heart was beating at its normal rate, the rhythm afterwards is perfectly maintained or even quickened; the contraction power is maintained, or, if it was weak before, increased; the conduction power is restored if from exhaustion it was impaired: in a word, the tissue, if damaged, is repaired and restored as the result of stimulation of the inhibitory fibres. In fact, the result of vagus action is exactly opposite to that of sympathetic action: from the latter we have increased activity followed by exhaustion—symptoms of catabolic action; from the former diminished activity followed by repair of function—symptoms of anabolic action.

There is thus "no greater mystery involved in the conception of a nerve of inhibition than in the conception of a nerve of contraction. In the former case, the cessation of function, the relaxation of tissue, is a symptom of constructive chemical changes going on in the tissue—that is, of anabolism, or assimilation, or trophic action,—in precisely the same way as the activity of function, the contraction of the tissue, is a symptom of destructive changes—that is, of catabolism or dissimilation. ..... The evidence is daily becoming stronger that every tissue is innervated by two sets of nerve fibres of opposite characters, so that I look forward hopefully to the time when the whole nervous system shall be mapped out into two great districts, of which the one is catabolic, of the other anabolic, to the peripheral tissues; two great divisions of the nervous system which are occupied with chemical changes of a synthetical and analytical character respectively, which, therefore, in their action must show the characteristic signs of such opposite chemical characters. ..... The decisive proof that inhibition is a symptom of anabolism in the same way as contraction is a symptom of catabolism will, in all probability, (first) be found in the heart; and perhaps the most important investigation that must be done before this theory of anabolic nerves is based on an absolutely firm footing is to find out what are the electrical and thermal changes in the heart muscle which accompany the stimulation of its inhibitory nerve fibres." Since this was first written a remarkable confirmation of the doctrine has been obtained. When the motor nerve of a quiescent muscle is stimulated, the contracting muscle assumes an electrical condition different from that of the uncontracted—the *negative* variation. Dr. Gaskell finds that when the inhibitory nerve of a piece of quiescent heart muscle is stimulated, the muscle exhibits an electrical change of precisely the opposite character—a decided *positive* variation. He is now at work on the thermal changes accompanying inhibition, and the next news I expect to hear is that, as on stimulating a motor nerve we have a simultaneous evolution of heat, so on stimulating the inhibitory nerve the muscle becomes cooler.

It seems to me that from the considerations advanced in this lecture it is not rash to proceed to a provisional generalisation. It is this: that not the visceral and vascular muscles only, but all the muscles of the body, have their double nerve-supply. The one set of fibres are essentially catabolic; they set up disintegrative changes in the muscle, which are manifested first by thermogenesis, and secondly by contraction. The other set of fibres, whose path is perhaps anatomically different, are essentially anabolic; they set up reconstructive changes in the muscle, which are manifested by inhibition of motion on the one hand, and the absorption of energy on the other. Does the motor fibre also subserve the thermogenic function? Does the same catabolic nerve convey the stimulus which determines motion and the stimulus which determines the evolution of heat? Or are the stimuli only quantitatively, not qualitatively, different? Or again, as I have suggested, is the stimulus the same, but the "stuffs"—contractile and thermogenic—different, one impulse starting two kinds of catabolism, as when the same electric spark simultaneously fires a mixture of two explosives? These questions are as yet unanswered, though I am persuaded that the answer is not far off. Meanwhile we have brought our argument to this, that the heat production in the muscles, the chief furnaces of fever, is probably carried on under the influence of a twofold nervous mechanism: the one part exciting to thermogenesis, accompanied by destructive metabolism; the other staying thermogenesis, and subserving constructive metabolism. The thermogenic tonus is the manifestation of the normal balance between these two parts. In other words, the character of the nervous mechanisms subserving heat loss is paralleled by an analogous twofold character in the nervous mechanism subserving heat production. The relations of this nervous mechanism to the central nervous system and to the thermotaxic mechanism will occupy us in the next lecture.

ABSTRACT OF

Lectures

ON THE

ACTION OF NERVE CENTRES AND MODES OF GROWTH.

Delivered at the Royal College of Surgeons, February, 1887,

BY FRANCIS WARNER, M.D., F.R.C.S.,

HUNTERIAN PROFESSOR OF COMPARATIVE ANATOMY AND PHYSIOLOGY AT THE COLLEGE.

LECTURE III.

THE STUDY OF PATHOLOGY.

IN studying any fact in physiology or pathology, as in studying any scientific problem, we must first describe it in exact physical terms, such as connote what may be observed. In giving descriptions for scientific purposes it is advisable to avoid using metaphysical terms, as also to avoid speaking of pathological states as special entities. Let us then seek to describe pathological states in terms connoting facts capable of observation. The work in hand is divided into two parts—to describe facts, and to seek their explanation in the antecedents and sequents of these facts. The importance of pabulum and its supply in bringing about pathological processes has often been insisted on. I would insist on the equal importance of the forces or stimuli incident to the subject observed as necessary factors in determining the action in it.

There are two great classes of pathological facts—those indicated by movements (conveniently called "kinetic"), and those indicated by acts of growth (conveniently called "trophic"). The results of movements are postures, which may be represented by casts or drawings; the results of growth, normal or abnormal, may be preserved in the

Digitized by Google

museum. If the pathological fact to be studied is kinetic, either active or in a state of equilibrium, we analyse it as we analysed movements and postures, and it will then be found that in many cases both healthy and pathological characters often depend upon the antecedents, upon the surroundings, or upon the sequents, rather than upon the intrinsic attributes of the action. Similar relations between normal and abnormal acts of growth will be demonstrated. There is a very prevalent and apparently well-founded opinion among biologists and pathologists that the modes of action termed "reversion" are potent factors in the production of many of the conditions termed "pathological." This idea has principally guided investigation concerning the action of the nerve system and the origin of morbid growths.

I shall not attempt to prove any view, but put forward an hypothesis for the purpose of illustrating what I believe to be the advantages derived from the definite observation and study of movements. The theory may be advanced that "chorea is a condition of the brain analogous to that found in healthy infancy, such brain state occurring at a period of life when the force, generated by nutrition, is greater than in infancy." A reversion has been defined as a repetition of a series of movements or trophic acts, similar to a series previously existent; the criteria indicating similarity have also been defined. The child can never again become an infant, but it may become "infant-like"; its body is heavier and larger than that of the infant; its quantity of nutrition and movement are greater. In chorea the reversion is indicated by a repetition of the ratio of the attributes of the infantile state; the ratio of kinesis to weight is repeated; it is infant-like in the ratio of kinesis to trophic action. The nerve centres are observed at two periods of life—infancy and childhood; comparison is made as to the quantities and time of their action. Observation shows the combinations of movements in the infant and in the choreic child to be similar; there is said to be similarity as to the parts and their order of acting. The quantity of movement depends upon brain nutrition; the total quantity of nutrition may roughly be estimated by the weight of the body—say 15 lb. in the infant and 45 lb. in the child; the nutrition, then, in the child is three times as great as in the infant; if the ratio of kinesis and nutrition were maintained during development there would be three times as much movement in the child as in the infant. I believe this is not usually the case, but as development advances kinetic action is lessened in its ratio to other functions. We say that in health the ratio of kinetic action to nutrition lessens as growth proceeds; if this ratio reverts to that of infancy there will be an amount of movement altogether abnormal. It seems to me that this reversion to the infantile ratio between nutrition and movement is what we observe in chorea. Lessened nutrition tends to produce reversion; in chorea the weight falls, and the condition is not removed till it is restored to near the normal; mitral regurgitation tends to produce irregular supply to the brain.

Coma may be described in terms of lessened movements and reflexes. All movements may be absent, except those of organic life; the head is not turned towards a source of light or sound; the word of command and pressure on the chin are not followed by protrusion of the tongue; there may be subsultus tendinum. The arm held passively free falls into the posture of "the feeble hand."[1] [Further illustration was given by a comparative study of hemiplegia and hemispasm.] The nerve-muscular area is the same in each. The decrease of quantity of motion in hemiplegia is proportional to its increase in hemispasm, in the small and large parts respectively. Fatigue and exhaustion of the brain-muscular power on both sides is common; if, however, one side of the body or one limb be powerless, there being no evidence of organic disease, then the state is often called "hysteria." It appears, then, that a bilateral diminution of nerve force of short duration is less pathological than a one-sided weakness. In observing patients as to their movements and postures, note the action of small muscles—e.g., the interossei, causing lateral movements of fingers, as distinguished from flexor movements produced by larger muscles.

[Asymmetry of action was then dwelt upon; it was suggested that lateral curvature of the spine often commences thus. A *nervous child* was described.] Let the child stand up, and observe the conditions of growth, make of skin, the form of features; he is often too tall and too thin, the face being less emaciated than the body. Let the hands be held out; the left upper extremity is usually at a lower level; "the nervous hand posture" is probably seen on either side, perhaps more marked on the left. There may be finger twitching, with flexor or lateral movements; the spine is arched too forward in the lumbar region, often with slight lateral curvature. The face as a whole is usually too immobile, but there may be twitchings of face, eyes, tongue, &c.; the head is often flexed with inclination and rotation to the same side. The teeth are often ground.[2]

It has been demonstrated that ratios of growth have much to do with the character and results of acts of growth; we are thus led to seek examples where the pathological character of growth is due to the ratios of action. We saw that many forces can regulate proportional growth; they will be seen in some cases as the antecedents of pathological processes. Hypertrophy or over-growth may be due to an extra supply of blood, as seen in Hunter's specimen of a spur transplanted into the comb of a cock. Growth may be lessened by pressure, as in a Chinese foot, and in atrophy resulting from pressure. Hypertrophy may result from pressure, as in the large heart accompanying arterio-capillary fibrosis. The leaf-stalk of Solanum jasaminoides becomes thickened by pressure when it has twined round a support. Nerve force may regulate the quantity of growth. In anterior poliomyelitis the muscles waste; occasionally in hemiplegia the paralysed limb remains shorter in a child. It has been said atrophy follows disuse of parts, and that hypertrophy results when they are much used. [It was argued that muscles often become atrophied when they receive too little stimulus of nerve force, and that when strongly stimulated by incident nerve currents their growth is increased thereby; cases and examples were given in support of this view.] It is necessary to inquire in this place, what is meant by "the use and disuse of parts." The phrase is usually applied to voluntary action, which is followed by increased growth; lessened growth follows from lessened stimulation by the nerve centres in disuse. In anterior poliomyelitis the muscles waste because not stimulated; in hysterical palsy they do not waste because nerve-currents do reach them, though not in quantity sufficient for motion. [Certain crustaceans from the mammoth cave were shown whose eyes had been lost from their long residence in darkness; other members of the species, living in light, had perfect eyes.] What is called voluntary action appears to produce more growth than chorea, athetosis, &c.; it is probable that in the former cases the stimulation is greater.

We may next proceed to demonstrate that many unusual or pathological cases of growth may be due to the ratios or quantities of growth. In the signs of old age we see altered proportional growth; those first mentioned are almost normal to the time of life; the latter are clearly pathological, as tending to destroy the life of the individual. At the approach of old age we see diminished growth; atrophy of the hair of the scalp, the skin, muscles, and the heart, while fat may either be absorbed or may accumulate about the abdomen, &c. At the same time increased quantities of growth may occur in the prostate, and in the hair bulbs of the chin of the female; while in some cases overgrowth is further seen in the development of epithelioma, sarcoma, and cancer. [Examples were then given showing the results of varying ratios in the growth of different tissues.

Passing on to consider the causes of curvature in rickety bones, it was suggested that some are produced by mechanical strain, while others are due to unequal bilateral growth of the shafts.] Curves which are only exaggerations of the normal curves, and which are symmetrical, are probably due to unequal bilateral growth; such are seen in children who have never walked and whose muscles are very feeble. Further, in such cases the skull is often defective in form, being a bony growth, but slightly acted on by muscles at the part most misshapen. [It was shown that Glisson put forward very similar views, and facts concerning the growth of stems of plants were used as illustrations of the hypothesis. Defects in proportional growth are often seen in teratological specimens; various specimens were shown in support of this statement. In some cases there was a history of inheritance of the deformity. It was argued that the inheritance was rather that of a stimulus to nutrition than of the pabulum; while in the case of an hypertrophied kidney when its fellow had been destroyed by calculus, it

[1] See Physical Expression, International Science Series, chap. ix.

[2] See Analysis of Fifty-eight Cases, Brit. Med. Journal, Dec. 1879.

Digitized by Google

was an example of altered proportion of growth from over-supply of blood. Cases of coincident deformities were given, and it was shown that often the brain is likewise defective.]

Analogies may be made as to the distribution or seat of the parts affected by a pathological process. Many skin diseases are maculated, affecting small loci of tissue symmetrically or asymmetrically distributed. Among young infants, in the spontaneous movement of many small parts, we have evidence that separate scattered loci of brain tissue are in action. Some processes are considered pathological when asymmetrical, but not so when symmetrically distributed. Sunburn is normal; freckles are less so; one-sided pigmentation is abnormal. *Time* is an attribute of acts of growths that may give them an abnormal character—as late or irregular dentition, the development of pubic hair before adolescence, premature ossification of the skull, &c. These various considerations lead us to study the forces which control the time, quantity, and kind of growth—e.g., the effects of light, pressure, or mechanical irritation, &c.

[In conclusion, it was shown that motor actions may be described in terms of time and quantity of movements, and growth in terms of time, quantity, and kind of action in the component parts, and evidence was advanced that the attributes which give special characters may be controlled by physical forces.]

Inaugural Address

DELIVERED BEFORE THE

OBSTETRICAL SOCIETY OF LONDON,

BY JOHN WILLIAMS, M.D., F.R.C.P.,

PRESIDENT OF THE SOCIETY.

GENTLEMEN,—I thank you for the honour you have done me in electing me to this chair—a chair which has been occupied by the greatest and best physicians practising obstetric medicine in this country—an honour the greatest which the Society can confer on any one of its members. In accepting this high position, I feel I undertake a great trust; for the work of this Society has had, has now, and should always have, a great and beneficial influence upon the progress of the science and the practice of the art for the cultivation of which the Society mainly exists. I am, however, encouraged by my knowledge of the character of the officers associated with me in carrying on the work of the Society, as well as by my knowledge of the Fellows of the Society, alike those who are regular attendants at its meetings, and those who contribute to its Transactions and take part in its discussions. I feel sure that I shall not fail of the help of all.

My first duty on taking this chair is to address you—to deliver an inaugural address, and I at once confess at the very outset that I have been perplexed and in difficulty. It would have been no easy task to have written a contribution of a scientific character for discussion by the Society. Whenever I have ventured upon such an undertaking, it has been with diffidence, and misgiving of the thoroughness of my clinical and pathological observations, as well as of my knowledge of the work of those who had preceded me; but on those occasions I have been buoyed up by the feeling that what I was about to bring before the Society was brought there to be tested, put to the proof, subjected to your criticism, which I have always found to be not only gentle, but generous also. To night, however, the circumcumstances are changed. I have to speak *ex cathedrâ*, and this fact naturally does not give me greater freedom, but rather increases my difficulties, for I feel that my utterances cannot be corrected by your better wisdom. After the many able and learned addresses which have been delivered from this chair in the past, addresses which embrace almost every topic of temporary or permanent interest in connexion with obstetric practice, it would have been difficult for me to find a new theme for my discourse—unless, indeed, I had chosen to discuss a purely scientific subject; and it would have been equally difficult for me to tell you anything new about an old one. On occasions like the present, however, it cannot be amiss to take observations and determine the place to which we have steered or drifted; and I would look back, not at the history of this Society and its work only, but at the history and progress of obstetric science and practice, and I would do this not merely with a view to recount our triumphs, to survey our acquisitions, and lose ourselves in admiration of our brilliant achievements, but—which may perhaps prove more profitable—to recall to mind our defeats and failures, inquire into the causes of our disasters, and hold up to the light our errors in the past, so that they may prove of some use at least as beacons to point out the places where we departed from the path of truth, and to warn us against the will-o'-the-wisps which have been but too often mistaken for the light of science. I would look around with a view to examine the position we at present occupy, and I would look forward with the object of planning the best course for our progress in the future. As it would be impossible for me in the time at my disposal to discuss these subjects even in the briefest manner, I shall confine myself to a few observations which appear to me to be not uncalled for at the present time.

Obstetric medicine is divided into two branches—midwifery and the diseases of women. Great activity has been shown in both branches during the last thirty years, and great progress has been made. The estimate which is generally made of this progress is, however, of a one-sided character. The progress of midwifery has rarely been referred to; it has been overlooked, though not entirely; and yet to an impartial judge there can be no doubt about its extent and character. Indeed, to my mind, and to the minds of those who regard the saving of life as the crown of our work, the progress of our knowledge in midwifery has been far greater than in the diseases of women. Our knowledge of the use and application of the forceps, of the mechanism of labour in distorted pelves, and of pelvic measurement, and the means at our command for abolishing craniotomy, have saved many lives. And what shall I say of the introduction of antiseptics into the practice of midwifery? Forty years ago Semelweiss issued a few rules to be observed by the students attending women in labour in the Vienna Hospital. This proved to be the beginning of the greatest and most beneficent practice introduced into our department of medicine in this century. The work begun by Semelweiss has been crowned by the researches of Pasteur and Lister, and to-day we are in possession of the means to prevent the greatest scourge that afflicts lying-in women. When we compare the number of women who pass through the danger of childbed with that of the fit subjects of obstetric surgery, the latter sinks almost into insignificance, and the magnitude of the means placed in our hands for the prevention of puerperal fever looms high above that of all other possessions of the obstetric physician. I fear that this has been too little recognised by all who attend midwifery, for the strict use of antiseptics confers an infinitude of blessings upon the physician and upon his patients.

If we cast a glance at the history of that branch of obstetric medicine which deals with the diseases of women, the fact which strikes us first of all is the marked change which has come over it during the last thirty years—the surgical character which has been given to it. I am not going to recount to you the triumphs of abdominal and pelvic surgery. It has been done often, and indeed almost periodically, by those more fitted for the work than I. Their magnitude and their beneficent character are evident to us all. But all the pelvic and uterine surgery of the past cannot be described as triumphs. Much of it has better claims upon the term "disaster." There is hardly a malady ranged among the diseases of women, from the most trifling to the most severe, from vaginismus to uterine cancer, for which some surgical proceeding has not been suggested. This extraordinary state of things prevails nowhere else, and how is it to be accounted for? Is it to be ascribed to the failure of medical science, or to the slowness with which medical treatment accomplishes its objects? Is it due to impatience and hurry on the part of the practitioner? Does it arise from a plethora of surgical genius in our department? Or may not other causes play an important part in bringing about the present phase of the practice of the diseases of women? As with the diseases of other parts of the body, many of those which affect the female pelvic organs are, we readily confess, not amenable to treatment of a medical kind, and in some of these the art of the surgeon intervenes rightly and beneficently. There are others, again, in which the art of the surgeon has been

Digitized by Google

practised in vain or with evil consequences, but which have been subdued by the skill of the physician. There are others, again, which are cured neither by the skill of the physician nor by the dexterity of the surgeon, and this fact we should not have the obliviousness to forget nor the recklessness to overlook in practice. Hitherto surgery has proved of the greatest use in the removal of excrescences and the repair of injuries. When it has ventured beyond this, has it not been productive of more evil than good?

We are next struck by the number of operations which have been devised, suggested, and practised, by the extraordinary divergence of opinion held by authorities with regard to their value, and by the number of them which have been practised for a time and then have been entirely or almost entirely discarded. This is a state of things which obtains in no other department of medicine or in the surgery of any other part of the body. The practitioners of obstetric medicine are divided and subdivided, and the various groups which they form are separated by impassable gulfs; they pursue diverging lines and continually increase the distances separating them from one another; and there is no chance of their ever meeting except by retracing their steps. What are the causes of this deplorable state of obstetric practice? Have the many operations which have been proposed and practised been based upon carefully ascertained data—data acquired by honest scientific labour? Or have they been based upon hypotheses—the offspring of a too active imagination? Or have those who have been opposed to the present surgical mode failed to appreciate ascertained scientific truths? It would not be possible for me under any circumstances, perhaps, to answer these questions fully, and now I can only refer to one or two facts which have a bearing upon the answer. The fact that many operations which have been proposed and practised have proved useless or injurious and have been discarded, indicates that such operations were proposed on insufficient and untenable grounds. This will appear beyond doubt if I remind you of the history of vaginismus and dysmenorrhœa. The operations proposed for the cure of the former have entirely failed! And how many a hypothesis has been started—with unfortunately its usual appendage, an operation—with regard to the etiology of dysmenorrhœa, and raised to the rank of a theory without even the shadow of a foundation! What disasters have they led to, and how barren of good results have they proved! There can be no objection to hypotheses as such—they are essential to scientific research; but they should be made to be tested and not acted upon, to discover truth and not to be taken for it. It appears to me that the present surgical aspect of obstetric medicine arises chiefly from the promulgation of flashy hypotheses and their acceptance as established truths. The mischief arising from the too ready acceptance of surmises cannot be exaggerated, and I will give you a further illustration of it from the other branch of obstetric medicine. About a quarter of a century ago Dr. Braxton Hicks enunciated the scientific method of treating placenta prævia. For nearly five-and-twenty years this was overlaid by a mass of teaching based upon false hypotheses and exceptional occurrences, and has only recently been rescued from beneath the mass of error and reintroduced to us through the exertions of a German explorer. Hypotheses and their ready acceptance have been the bane of obstetric science during recent years. We should prove all things, and especially hypotheses burdened with operations.

Although what I have mentioned is probably the chief cause of the surgical aspect of practice in the diseases of women, yet there are other causes for it, and I would mention one of them—namely, the wonder-inspiring character of many of the operations practised for pelvic diseases. This is the side of them which appeals to the public, and unfortunately also to a large number of the profession. Like the most dangerous feats of the acrobat, they appeal irresistibly to a quality of mind which is far from uncommon.

If we look around us and glance at the present, we find untiring activity everywhere—sometimes well directed, sometimes not. In France excellent work is being done; Germany sheds abroad the facts gathered in her large lying-in charities and her laboratories; and the Transactions of this Society and those of its sister societies in Scotland and Ireland attest the amount and excellence of the clinical and pathological work done in this country. To America we owe much that is excellent in midwifery and in the treatment of disease. In that great country much of the energy of the profession is, however, devoted to the impossible—to setting the coping-stone before the foundations have been laid. At the same time, we rejoice that many of our brethren there are devoting themselves to clinical and pathological work. But there is one phase of the work done in their obstetrical societies which I cannot pass by without an expression of regret, and that is the practice of publishing imperfect reports of operations before the results, immediate and remote, of the operations are known. I can conceive no good to result from publishing operations on a Thursday which were performed on the previous Monday. Indeed, I know of no practice so likely to be productive of unalloyed mischief. It is a practice which I trust will never be introduced into our Society. If it is intended to benefit science by it, the intention must fail; and if it be for the purpose of mere advertising, I have no words bitter enough to express my contempt for it. Were this Society a mere advertising medium, I would neither hold office in it nor be a member of it for an hour. It is, however, an excellent publishing medium, and it is right that it should be such. We do not light a candle and place it under a bushel; nor do we bring new facts and new discoveries into this room to hide them, but for the enlightenment of one another and of the profession. My faith in this Society and my hope for its future are not based upon its excellence as an advertising medium, but upon the number of the scientific workers among its members. These are increasing, as is attested by the number of papers in the hands of the secretaries and the pressure on our time and space. And what is the work before us in the future? Is it the cure of disease and the relief of suffering? Yes. Is it the discovery of new drugs and their effects? Yes. Is it the improvement of obstetric surgery? Yes; all this and a great deal more. The present surgical aspect of the treatment of diseases of women is surely destined to pass away; it cannot be permanent. Were it otherwise, we should have to confess that medical science has proved a failure. Mutilation is not the highest goal to which medical and surgical skill can reach. A time will come when obstetric science will assume a preventive character. Although we cannot hope to abolish disease, yet we may be able to discover the means of preventing it, and perhaps of curing it without the aid of surgical art in its present mutilating character. We are already possessed of the means of preventing a large number of the chronic diseases and sufferings of women in the application of antiseptics to midwifery. This gives us the control of a large class of the inflammatory affections of the pelvis. Forty years ago the idea of preventing or abolishing puerperal fever and puerperal inflammations would have been scouted as Utopian, and who knows but that forty years hence some president of the Obstetrical Society may not be able to announce to his audience that obstetricians of that day possessed the means of preventing the growths of ovarian tumours or of fibroids or of cancer?

The progress of our science is not to be limited. It is not to be made, however, by happy guesses, but by steady work, and in no long time by co-ordinate work. Facts of all kinds, great and small, are to be accumulated. The present surgical activity would, if rightly employed, prove of service in bringing about the time I anticipate, and its own extinction, by making known facts which cannot well be otherwise discovered. No operation should be performed for cure simply, but also for investigation. No operation should be performed without a reasonable chance of cure or relief. Many of the operations now performed can be reasonably regarded as experiments only. If they can be justified at all, they can only be justified when done under the strict conditions of an experiment. Unfortunately, however, we know but little of the real results of operations of doubtful utility. But the help of surgery of a debatable character is not the only or chief means of sound progress. This has always been, and will be in the future, the result of patient watching by the bedside and careful observation of disease extending over years, and by continuous work in the laboratory. It will also be the work of the profession as a whole. It cannot be accomplished by the hospital and consulting physician and surgeon alone; it requires the help of the family doctor, of the town doctor, and of the country doctor. Each one has his work to do. As a rule, passing phases of disease only come under the observation of the hospital physician, while the whole course of it passes under the eye of the family doctor. Many of the diseases peculiar to women are of a very chronic character, and, as in other branches of medicine, their source is to be sought in antecedents long passed which come under the ken of the family practitioner only. But the country doctor has his part to do in this work. It is only by

Digitized by Google

research everywhere, in town, in country, in patients of different occupations and different constitutions, that the necessary facts can be obtained, and the country doctor is in this respect placed at an advantage over his town brother, although in other respects he may be placed at a disadvantage. This Society should gather facts from all quarters and from all sorts of practitioners—all kinds of facts bearing on health and disease. I have pointed out to you fields where each one of you may by patient work attain distinction and become contributors towards the progress of the science which we cultivate. To this work I invite you, and while I occupy this chair I shall welcome with equal partiality every fact—the smallest and the greatest—which is calculated to contribute towards the object which we have in view.

PYREXIA AND HYPERPYREXIA.

BY T. J. MACLAGAN, M.D., M.R.C.P.,
PHYSICIAN IN ORDINARY TO THEIR ROYAL HIGHNESSES PRINCE AND PRINCESS CHRISTIAN OF SCHLESWIG HOLSTEIN.

(*Continued from page 519.*)

WITH distinct evidence that paralysis of certain parts of the body may occur without any organic lesion to account for it, there is no ground for claiming for the thermic centre immunity from such disturbance, and there is much evidence to show that it enjoys no such immunity. With that evidence we have now to deal. We shall consider it as it presents itself in hysterical pyrexia, in the hyperpyrexia of heat apoplexy, and in that of acute rheumatism.

Hysterical pyrexia and hyperpyrexia.—The name here expresses all that we really know about this condition. Cases are on record in which hysterical symptoms have been accompanied by a rise of temperature for which no explanation could be found. With distinct evidence that hysteria may cause paralysis of a limb, of the vocal cords, and of the bladder, we need have no difficulty in admitting the possibility of its causing impairment and even paralysis of the thermic centre. The essential symptom of such a condition would be rise of temperature.

Heat apoplexy results from exposure to heat. In the fully developed disease there is complete insensibility with a very high temperature; but the onset of this alarming condition is generally preceded for some days by headache, giddiness, restlessness, or other evidence of disturbance of the nervous system. That continued exposure to a high temperature is likely, in a native of a temperate climate unaccustomed to such exposure, to cause disturbance of the thermal apparatus there can be no doubt; and a brief consideration of the mode in which this disturbance is likely to be brought about makes it apparent that such exposure, if sufficiently great or long continued, may cause paralysis of the heat-inhibiting centre, and consequent great rise of temperature. Heat is an excretory product requiring to be eliminated; its main channel of elimination is the skin; a high temperature of the atmosphere necessarily interferes with such elimination, because in such an atmosphere heat cannot readily be thrown off. Heat elimination being thus checked, and heat production continuing as usual, heat must accumulate in the system, unless some agency steps in either to increase the former or diminish the latter. Under ordinary circumstances nature provides the remedy; for the same atmosphere which makes heat elimination difficult causes also increased activity of the skin, and so to some extent meets the difficulty which itself creates; while the general influence of residence in a hot climate leads to habits of life which diminish heat production: thus the risk of heat accumulation is diminished at both ends. But circumstances every now and then arise which break through these habits. Such circumstances are those which call for exposure and muscular effort during the heat of the day, as in the case of soldiers on the march. Tissue metabolism and heat production are stimulated, while the body is exposed to a temperature which makes impossible a corresponding increase in heat elimination. Under such circumstances, the only way in which the danger attendant on undue accumulation of heat can be warded off is by restraining heat production, and this end can be attained only by increased activity of the heat-inhibiting centre. Heat is the natural stimulus of that centre, and accumulation of heat in the system naturally excites it to increased effort. But the call may be beyond its powers to meet: it continues to make the effort and struggles to keep the temperature down, till over-stimulation leads to exhaustion; its efforts become feebler, and ultimately, paralysed by fatigue, it ceases to act. Thus is removed the last safeguard; heat rapidly accumulates in the system, and heat apoplexy, with its attendant hyperpyrexia, results. What takes place in the thermic centre under such circumstances is the exact analogue of what takes place in the respiratory centre, when, under allied circumstances, carbonic acid accumulates in the blood. The first effect of increase of carbonic acid in the blood is to stimulate the respiratory centre and cause increased frequency of respiration. If the gas goes on accumulating, that centre begins to show evidence of fatigue, and the respirations become slower and more laboured, the interval between them becomes wider, and finally they cease altogether, the heart continuing to beat for some time longer. The cause of their cessation is paralysis of the respiratory centre, induced by accumulation of carbonic acid, the natural stimulus of that centre. In the same way, accumulation of heat in the system causes first stimulation and ultimately paralysis of the thermic centre; and thus we explain the great rise of temperature in heat apoplexy. Post-mortem examination of fatal cases shows only a tendency to rapid decomposition, a fluid condition of the blood, and more or less congestion of the lungs.

Rheumatic hyperpyrexia.—Every now and then cases of acute rheumatism occur which, after presenting the symptoms of the malady in their ordinary form, suddenly develop alarming nervous symptoms, with a temperature rapidly rising to 108°, 109°, 110°, and even higher, and a tendency to death by coma. How is this great rise of temperature brought about? 1. It might be merely an exaggeration of the ordinary pyrexia of the disease. 2. It might result from a direct paralysing action of the rheumatic poison on the thermic centre. 3. It might be produced in the same way as heat apoplexy, by over-stimulation of the inhibitory centre, resulting in paralysis of heat inhibition, and consequent rapid rise of temperature.

A very little consideration suffices to show that the first hypothesis is not adequate. Were the hyperpyrexia of acute rheumatism merely an exaggeration of the ordinary pyrexia of the disease, cases in which it occurs would be characterised by inordinate severity of the rheumatic symptoms. But such is not the case. In cases which become hyperpyretic the disease up to the onset of the hyperpyrexia presents no unusual features. The temperature, the joint pains, the acid sweats, the heart complications, are all such as are met with daily in ordinary rheumatic attacks; and there is nothing in their symptoms to lead the physician to anticipate so alarming a complication.

The hypothesis that it may result from paralysis of the thermic centre consequent on the direct toxic action on that centre of the rheumatic poison, or some product of the rheumatic process, is one regarding which no more can be said than that it is possible. Against it may be adduced the argument that were such the mode of production of rheumatic hyperpyrexia, that condition would arise more frequently than it does. The rheumatic poison and the products of the rheumatic process operate in every case, but hyperpyrexia is of rare occurrence.

The third hypothesis is one for which more may be said, for between heat apoplexy and rheumatic hyperpyrexia there are many points of analogy. The symptoms and clinical features of both are very much alike, and the description of the post-mortem appearances observed in the one serves equally to describe those noted in the other. In each the tendency is to death by coma. Treatment, too, is the same in both. The main difference between them is in the circumstances which lead up to their occurrence. With so many points of resemblance between them we cannot but look for a common mode of production, some common pathological bond. The question for consideration is the possibility of the rheumatic process, as it exists in acute rheumatism, producing the same result as we find follow exposure to great heat. This latter acts by over-stimulating, fatiguing, and finally paralysing the thermic inhibitory centre. The question before us, therefore, narrows itself into a consideration of the point as to whether or not over-stimulation and consequent fatigue of the heat-inhibiting centre is a possible result of the process of acute rheumatism. Wide as is the difference between that process and great heat, and great as seems the improbability of two such different agencies

Digitized by Google

producing the same effect on the system, a careful consideration of the facts nevertheless leads to the conclusion that such result is not impossible. Certain it is that if overstimulation of the thermic inhibitory centre could be a result of any fever, rheumatic fever is the one in which it would most likely manifest itself, and that for the following reasons:—

In all fevers the rise of temperature results from increased tissue metamorphosis, as will be presently explained. This is the case in rheumatic fever, as it is in typhus, typhoid, and other fevers. But the circumstances under which that increased metabolism takes place in rheumatic fever are altogether peculiar to itself, and the peculiarity of these circumstances it is which leads up to the phenomenon which we are now considering—the greater tendency to the occurrence of hyperpyretic complication. Nearly every form of fever has for its essential and characteristic feature the occurrence of some local lesion—of some affection, generally inflammatory, of one particular organ or tissue of the body. The characteristic lesion of rheumatic fever is inflammation of the textures of the motor apparatus of the body. Part of this motor apparatus—viz., the muscles—is the chief seat of heat production. The more active the metabolism of the muscles, the greater the amount of potential energy produced. This potential energy may take the form of work or heat. As a matter of fact, it generally assumes the form of work, for it is when muscles are actively contracting that this potential energy is chiefly formed. But if the same metabolic changes which take place in a contracting muscle were to take place in that muscle when quiescent, the potential energy would take the form, not of work, but of heat. This is what occurs in acute rheumatism. The rheumatic poison causes a general febrile disturbance, accompanied by inflammation of the fibrous textures of the large joints. Inflammation of these textures is of course accompanied by increased flow of blood to, and increased metamorphosis in, them. Apart from the muscles with which they are connected, the fibrous tendons and ligaments have no function, no *raison d'être*. So intimately are the muscles and the textures involved in acute rheumatism connected in their function, in their innervation, in their vaso-motor and blood-supply, and in all that concerns their vital activity, that inflammation of the latter could not fail to produce in the muscles some degree of the same increased tissue change, the same abnormal metabolism, which is taking place in the fibrous textures as the result of the action of the rheumatic poison. This is not mere hypothesis, for we have distinct tangible evidence that there does occur in acute rheumatism such increased metabolism of muscle as is usually associated with active exercise. This evidence is the persistent presence in the system during the course of that disease of an excess of lactic acid. That acid is a metabolic product of muscle; it is formed in increased quantity during muscular exercise; and its constant presence in excess in the course of acute rheumatism is distinct and clear evidence that that disease has for one of its phenomena increased metabolism of muscle. It is the only form of fever in which such evidence exists. Muscle being the chief seat of the formation of heat, and the metabolism of muscle being the chief source of heat, it follows that the disease in which such metabolism is most active is also that in which most heat will be formed. That disease is acute rheumatism. Theoretically, there is thus reason to believe that heat production is more active in acute rheumatism than in any other disease; and there is also practical evidence that such is the case. The natural result of increased formation of heat is its increased elimination. The skin is the channel by which heat is eliminated. We accordingly find that profuse perspiration, the evidence of excessive action of the skin, forms one of the characteristic features of rheumatic fever. It is the only form of fever which is so characterised. Excessive production is thus met by excessive elimination of heat, and no undue rise of temperature occurs.

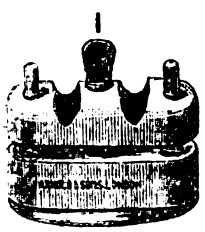
But another result of such increased activity of the heat-producing process must be stimulation of heat inhibition. The function of the thermic centre is to restrain excessive formation of heat; that function is therefore likely to be called into more active operation in acute rheumatism than in any other disease. It might happen, either from want of vigour or from unusual susceptibility of that centre, aided possibly by more or less failure in the heat-eliminating action of the skin, that heat production was in excess of heat elimination. Under such circumstances heat would accumulate in the system. The thermic centre would be first stimulated to excessive effort, then fatigued, and finally paralysed, as in heat apoplexy, and hyperpyrexia would result. That is a sequence of events which might occur in any form of fever or in any ailment, accompanied by increased activity of the heat-producing process. The more active that process the more likely is it to happen. Acute rheumatism, being the ailment in which heat is most abundantly and rapidly formed, is also the one in which inhibition is most likely to be over-matched. Hyperpyrexia is therefore more common in it than in any other form of fever.

It is evident that the neurotic theory of fever rests on a very adequate basis, and affords a reasonable explanation of the rise of temperature noted in many morbid conditions; and that it specially affords of the occurrence of the very high temperature of hyperpyrexia an explanation which, if not the only one possible, is at least more satisfactory than that offered by any other theory. But, adequate as this theory is—nay, necessary as it is—to the explanation of the rise of temperature noted in the ailments to which reference has hitherto been made, we must be careful not to let our advocacy of it carry us too far, or to try to explain by it the rise of temperature of ailments whose pyrexia can be better and more satisfactorily explained on the combustion theory. As already said, the neurotic and the combustion theories are not antagonistic. Each has its own special sphere of application. The most important and typical examples of neurotic pyrexia have already been instanced.

The maladies to the explanation of whose pyrexia the combustion theory applies are more numerous and important. To consider them all would be impossible here, and would not lead to a clearer understanding than the plan which we shall adopt of illustrating this theory by important and typical examples. For this purpose we shall take the specific fevers. They are chosen—(1) because they are the most important group of diseases to which man is liable; (2) because they are the maladies in which the evidence of increased tissue metabolism is most marked; (3) because the febrile process can be more conveniently studied in them than in any other maladies; and (4) because we know more about the nature of the cause (the specific poison) which gives rise to them than we do about the cause of most other febrile ailments, and can therefore more readily investigate its probable mode of action in the production of febrile disturbance.

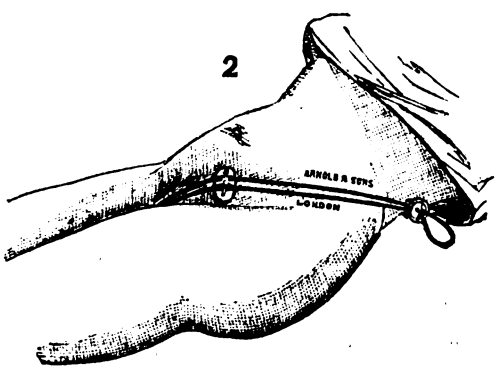
(To be continued.)

NEW PELVIC TOURNIQUET FOR AMPUTATION AT THE HIP-JOINT AND OTHER OPERATIONS.



BY JOHN WARD COUSINS, M.D. LOND., F.R.C.S.,
SENIOR SURGEON TO THE ROYAL PORTSMOUTH HOSPITAL, AND TO THE PORTSMOUTH AND SOUTH HANTS EYE AND EAR INFIRMARY.

THE recognition of the operation of amputation at the hip-joint as a surgical proceeding occurred about the end of the last century, and in the pre-anæsthetic period the effectual restraining of hæmorrhage was always a matter of difficulty and danger. During the last few years the operation has been widely practised, and various methods have been employed by surgeons for controlling the circulation through the limb. 1. Digital compression of the femoral and external iliac arteries. When the flap operation is performed, this manipulation must be entrusted to a steady assistant who can undertake to follow the knife and to grasp the end of the vessel as soon as it is divided. An operation rendered tedious from any cause is sure, however, to excite painful weariness of the hand, and sometimes even severe cramp from prolonged muscular tension. Except for operations upon children, digital compression ought now to be regarded only as an auxiliary measure. 2. External compression by means of a rigid tourniquet. For this purpose Lister's aortic compressor has been very generally employed. It consists of a bar of steel shaped like a horseshoe, having at one extremity the spinal pad, and at the other a rod working through a female screw and carrying the abdominal pad. The application of this method is certainly not free from risk. The pressure of the instrument over the centre of the



Digitized by Google

abdomen interferes with the movements of respiration; at the same time, the occlusion of the vessel by the force of an unyielding screw involves the bruising of internal structures and the dangerous compression of important organs. 3. Internal compression of the iliac artery through the rectum. The rectal lever, recently introduced by Mr. W. Davy, is a very powerful instrument for controlling the circulation, and in the hands of the inventor it has been used with marked success; still, it is my opinion that it can never receive universal adoption. The finger cannot guide the rigid extremity of the instrument, and the greatest care and dexterity are insufficient to protect the pelvic structures from the dangers of contusion and injury. 4. Elastic compression of the iliac artery over the pelvic brim, and simultaneous pressure upon the posterior vessels at the sacro-sciatic notch. This excellent method is the invention of Mr. Jordan Lloyd of Birmingham. It can be effectually carried out by one assistant, armed with a calico roller, a piece of indiarubber bandage, and a safety-pin. From my own experience, I regard this form of elastic compression as far preferable to all the other devices which have been hitherto employed for the purpose of preventing hæmorrhage during hip operations; and I venture to express the opinion that it is destined to obtain general adoption in the future.

The pelvic tourniquet represented in the engraving has been designed for the purpose of facilitating the practice of elastic compression. It is a modification of the elastic cord tourniquet introduced by me some years since. It does not require the hands of an assistant to keep it in a state of tension, and the pressure of the cords over the compressor can be regulated with great exactness. The instrument consists of three parts: 1. A metallic clamp by which the cord is instantly tightened and loosened. 2. An endless elastic cord with a mark at the spot where the clamp is to be attached to it. 3. An iliac compressor consisting of a well-padded wooden block, with grooves on its upper surface for holding in position the elastic cords. (See Fig. 1.) The compressor can be elevated and depressed by the

1

2

action of a central screw and two powerful recoil springs. (See Fig. 2.)

The method of application is very simple. After fixing the clamp on the cord, and emptying the limb of blood by elevation and friction, the patient must be turned over to the opposite side, so that the cord may be accurately adjusted, and the abdominal organs displaced out of the way of the compressor. The centre of the elastic ring is now inserted between the thighs—one loop is passed behind the tuberosity of the ischium, while the other loop, carrying the clamp, is placed in the grooves on the compressor. Both loops are now drawn upwards and outwards, and when they are sufficiently tightened the clamp is shut above the crest of the ilium. The external iliac artery can now be completely occluded by releasing the screw, at the same time the posterior vessels are controlled by the cords at the sacro-sciatic notch. Sometimes it will be found convenient to place the compressor in position under the cords after the closure of the clamp. The pelvic tourniquet is neatly made for me by Messrs. Arnold and Sons of West Smithfield.

Southsea.

THE INFLUENCE OF ALTITUDE ON PHTHISIS.

BY NATHANIEL ALCOCK, L.R.C.S.I.,
SURGEON-MAJOR, MEDICAL STAFF.

IN the third volume of Professor Hirsch's great work, "Handbook of Geographical and Historical Pathology," it is shown that while the influence of latitude upon phthisis is scarcely appreciable, that of altitude is most striking. The explanations hitherto offered of the action of altitude upon phthisis amount to three: greater expansion of the chest from aerial rarefaction; absence of bacterial organisms from the air; and general tonic effect.[1] Were the first of these effective, some improvement would be expected to follow the use of gymnastics at lower levels; of the second it may be said that every consumptive carries his own microbes with him; and the third is too vague to need discussion. It may therefore be assumed that no satisfactory explanation has as yet been suggested. The specific organism of tubercle has an established identity; consequently, the disease must be ranked among the special infections, and its aggravation or arrest must depend upon the fertility or sterility of the microbe to which it is due.

Pasteur, in his splendid researches on the poison of splenic fever, has shown that "splenic fever can never be taken by fowls; in vain are they inoculated with a considerable quantity of splenic blood." "Now, the temperature of birds being between 106° and 108°, may it not be," said Pasteur, "that the fowls are protected from the disease because their blood is too warm? A hen was taken, and, after inoculating it with splenic fever blood, it was cooled down to 100°. At the end of twenty-four hours the hen was dead. Again, a hen was inoculated, subjected like the first to cooling, and when the fever was at its height it was wrapped in cotton-wool and placed in an oven at 95°. In a few hours it was fully restored to health. Hens killed after having been thus saved no longer showed the slightest trace of splenic organisms." Thus it is proved that the microbe of one of the most virulent diseases reaches its condition of highest life and greatest reproduction in blood at a temperature of about 100°, but that in the same blood at 107° it ceases to exist. Presumably, then, if the subjects of some forms of bacterial infection could survive a proportionate elevation of temperature, they too would overcome the poison.

The question here arises, Are there any conditions in which the blood of a living man can be made to assume the molecular action equivalent to a temperature of 105° while the animal heat remains at 98°? Clearly such is quite possible by diminishing atmospheric pressure while the temperature remains fixed. We know that it would be quite impossible to boil water at the sea level with 199° of heat, but that if the water be removed to St. Gothard, 6808 ft. high, boiling will at once take place. Professor Thomson, in his opening address at the British Association, said: "It is scarcely possible to help anticipating in idea the arrival at a complete theory of matter, in which all its properties will be seen to be merely attributes of motion." It is already accepted that the only difference between the liquid and gaseous states is that of molecular motion. Consequently, if 199° of heat can make water boil at St. Gothard, it is apparent that this temperature can there produce an amount of molecular motion which not less than 212° could excite at the sea level. Further, as 199° is to 212° so is 98·4° to 104·8°; therefore the rate of molecular motion to which a temperature of 98·4° would give rise at St. Gothard could only be attained at the sea level as the result of a temperature of 104·8°.

Professor Clifford has shown that "the energy of the single particles is always proportional to the temperature of the gas," provided the pressure remains unaltered. Consequently, since the condition of every organism is but the aggregate of its ultimate atoms, if a man whose temperature at the sea level is 98·4° be removed to St. Gothard, it is evident that both the gaseous and liquid molecules in his blood must attain a rate of motion corresponding to what would have been produced at sea level by a temperature of 104·8°. But the experiment of Pasteur has demonstrated that the optimum temperature of certain infecting organisms is about 100°, and that when the vibration-rates equivalent

[1] THE LANCET, Jan. 8th, 1887.

Digitized by Google

to 106° or 107° are communicated to their constituent molecules, disorganisation follows. Hence it is intelligible that, if a consumptive patient whose temperature at sea level is 98·4° be raised to an elevation of 6000 ft., such alteration of molecular motion will take place in the blood as to be incompatible with the healthy existence and effective reproduction of the tubercular microbe; in fact, the patient will be placed in the position of the bird to the splenic fever poison. If this reasoning be sound, wide is the vista with regard to the epidemic levels of yellow fever, malaria, cholera, &c., which it must open up, and strange the possibilities which might result from the artificial production of the required conditions.

Military Prison, Dublin.

ONE HUNDRED CONSECUTIVE CASES OF ABDOMINAL SECTION.

BY GEO. GRANVILLE BANTOCK, M.D., F.R.C.S. ED.,
SURGEON TO THE SAMARITAN FREE HOSPITAL.

(*Concluded from page 481.*)

Hydatids of the peritoneum.—The patient was a young single woman, aged twenty-five, by occupation a cook. When admitted in May, 1886, she gave the following history. She had been aware of "a lump in the stomach" for six or seven years. Three years and a half ago she had retention of urine, which was relieved by passing the catheter two or three times. She then entered a suburban hospital, where she was told she had a tumour. Nine months ago she had a child, and since that time the increase in the size of the tumour had been very marked. On opening the peritoneum, it was at once evident that I had to do with a case of hydatids—which I may say was suspected. The incision was enlarged to about 4 in. to admit of extraction of the different tumours before separating them from their connexions with the omentum, &c. I began by breaking down the connexions of the largest cyst, but they were so firm and the bleeding so great that I was obliged to resort to the method of ligaturing first and then cutting. In all, I removed about half a dozen cysts of various sizes, from that of a hen's egg to that of a small cocoa-nut. One of medium size occupied the right half of Douglas's pouch, where it hung pendulous with a slender attachment to a tag of omentum, where it was felt before operation, and regarded as an enlarged ovary. Down in the left iliac region, one, as large as an orange, lay amongst the coils of intestine. On seizing the exposed portion of the cyst wall between the finger and thumb, it at once gave way, and many daughter cysts, from the size of a pea to that of a walnut, escaped amongst the intestines and were with difficulty recovered. That one eluded my search was evident from the fact that at a subsequent period a small collapsed sac came away through the tube-hole. The cyst wall was so friable that it could only be detached from the intestines by means of the sponge. A small cyst was attached to the edge of the liver, and there was a larger one on the under surface of the liver, very far back. As it would have been impossible to drain these if opened, I let them alone. After thoroughly washing out the peritoneum a drainage-tube was inserted, and the patient made a good recovery. She is now in excellent health and able to follow her occupation. Nor is there any increase in the liver cysts. The weight of the cysts exceeded 2½ lb.

Retro-peritoneal cyst.—This tumour occurred in the case of a young lady aged fifteen, who came under my notice about the end of January last, having been sent to me by Dr. Robson Roose. The tumour had been observed for about eighteen months, and when first discovered was about the size of a Mandarin orange. During this time the patient was subject to attacks of severe pain, often accompanied with fever, the temperature sometimes running up to 105°. There was much bewildering consultation over the unfortunate patient, and the case forcibly illustrates the remarks made by Mr. Lawson Tait in a paper read before the Medical Society of London on Nov. 8th last, when he denounced many consultations with physicians over surgical cases as farcical proceedings. At last, however, Sir Joseph Lister agreed with me as to the propriety of surgical interference, on the ground that there was distinct evidence that the tumour was growing rapidly. Accordingly it was removed on Feb. 16th, 1886, the incision along the outer border of the left rectus muscle extending about an equal distance above and below the umbilical level. The tumour was covered by the mesentery, whose vessels were enormously enlarged, and it lay just over and in close contiguity to the left kidney, for which it was mistaken, owing to the impulse communicated to that organ on bimanual palpation, and it pushed the splenic flexure of the colon towards the umbilicus. Many ligatures were required in the course of the enucleation, the vessels being doubly secured before division; and, finally, the greater part of the sac was cut away after the application of a double stout ligature. A drainage-tube was inserted, as there was still some oozing from the remaining torn surfaces. The patient made a good though tedious recovery, owing to the occurrence of some superficial suppuration in the track of the drainage-tube. The temperature only once reached 100·8°, and was above 100° for only one day. The patient is now quite well. The tumour weighed over 1 lb. It is now in the museum of the Royal College of Surgeons. Mr. Eve kindly furnished me with the following report:—"The tumour is composed of a number of inter-communicating loculi, separated by numerous septa, and contained a glairy mucoid fluid. I am quite at a loss to explain its origin, the situation being so unusual, and only conjecture that it originated from some fœtal structure, possibly some of the rudiments of the permanent kidney; it was too high for the Wolffian body. The other possibilities that occur to me are that it was an ovarian cyst which had become separated by twisting of its pedicle, or that it was of the same nature as the cysts which have been found in the great omentum." I take Mr. Eve's first idea as probably the correct explanation of the origin of this remarkable tumour. It was situated too much behind the mesentery for an ovarian tumour which had become separated from its natural attachments, and its relations in no respect resembled an instance of that kind which occurred in my practice in October, 1884, in which I removed a small ovarian tumour from the right side of the abdomen, and whose pedicle had been severed from the *left* side.

Incision and drainage.—A married woman, aged thirty-seven, the mother of three children, the youngest of whom was eight years old, was sent to me by Dr. Amand Routh. There was a history of acute disease within the peritoneum in January last, with uncontrollable sickness for two days, severe pain for five days, and fever. At the end of February she was tapped of over half a gallon of a thickish, pale-yellowish fluid. In another month she was again tapped of three pints of a thicker fluid of the same appearance, and was recommended to apply poultices over the abdomen. In a few days the puncture hole began to discharge a thick puriform fluid. After three months' confinement to her bed she began to get about, and at the end of May came under the care of Dr. Routh in the out-patient department of the Samaritan Hospital, but I was unable to admit her until the end of July. She was then in a very emaciated condition; the puncture hole was still open, but only occasionally discharging. An ordinary surgical probe was passed in to its full length, but nothing came out on its withdrawal. I therefore thought I had to deal with a multilocular tumour suppurating in its centre loculus, and I was not a little surprised in the operation that when the parietes were divided I opened direct into a single cyst filled with a purulent-looking fluid, to the amount of about four pints. After washing out the cavity till quite clean with simple warm water, the cyst wall was seen to be lining the whole pelvic cavity, the intestines having been pushed out and the uterus pressed forwards and downwards; in fact, looking into the pelvis was like looking into a hat. It was therefore evident that this was not a case for further interference, and I accordingly closed the wound and left in a drainage-tube, and for the purpose of excluding air I filled up the cavity with warm water. After forty-eight hours, when there was a slight odour from the discharge, the cyst was washed out with sulphurous acid several times daily, and the odour at once disappeared. Whilst the temperature previously to the operation daily rose towards evening to 102°, it remained perfectly normal afterwards. In fifteen days she went to a convalescent institution, and in a few weeks more returned home. She presented herself at the hospital in November in perfect health.

Exploratory operations.—The list of seven includes nearly as many different conditions. In the first case the whole

Digitized by Google

peritoneum was studded with sago-like granulations, and the patient was much benefited by the removal of the fluid. When last seen, three months after operation, the fluid had not reaccumulated. The diagnosis made was "probably malignant disease." Whether this was correct, or whether the disease may turn out to be of a non-malignant nature, remains to be seen. It is, however, a singular fact that whilst tapping in these cases is always followed by a rapid reaccumulation of the fluid, the operation of abdominal section has been followed, in my experience, by complete immunity, even in cases that have proved fatal in a few months, from the progress of the initial disease.

The second and third were instances of supposed tubal disease: one of the patients being a young married woman, aged twenty-five, with two children, the youngest being six months old; and the other aged forty-six, with one child aged twenty-five. In both cases the adhesions of omentum, and especially of intestine, over the pelvic contents were very extensive, and so firm that there seemed no possibility of reaching the pelvis without rupturing the intestines, and after stopping the oozing from the ruptured adhesions by means of ligatures and the pressure of sponges the wound was in each closed. I have seen the latter of these cases quite recently, and while at the time of the operation, in November, 1885, the uterus was quite fixed in the pelvis, with considerable surrounding tumefaction, it is now quite mobile and the swelling has almost disappeared. This result would seem to disarm criticism directed against the non-completion of the operation, especially as the patient is already so advanced in years, and yet the attempt appears to me to have been justified by the physical signs and symptoms existing at that time.

The fourth case was one of papilloma extensively involving the left broad ligament, and the operation confirmed the diagnosis. The patient was a married but sterile lady aged fifty-six. She had been tapped three weeks previously, and the fluid had rapidly re-formed. Abdominal section was performed with the view of taking advantage of the curious fact to which I have just referred, and in this I was not disappointed; for while the patient was under my observation—three weeks—there was no reaccumulation of fluid. How long that might have been the case cannot now be determined, as the patient died a few weeks afterwards of an acute pulmonary disease.

In view of Mr. Doran's paper, recently read before the Obstetrical Society of London, on "Papilloma of the Fallopian Tubes," I may here state that I am inclined to believe that many, perhaps the majority of cases in which we find this form of disease, are instances in which the papilloma, taking its origin within, has burst through the tube and then spread itself over the broad ligament and adjacent structures. The last case I shall refer to (the second in the paper above noticed) appears to support this view, and if it be correct, then papilloma of the tube is not so uncommon as Mr. Doran's researches would lead us to suppose.

The fifth case is one of very great interest. On Dec. 8th, 1885, I was asked by Mr. Tapson of Clapham to see Mrs. R——, aged thirty-eight, the mother of two children, of whom the youngest was seven and a half years old. The history was as follows:—For the last year she had been "generally out of sorts": menstruation, previously normal, had become very irregular, with intervals of two and three months, and the last period occurred in the end of August. By the end of September she began to complain of pain in the right groin, which had gradually become very severe. She therefore consulted Mr. Tapson in November, and he, finding a small tumour in the right ovarian region, requested me to see her. On examination, a tumour, the size of a large orange, was found on the right side of, and closely attached to, the uterus, tender on palpation, non-fluctuating, but elastic. The fundus uteri could be distinctly defined. There was nothing characteristic in the condition of the cervix. As the result of this examination, I gave it as my opinion that the disease was either an enlarged ovary very closely attached to the uterus, or an affection of the (right) Fallopian tube, and I advised that Mr. Tapson should watch the case. By the beginning of January the pain had become so severe, coincident with an enlargement of the tumour, that he requested me to take her into the hospital as soon as possible, and she was admitted on January 11th. I was at once struck with the great change that had taken place in the local condition, and came to the conclusion that she was pregnant. Remembering the fact that on my first examination the fundus uteri could be distinctly made out, and recognising the change which had taken place in the cervix, I further concluded that the pregnancy was Fallopian, and I communicated to this effect with Mr. Tapson, who visited her with me in the hospital. The sound was passed and entered over four inches, running up on the left side of the mass, where its point could be distinctly felt. The tumour now extended as high as the umbilicus, and lay almost wholly *on the right of the median line*. She was seen and examined by several of my colleagues, the majority of whom agreed with me as to the existence of pregnancy. The pain continuing as severe as ever, and no signs of uterine disturbance having resulted from the use of the sound, it was determined, with the concurrence of Mr. Tapson and my colleagues, that abdominal section should be performed to avoid the risk of rupture, which appeared very probable from the severity of the pain. The case was thoroughly explained to the patient and her husband, and by the former the risk was most cheerfully accepted as affording the prospect of relief from her well-nigh intolerable sufferings. I must state that, had I been guided solely by the results of this examination and had not seen the case at an earlier period, I should have looked upon the case as a uterine pregnancy of which the pain could not be explained. After a lapse of eight clear days from the passing of the sound, the patient was submitted to operation. On opening the abdomen it was at once apparent that, after all, the fœtus was in the uterus. On the left side the ovary was in its normal position, and there was a considerable space between the uterus and the side of the pelvis. On the right side the ovary was low down behind the tumour, which was in close contact with that side of the pelvis; in fact, the ovary had not risen out of its usual position in the unimpregnated state. Very little of the tube beyond the fimbriæ could be made out. It is almost needless to state that I at once closed the abdomen. The temperature on the following day rose from 99° to 100·2° (for four hours), and by the next day was quite normal. On the seventh day uterine action set in, and a fœtus weighing 1 lb., with a placenta 6½ oz., was expelled in a few hours. The patient had an uninterrupted convalescence, got quite rid of the pain, and returned home on Feb. 16th, much gratified with the result. Some there are, probably, who will say this was a simple uterine pregnancy. I think a careful study of the history will not support that contention. There can be no doubt that the uterine cavity did not contain the fœtus in the first instance, for both Mr. Tapson and myself were agreed that the body of the uterus could be distinctly defined at our first examination. The conclusion I have come to is that the ovum was arrested in the uterine extremity of the tube, and gradually worked its way into the uterine cavity. This view is supported by a case reported in THE LANCET of Jan. 16th, 1886, by Dr. Alexander Hay, and by another brought before the Obstetrical Society of London in October, 1885, by Dr. Grün, in both of which the physical signs very much resembled my case in its early stage. On submitting this report to Mr. Tapson, he replied, under date Dec. 10th: "I have nothing to add except that I saw her (Mrs. R.) about a week since, and she is in better health than she has been for years."

The sixth case was that of a single lady aged twenty-three, who till within a year had enjoyed good health. On dividing the peritoneum, which was very much thickened, a small quantity of a clear amber-coloured fluid escaped, and a very thin and delicate membrane presented, within which was contained a whitish flocculent fluid to the amount of two pints. No intestine was seen, but on removing as much as possible of this membrane the exposed surface presented a glistening and injected appearance. The cavity appeared to be limited by adhesion to the parietes. It was washed out with warm water, and the wound completely closed. The disease appeared to be of a tubercular nature. On the evening before operation the temperature was 100·6°, and it rose to the same height on the same evening, but for the next two days was nearly normal; it then began to rise in the evening for about ten days. At the end of three weeks she was out of bed, and when about to return home she complained of hypogastric pain, and on the twenty-third day a small quantity of fluid, similar to that removed at the operation, escaped. The temperature then became normal, and she returned home on the thirty-first day with a small sinus. This had not closed when I last heard of the patient, at the end of November, though she was then in very good health.

The seventh and last case was that of a married sterile

Digitized by Google

woman, aged fifty-one, whose case had been a puzzle to more than one, at one time presenting the signs of a cyst and at another those of ascites. As the latter had become predominant, and no definite explanation could be offered of this condition, I decided to explore rather than tap the patient. I operated on her on Nov. 10th last, removing ten pints of free fluid. There was no disease of the pelvis or abdomen to account for the fluid. The body of the uterus appeared to have completely atrophied, and what should have been the body of that organ formed the floor of the pelvis. No ovary could be found. At the splenic flexure the colon adhered to the parietes. The temperature remained normal, and when the patient left the hospital on the nineteenth day there was no reaccumulation of fluid.

Incomplete operation.—A married sterile lady, aged forty-five, consulted me on Sept. 16th, 1885, complaining of a dragging pain in the pelvis, a severe pain in the region of the bladder, frequent micturition, and sometimes retention of urine. On examination, an elastic mass filled the pelvis, bulging down into the vagina, and pressing the uterus upwards and forwards, close up behind the pubic symphysis. The cervix was almost obliterated; the uterine cavity measured two inches and a half, and was directed to the left side. I recommended operation, though I could not urge it, and the patient preferred to wait for two or three months. She returned at the end of December with all her symptoms much aggravated, especially the bladder trouble; and having made up her mind for active treatment, I operated on Dec. 26th. The pelvic tumour was then distinctly fluctuating. On opening the abdomen, the first thing that presented itself was the right Fallopian tube close to the cornu of the uterus, forming a mass as large as a hen's egg, and having a knuckle of intestine very intimately attached to it. On separating these, the muscular coat of the intestine was laid bare, and the edges of the peritoneum were brought together by several points of continuous suture. In the course of the separation the tube was opened into and seen to contain papilloma. External and posterior to this was a cyst with thin walls, which was aspirated, and yielded about half a pint of a thin fluid like weak tea. An attempt was now made to separate the collapsed cyst, and in doing this another cyst, deeper in the pelvis, was opened, with the escape of a similar fluid. I was, however, obliged to desist from the attempts at separation, and had to be content with freely laying open the cysts and removing a portion of cyst wall together with the papillomatous portion of the tube. I then washed out the cavity with warm water, put in a drainage-tube, and closed the wound. The patient went on very well for forty-eight hours, then the urine became scanty, the pulse rapid, the temperature rose to 102°, and the mind was obscured. With the decreasing urinary secretion, which ultimately ceased, the pulse increased in rapidity, with a falling temperature, the patient became comatose, and died towards the third day. No post-mortem examination was obtained. This case, I think, illustrates the danger of delay when there are symptoms of urinary pressure and obstruction. I have already spoken of the papilloma, and it is scarcely necessary to point out the necessarily fatal character of the disease, which must in a very short time have opened into the intestine.

This case, then, constitutes the last of the consecutive series of one hundred cases of abdominal section—consecutive not in point of date, but according to the table. All of them were performed between Feb. 13th, 1885, and Nov. 17th, 1886, inclusive, and without any of the so-called antiseptic precautions; some of the hospital cases were done whilst patients were dying of septicæmia in neighbouring wards, and I did not adopt the precaution of hanging up a wet carbolised sheet over the door. But the greatest care was taken to ensure cleanliness, which I described some years ago as "the most efficient of all antiseptic systems and the only perfect one." That, I think, is borne out by the results. It would be foreign to my purpose to institute any comparison with the results of other operators. The above narrative of one hundred consecutive cases is a statement of facts at the service of those who have a mind to exercise their ingenuity in the manipulation of statistics.

Granville-place, Portman-square, W.

AT a well-attended meeting of the governors and friends of the Charing-cross Hospital on the 9th inst., a committee was appointed to organise a special appeal on behalf of the funds of the institution.

CASE OF

GOITRE, FOLLOWED BY ASPHYXIA; TRACHEOTOMY; DEATH.

BY J. B. HURRY, M.A., M.D.

EMILY B——, aged thirteen, when first seen, was suffering from a goitre of very moderate dimensions, which had been growing for a year. No history of goitre in the family. The first symptoms appeared about Nov. 3rd, 1886, when the girl began to complain of dyspnœa, stating that it obliged her to rise early in the morning. This continued till Nov. 7th, when Mr. Christian of Reading (to whom I am indebted for permission to use these notes) was sent for, who saw the girl at 12 noon, and found her with some, but not urgent, dyspnœa; the breathing was noisy, but not stridulous; no signs of inflammation or feverishness; she ate well that day. At 11.30 P.M. the same day, Mr. Christian was again sent for, and on arrival found the girl in a state of extreme dyspnœa, and only partly conscious. He immediately came for me to assist him, and we both returned as quickly as possible, provided with the means of performing tracheotomy. On reaching the girl's house at 12.30 A.M. on Nov. 8th, all the signs and symptoms of asphyxia were present: the face was pale; conjunctival reflex almost abolished; complete unconsciousness; breathing excessively laboured. Mr. Christian proceeded at once to open the trachea between the cricoid and the enlarged isthmus of the thyroid gland. No anæsthetic was necessary, owing to the state of unconsciousness. On making the superficial incision, much venous hæmorrhage occurred; as soon as this had for the most part ceased, and the girl evidently being at point of suffocation, the trachea was incised, and a small silver tube rapidly introduced. Air passed in and out through it, but not freely, and a moderate amount of blood came with it at first. A larger tube was therefore substituted, but even then the breathing appeared very obstructed. The tube was kept clear by a feather, but the breathing was far from satisfactory; indeed, the asphyxia became more and more complete, till at about 2 A.M. on Nov. 9th (i.e. about half an hour after tracheotomy) death occurred.

I made the post-mortem examination on the same day, at 6 P.M., by removing the larynx, œsophagus, and the entire thyroid growth. On dissecting the mass, and opening the larynx and trachea from behind, nothing abnormal was found, except a moderately large goitre and a bilaterally compressed trachea. The incision made by the tracheotomy began immediately below the cricoid, and measured about two-thirds of an inch in length, two rings being cut through. A short distance below the incision, the trachea was considerably flattened from side to side for the distance of an inch; both walls were affected, but the left one most; instead of being convex outwards, it was slightly so inwards. There was no softening or kinking of the trachea. On introducing the tracheotomy tube as it would have lain during life, the lower end was found to reach nearly to the lower portion of the region of flattening. The tumour itself was nearly symmetrical on the two sides. The isthmus was continuous with the right lobe, but separated from the left by a groove; it measured one inch from above downwards and also from before backwards, and began immediately below the lower end of the incision. Each lobe was about as large as two hen's eggs; together they entirely encircled the trachea, and behind it came into contact for about the surface of one inch in an antero-posterior direction, and two inches from above downwards; they separated the œsophagus from the trachea. On making incisions into the thyroid, the tissues were uniformly firm; there were no cysts visible to the naked eye, nor any softened portions. On bringing the two lobes into the position they occupied during life, the lumen of the trachea was seen to be reduced to a narrow antero-posterior slit (the *Säbelscheide* of the Germans). The relation of the recurrent laryngeals to the growth was unhappily not noted.

Remarks.—This is one of the few recorded instances of sudden death from goitre, and the interesting question arises, What is the cause of death? No perfectly satisfactory answer has been given, especially in regard to the cases where (as in the above) there is no evidence of sudden increase in size. The view generally adopted is, I believe,

Digitized by Google

that the enlarged thyroid mass presses on the recurrent laryngeal nerves, and thus leads to closure of the glottis, and it has been proved experimentally that when these nerves (which supply both dilators and constrictors) are stimulated, the constricting muscles overpower the dilators and close the glottis. This view, however, hardly explains why a condition of very slight dyspnœa sometimes becomes suddenly intensified, and may lead to sudden death (in a case published by Seitz of Zürich death occurred in two minutes after the commencement of the severe dyspnœa). Another explanation occurred to me, while dissecting the muscles from off the growth, especially the sterno-hyoids and thyroids, which pass over the thyroid gland, and were found well developed in the above case. Suppose for a moment that the gradual enlargement of the growth causes some dyspnœa by pressure on the trachea or recurrent laryngeals. This will produce no special trouble, till suddenly one day, perhaps after an unusual muscular effort, the dyspnœa is sufficient to call the sterno-hyoid and thyroid (and possibly mastoid) into action, in their capacity of supplementary inspiratory muscles. These muscles, when contracted, will press the lateral masses of the gland down upon the trachea (which in this instance was already greatly narrowed), and thus increase the dyspnœa; this dyspnœa must, again, throw the muscles into greater activity, and thus a "vicious circle" might be set up, one factor increasing the other, and rapidly leading to a fatal issue. The same sequence of events may possibly occur where the muscles above mentioned and the recurrent laryngeals are the efficient agents, and where therefore death is due to closure of the glottis.

ST. GEORGE'S HOSPITAL.

A CASE OF CEREBRO-SPINAL MENINGITIS; RECOVERY; REMARKS.

(Under the care of Dr. EWART.)

THIS case is of some interest, as being a sporadic case of cerebro-spinal meningitis, which recovered, but retained the permanent sequelæ left in cases of the epidemic form. For the notes we are indebted to Dr. Griffiths, medical registrar.

W. T——, a carpenter, twenty-nine years of age, admitted Sept. 17th, 1886, had a family history of good health, and had always been himself strong and well. He worked in a carpenter's shop, under, so far as could be ascertained, good sanitary conditions. He had had no injury or blow, nor did he remember to have "taken cold." He first felt dull and heavy on Sept. 10th, and next day had rigors with much frontal pain, and some pain about the nuchal region; no vomiting, but there was obstinate constipation. On the 12th both eyes were inflamed, the inflammation increasing rapidly. On the 14th he lost the sight of the right eye, and on the 15th that of the left. Delirium set in on the 13th, with high temperature.

He was admitted on the seventh day of the illness, and presented a condition of much prostration, with subsultus tendinum occasionally. He had a coated tongue; the pulse was 88, the temperature 102°, and the respiration 24. He had much difficulty in bending the neck, and had some retraction of the head. He presented much chemosis, with turbidity of the cornea, and tension in both eyes was −2. His heart showed slight hypertrophy, with a general soft systolic murmur. There were no adventitious sounds over the lungs, and no enlargement of the abdominal viscera. His urine was high-coloured, sp. gr. 1024, but non-albuminous; and he was passing loose green stools in bed, having been given a purgative before admission. His deep reflexes were about normal; tache cérébrale well marked; an apparently normal abdomen.

The man remained in an apathetic state for three days, when he began to mend. His temperature was irregular—the maximum 103°; his pulse-rate averaged 108, and was quite regular. At no time had he any vomiting, and only slight pain in the neck, the chief seat of pain being in the frontal and occipital regions. His eyes showed gradually less chemosis, but the pupils dilated irregularly under atropine, points of lymph being seen on the anterior surface of the lens; the media, however, continued to be thick, though the cornea regained to a great extent their transparency. On Sept. 21st he had slight improvement in vision, and the media seemed slightly less thick, but he could only distinguish between light and shade, and by degrees this power diminished until he became absolutely blind. His general condition began to improve on the ninth day after admission, his temperature being then normal, and remaining at that level; and though he suffered from frontal headache, he continued to improve until discharged. He was then in fair health, but was completely blind, the media being quite thick and precluding ophthalmoscopic examination. He was treated during the acute stage with an ice-bag applied to the head and neck. He was given two drachms of solution of perchloride of mercury and ten grains of iodide of potassium every four hours, while a strong solution of atropine was applied to the eyes, at first frequently, but only twice daily after the second day. Six ounces of brandy were given daily at first. Later on aconite and belladonna liniment was painted over the forehead to relieve pain, and he was put on tonic treatment till his discharge.

This patient presented all the points of a case of cerebro-spinal meningitis, though many not of a marked character. His condition on admission was more that of prostration than of actual collapse, but the rapidity of onset, want of exciting cause, retraction of head, and progressive ocular symptoms all confirmed the original diagnosis. Among the many interesting papers written on the subject, we would especially refer to Dr. Wilson's paper in the *Dublin Quarterly Journal* for May, 1867, in which, though speaking of the epidemic form of this disease, he describes the ocular symptoms from conjunctivitis through suppurative choroiditis to amaurosis, either from collapse of the globe, detachment of retina, or actual atrophy of the same.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, CITY ROAD.

CASE OF EMPYEMA; FREE INCISION AND DRAINAGE AT LOWEST POINT; RAPID RECOVERY.

(Under the care of Dr. OSWALD BROWNE.)

FOR the notes of this case we are indebted to Mr. Harold Simmons, house-physician.

C. G——, a well-nourished girl, aged eight, was admitted from the out-patient department on Sept. 8th, 1886, giving a history of four months' illness, commencing, after unusual exposure, with rigor and cough, and marked by gradually increasing shortness of breath, pain in the left side, emaciation, and weakness. She had had no previous illness, nor was there any history of hereditary tubercular tendency.

Condition on admission.—Her face was pale and somewhat livid; lips bluish; respiration hurried and shallow, 40; pulse small and soft, 128; temperature 102°; skin moist. Thorax: The left side scarcely moved with respiration, the intercostal furrows were obliterated, and there was bulging of the upper walls of the chest; the percussion note was absolutely dull all over the side, and the respiratory murmur absent, except some distant tubular breathing audible at the extreme apex above the second rib, and some faint sounds along the spine at the inner border of the scapula. No tactile vocal fremitus was perceptible, and the voice sounds, feebly heard at the apex, were totally inaudible below. The right side was resonant; respiration loudly heard, and accompanied posteriorly by sonorous rhonchi. The heart's impulse could be felt in the right nipple line, one inch below the nipple, and the cardiac dulness extended thus far and joined the general dulness on the left side, its upper limit being the third cartilage; the heart sounds were loud and clear. The liver margin was an inch below the costal border in the right nipple line; the spleen not perceptible. Urine acid, containing no albumen.

Sept. 10th.—She was considerably more distressed and cyanosed, temperature had continued at 102°, and there had

Digitized by Google

been abundant expectoration of thick purulent sputa. An exploratory puncture of the left side procured thick pus.

Operation.—Chloroform having been administered, a short incision was made into the chest in the fourth intercostal space in the anterior axillary line, and through this a shortly curved rigid urethral sound passed as far as possible down and somewhat backwards, its point being projected in the ninth space in the line of the angle of the scapula, and on it a second incision made; on digital examination the finger entered the pleural cavity, a mass of soft adhesions being perceptible immediately in front of the incision; a large quantity of pus escaped freely. A drainage-tube about three-eighths of an inch in diameter and six inches long having been inserted in the lower opening, the upper wound was closed by sutures; there was little hæmorrhage. The side was dressed with carbolic gauze, the spray having been used throughout. The child had been extremely faint during the later stages of the operation, but revived quickly. The dressing was changed the same evening, the discharge being thin, blood-stained, and profuse; the patient in little pain, warm, and comfortable. Temperature 100·8°.

Sept. 12th.—Re-dressed; the dressing contained about four ounces of blood-stained pus, free from odour; the tube clear. The heart's apex was to the left of the sternum. Temperature, morning, 98°; evening, 99·8°. Expectoration of yellow sputa still continued.

13th.—The upper incision had almost healed; stitches removed and tube shortened. Temperature 99·2°.

15th.—Discharge less. The whole of the side was fairly resonant; over the upper half respiration could be well heard, but harsh and accompanied by coarse friction; at the base the breathing was audible, but distant; the heart's impulse was close to the left nipple line, the dulness reaching to the mid-sternum to the right.

16th.—Cough slight, and expectoration much less. Bowels had been extremely constipated. One-tenth of albumen was found in the urine. A mixture containing sulphate and carbonate of magnesia was ordered every morning.

17th.—She had passed a large quantity of uric acid in big crystals. Ordered eight grains of bicarbonate of potash three times daily.

20th.—The discharge had lessened much, and the general condition had much improved. The tube was again shortened. A trace of albumen still existed in the urine.

22nd.—The side had fallen in considerably; there was fair resonance all over and free air entrance in the upper two-thirds; the apex beat in the fifth space, one inch outside the nipple line. Bowels still very costive. Five minims of liquid extract of cascara sagrada ordered.

25th.—Discharge very scanty. The tube left out.

27th.—The spray was discontinued. Wound superficial and healing rapidly. There was no evidence of re-collection.

Oct. 5th.—Granulations pale and œdematous; a probe would not pass. She had no cough or expectoration, and felt quite well.

On the 21st the wound had quite healed, and on the 28th the patient left the hospital. The left side, sunken considerably, especially over the apex in front, yielded a resonant note of good quality; respiration was heard well all over, and free from adventitious sounds, except some coarse crackling with inspiration at the extreme base. Her temperature never rose higher than 99·2° after Sept. 13th, and albuminuria ceased on the 25th. She continued to pass uric acid occasionally.

Jan. 10th, 1887.—The child attended at the out-patient department. She had gained strength, weight, and colour. The affected side was more flattened anteriorly and posteriorly; breathing was loud and clear to the extreme base.

SEAMEN'S HOSPITAL, GREENWICH.

SURGICAL CASES OF INTEREST, WITH REMARKS.

(Under the care of Mr. G. R. TURNER.)

CASE 1.—*Sequel to a successful case of Fractured Patella treated by Wiring.*—William W——, aged twenty-five, a sailor, fractured his right patella whilst at sea. He had no treatment for twelve days, and was then in a foreign hospital for a month. The fracture was treated by strapping and a plaster-of-Paris splint. He left the hospital in a month's time, and then came under the care of Mr. Mayo Robson of Leeds, in June, 1885, four months after the accident. He had an ununited fracture of the patella, with an inch and a half's separation of the fragments. His limb was very weak, and perfectly useless to him. Mr. Robson cut down on the fragments and wired them together. Great difficulty was experienced in approximating them, the lateral expansion of the vasti and the quadriceps requiring division. The wound ran an aseptic course, and he was made an out-patient in September. He could walk freely, could flex his knee nearly to a right angle, but complained of a little pain below and to the outer side of the patella. A note says: "This may be due to some of the gold wire sutures which were not removed." On leaving Leeds he went to sea, and whilst on board ship fell and hurt his knee again, and was taken to a hospital at Sulina and treated. After this he came to the Seamen's Hospital, Greenwich. He had almost perfect use of his knee, and the patella appeared soundly united. Protruding from a sinus on the outer side of the joint was a wire, which he said had been catching his trousers as he walked since his last accident. There was a little suppuration around. On April 1st he complained of considerable pain in the knee-joint, which became rapidly distended with fluid. His temperature rose to 104°; pulse 128. The face and body were covered with an erythematous rash. On seeing him the next day, Mr. Turner, with full antiseptic precautions, laid the joint freely open on each side of the patella and introduced a drainage-tube. The fluid that escaped consisted of turbid lymph, hardly to be called purulent. The distension of the joint was very great before the operation. The projecting wire was removed; it could be traced in the cavity of the joint to just below the patella, and was there lost. The man's temperature and pulse rapidly fell nearly to normal after the operation, and the wound ran an aseptic course. His convalescence was interrupted now and then by epileptic fits, to which he was subject. Two other wires became prominent under the skin, and one projected through it. These were dissected out on the 4th of July, and he shortly afterwards was up and about. After he was discharged he again fell down (? in an epileptic fit), and refractured the same patella very close to the insertion of the ligamentum patellæ. This fresh accident brought to light yet another wire, which was removed in September, and the man shortly afterwards left the hospital. He could walk perfectly, and could bend his knee to more than a right angle. He could not, however, perfectly extend it, as there was some slight wasting of the quadriceps—not sufficient, however, to interfere in any way with his activity. It should have been mentioned that his second fracture was treated simply by rest and strapping, the lower fragment being obviously too small for wiring, even had such a proceeding been contemplated.

Remarks by Mr. TURNER.—This case (the notes of which were kindly sent to me by Mr. Mayo Robson) is of interest, I think, as showing how troublesome, and even worse, wires may become if the knee which contains them is subjected, as in this instance, to renewed injury. The man's frequent accidents were no doubt due to his epileptic tendency. His present condition is, on the whole, satisfactory. At one time he was very near having acute suppuration of the knee-joint. Timely incision into the tense distended joint at once reduced his temperature from 104° to 100°, and materially improved his general condition. The wires were troublesome to remove, and were not finally got rid of for some considerable time. Mr. Mayo Robson used but three gold wires to suture the patella. I must have had to deal with two fragments of one of these. The strength of the osseous union obtained by their means is shown by the second fracture occurring below instead of at the seat of the first.

CASE 2. *Compound Comminuted Fracture of the Ulna into the Elbow-joint; recovery with a movable joint.*—Wm. C——, aged thirty, presented himself at the hospital with a wound leading down to a comminuted fracture of the ulna at the junction of the olecranon and coronoid processes due to direct violence. Two loose fragments of bone were removed by enlarging the wound, and the parts and joint were washed out with carbolic lotion. The wound ran an aseptic course, and healed shortly after a drainage-tube that had been introduced into the joint on his admission was removed. Passive motion was then daily employed. Shortly after commencing this a peri-articular abscess formed, and was opened. A second abscess appeared later on, and was likewise opened. As soon as it was possible passive motion was again practised, and the patient encouraged to use his elbow. He remained in hospital doing

Digitized by Google

work about the place for three months or so. He suffered from pain referred to the distribution of the ulnar nerve. He was of a very sensitive nature, or there is no doubt his progress would have been more rapid. When last seen the relations of the olecranon to the condyles of the humerus were normal. An inch below this process is an irregular transverse depression indicating the seat of fracture. There is a depressed cicatrix at the site of the old wound, and the bone beneath is somewhat irregular. He can flex the elbow so as to touch his shoulder with the tips of his fingers, and extend it to an angle of 150°. The radius can be rotated, and both flexion and extension are "getting better every day." The joint is very strong; he "can carry four gallons easily," or "with another man can lower thirty gallons of rum." All the symptoms referable to the ulnar nerve have disappeared.

Remarks.—This result to a compound comminuted fracture into the elbow-joint is a very satisfactory one, and better than if a formal excision of the articulation had been practised.

CASE 3. *Dislocation of the Foot backwards.*—Henry H—— aged sixty, was knocked down in a scuffle, and fell with his right foot under him. On admission, the dorsum of his right foot was considerably shortened and the heel correspondingly lengthened. The foot was at right angles to the leg, and the lower end of the tibia very prominent; the fingers could almost be placed under the anterior edge. The internal malleolus was fractured and carried backwards with the astragalus. Reduction was easily effected by extension and then carrying the foot forwards. The position was then good. The man recovered, with some increased width between the malleoli.

The interest of this case rests solely on the rarity of backward dislocations of the foot.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Fibroma of Ovarian Ligament.—Metastatic Carcinoma of Prostate.—Large Dermoid Cyst over Sternum.—Gall-stone causing Obstruction of Bowel.—Cystic Disease of Testicle.—Multilocular Cystic Epithelioma of Jaw.—Cystic Epithelioma of Neck.

AN ordinary meeting of this Society was held on Tuesday last, Sir James Paget, F.R.S., President, in the chair.

Mr. SHATTOCK read for himself and Mr. R. W. Parker the report of the Morbid Growths Committee on Mr. Butlin's case of Recurrent Tumour of the Breast. It had a foliaceous aspect, like some cases of adeno-sarcoma of the breast, but the histological characters of the growth were those of villous carcinoma originating from the ducts, as distinguished from the acini.

Mr. ALBAN DORAN showed a small Spherical Tumour in the Substance of the Left Ovarian Ligament. A microscopic section was also shown. It proved that the tumour was made up of plain muscular fibres, mingled with white fibrous tissue; in fact, it was a "fibroid" precisely similar to several other fibroid growths which, in this case, were found in the uterus. The ovarian ligament was a prolongation of uterine tissue, its fibres passing into the parenchyma of the ovary. Hence it was subject to fibro-myoma, like the uterus, whence it was derived; and hence, also, fibro-myoma was sometimes developed in the ovary into which it ran. It was probable that fibro-myoma of the ovarian ligament had been sometimes mistaken for a so-called supernumerary ovary. In this case the latter condition existed on the right side.—Mr. SHATTOCK said that he often had a difficulty in differentiating fibrous tissue from plain muscular tissue in examining ovarian tumours.—Mr. ALBAN DORAN, in reply, said that he sympathised with Mr. Shattock's difficulty, but thought that well-marked nuclei such as might be seen in plain muscular tissue in the uterus of the new-born was diagnostic, and these were also to be found in incipient myoma of the ovary.

Mr. HURRY FENWICK showed a specimen of Metastatic or Secondary Carcinomatous Deposit in the Prostate. He could only find four examples of this class of carcinoma of the gland in medical literature (Mercier, Langstaff, Guyot, and Lebert). In three of these cases the primary growth was found in the stomach; and in the last the dura mater was the site of the initial deposit. The specimen was removed from a man aged twenty-six, whose first symptom was great lumbar pain. The duration of the entire illness was two months and a half. The spinal cord finally became attacked, and paraplegia ensued. The necropsy revealed the lung to be primarily affected, and the liver, spleen, kidneys, prostate, and cord secondarily. The growth was of the "scirrhoid" type.

Mr. H. H. CLUTTON showed a large dermoid cyst removed from over the sternum in October, 1886. The subject of it was a married woman aged thirty-nine. The tumour was noticed at the age of six weeks to be of the size of a pea. At ten years it was tapped, but no fluid withdrawn. At nineteen it was of the size of a hen's egg. It remained stationary for many years, but during the last five years it had grown to twice the size. The tumour hung in a pendulous fashion from the sternum on a level with the breasts, and measured thirteen inches in circumference. The entire cyst was removed. Its lining membrane appeared to be of cutaneous structure, and one hair could be seen projecting from its surface. Microscopically, neither sebaceous glands nor hair follicles could be found. The contents, which measured eleven ounces, were composed of epidermis, cholesterine, and fat.—Mr. F. S. EVE had examined several dermoid cysts which did not contain sebaceous glands or hairs. Dermoid cysts occurred in various situations, as over the scapula, where they were in no relation with the branchial clefts or with the middle line of closure. They originated from displacement of epiblast.—Dr. ANGEL MONEY referred to a case (recorded in the *Journal de Médecine de Bourdeaux*) of apparent dermoid cyst communicating with the central canal of the spinal cord at the level of the lower end of the cervical enlargement.—Mr. STEPHEN PAGET said that in hairy chests there was regular parting of the hair at the angulus Ludovici, the hair above growing upwards and below growing downwards.—Mr. J. HUTCHINSON, jun., said that he had met with three cases of dermoid fistula in the middle line at the junction of the nose and forehead.—Mr. BLAND SUTTON said that the situations mentioned by Mr. Hutchinson was a common site for meningoceles.—Mr. HUTCHINSON, jun., said the cases he referred to were undoubtedly dermoid cysts, and not meningoceles.—Sir JAMES PAGET had removed three such growths, and in none was there any connexion with the interior of the skull; but in one case a pedicle extended between the nasal bones. They were undoubtedly dermoid. One case was also associated with a spina bifida. There was sometimes an unusual growth of the dermoid cyst at the time of puberty, when there was a greater activity of the organs derived from epiblast.—Mr. A. A. BOWLBY had observed two undoubted dermoid cysts in the area of junction between the nose and forehead.—Mr. CLUTTON said there was no evidence of increased growth until the patient got married. He had removed two dermoid cysts from the forehead at the root of the nose. Such cysts occurred in any part of the body, though most commonly in the middle line or along the lateral fissure.

Dr. PYE-SMITH showed a large Gall-stone removed from a lady aged seventy-eight, who had never had jaundice, but suffered from increasing constipation, which culminated in obstruction. Examination per rectum revealed something abnormal, which was regarded as possibly carcinomatous and situated above the sigmoid flexure. It was very movable. After thirteen days' obstruction the stone was passed and the patient remained free from trouble. A second larger stone of cylindical shape was also shown. It came from a woman aged sixty, in whom constipation never proceeded to complete obstruction. The date at which the communication between the duodenum and gall-bladder occurred was unknown.—Mr. J. HAMMERSLEY said that the patient in the first case remained perfectly well.—Mr. SHATTOCK mentioned a fatal case of complete obstruction from gall-stone. It was an unpublished case of Dr. Bristowe.—Dr. COUPLAND thought it unlikely that any subsequent difficulty would occur, for the opening into the duodenum from the gall-bladder must be large to have allowed the safe passage of a stone of that magnitude.

Mr. EVE read a paper on Cystic Disease of the Testicle. It was based on a microscopic examination of twelve selected specimens, and a table of twenty-eight recorded cases in which a microscopic examination had been made. There

Digitized by Google

were three forms—cystic fibroma, cystic myxoma, and sarcoma, the second being intermediate between the other two. In the cystic fibromata the cysts and tubules were commonly lined with spheroidal or flattened epithelium, but some, in most tumours, with columnar, and in five specimens with columnar ciliated epithelium. Unstriped muscle was rarely, and cartilage generally, present in the fibrous stroma. Cystic myxomata were composed of mucous and fibrous connective tissue, containing tubules of columnar, ciliated, and occasionally flattened epithelium—very like the same tumours in the breast. In cystic sarcoma the cysts were a less prominent feature, and more commonly lined with columnar than flattened epithelium. The characteristic components of cystic fibromata—viz., ciliated epithelium, unstriped muscle, and cartilage—were present in sarcomata, and in three cases striped muscle was found. After reviewing the evidence regarding the origin of tumours, the following conclusions were stated:—1. No specific difference exists between innocent and malignant cystic tumours. 2. They originate in the hilum testis. 3. There is probably a new formation of epithelium, or adenomatous growth. 4. The prototype of this is found in the tubules of the vasa efferentia, rete testis, and coni vasculosi, which are formed from the Wolffian body. 5. There are grounds for believing that the epithelial formations in cystic tumours originate from certain outgrowths from the Wolffian body described by Klein as interstitial cells, and normally occupying the hilum. 6. It is incorrect to attribute their origin to the organ of Giraldès, as this lies outside the testicle.—Mr. C. B. LOCKWOOD said that a perfect series of complete transverse sections through the organ would be the best way of determining the relations of any relics of the Wolffian bodies.

Mr. A. A. BOWLBY exhibited a specimen of Multilocular Cystic Epithelioma of the Jaw. The patient was a woman aged twenty-four, in whose lower jaw on the left side the tumour began to grow at the site of a decayed molar tooth. It was removed by Mr. Walsham, but one year later it began to recur. It had grown both outwards into the masseter muscle and inwards into the mouth, which could not be shut. The duration of the case was twelve years and a half. The cysts contained a reddish-brown blood-stained fluid. Microscopically, the growth was composed of fibrous tissue, into which the processes of epithelium of cylindrical, spheroidal, and flattened sort grew. The cysts originated from the epithelial ingrowths. The specimen corresponded closely with those described by Mr. Eve.

Mr. QUARRY SILCOCK showed three cases of Cystic Epithelioma of the Neck. Case 1: A man aged thirty-two, was admitted into St. Mary's Hospital with a large inflamed suppurating swelling under the lower third of the left sterno-mastoid muscles; he had first noticed a small lump in that situation about three months earlier; it was painful, and the patient, who was a strong healthy man, began to lose flesh and strength. The swelling had been opened, and after admission Mr. Owen scraped away large portions of the growth, with temporary relief. After death, though no complete necropsy was allowed, it was ascertained that the growth occupied the posterior as well as the anterior triangle, and infiltrated all the structures. There was a large cystic cavity lined by large papillary granulations, which were found to consist almost entirely of epithelial cells, the most highly developed being of the squamous type, but not prickled, forming well-marked nests and long columns running downwards into the mass of the tumour. The enlargement of lymphatic glands lying over the growth was found to be due to inflammatory irritation only. Case 2: A man aged fifty-six was admitted with a large, partly cystic, tumour on the right of the neck, which had been growing for about five months. He was emaciated. The cyst was incised by Mr. Pepper, and a quantity of glairy yellow fluid escaped. The cyst, which was lined with papillary granulations, subsequently suppurated. Examination after death revealed the same macroscopical and microscopical appearances. Case 3: A man aged sixty-four, who was admitted with a large tumour on the left side of the neck lying in greater part beneath the sterno-mastoid muscle, but involving both triangles; it extended from the jaw to the clavicle, to the middle line in front, and to the mastoid process posteriorly. Mr. Silcock tapped the cyst several times, and drew off a thick, yellow, grumous fluid, which was found to contain numerous large epithelial cells, which left little doubt that the growth was of the same character as in the other two cases, from which he was able to show specimens. In none of the cases was there any evidence of a primary growth elsewhere. He thought the only hypothesis which could be entertained was that they owed their origin to the development of some belated portion of epiblast, perhaps the representative of a branchial cleft, although the advanced age of the individuals in whom they were usually found appeared to negative such a supposition.

The following card specimens were shown:—Mr. Godlee: Malignant Disease of an Undescended Testis with Secondary Growths. Mr. Stonham: Pelvis of a Child with Persistent Fœtal Condition of the Peritoneum. Mr. F. W. Clark: Subpleural Lipoma of Diaphragm. Dr. A. H. Robinson: Drawings of Charcot's Joint Disease. Dr. Ormerod: Subdural Hæmatoma. Dr. Maguire: Bullet Wound of Heart passing through the Left Ventricle.

CLINICAL SOCIETY OF LONDON.

Pneumothorax with Recovery in the apparently Healthy.—Intra-peritoneal Excision of Rectum.—Gymnastic Treatment of Scoliosis.

AN ordinary meeting of this Society was held on Friday, the 11th instant, Dr. W. H. Broadbent, President, in the chair.

Dr. DE HAVILLAND HALL communicated a case of Pneumothorax which he had had under observation, with notes of four other cases. Case 1: F. R. P——, aged twenty-four, was sent to Dr. de Havilland Hall by Dr. W. D. Penny on June 27th, 1885. The account given by Dr. Penny was that on May 8th the patient complained of sharp pain in the left side of the chest. In the mid-axillary line, low down, there was pleural friction with slight dulness on percussion and tubular breathing. The dulness only covered a very small area, and the rest of the chest was quite normal. Pulse 110; temperature 100·4°. The patient was sent home to bed, and next day there was hyper-resonance all over the chest and extending half an inch to the right of the sternum. Breathing replaced by amphoric roaring and loud tinkling, except that at the angle of the scapula the respiratory murmur was faintly audible. Heart sounds muffled, apex beat half an inch inside right nipple. Pulse 140; temperature 99°. The patient stated that while getting into bed he suddenly felt faint, and had a peculiar sensation about the heart. In the course of a month the symptoms slowly subsided, the heart returned to its natural position, and the breath sounds returned. A fortnight later there was a return of pain and shortness of breath. When examined by Dr. Hall the patient had just come from business. There was only slight complaint of pain, and there was not much dyspnœa. Pulse 120; heart sounds clear. Impulse in epigastrium. The left side of the chest hardly moved at all; there was general hyper-resonance and obliteration of the cardiac dulness. No breathing sounds were audible over the left side. The bell sound could not be elicited. The right lung was normal. The urine contained a trace of albumen. On Sept. 30th the patient was again examined, and both lungs were found perfectly free from disease. Case 2 (notes supplied by Mr. B. Rix, of Tunbridge Wells): J. W——, aged thirty-nine, mason's labourer, previously in good health, and in constant work for the past eleven years. While sweeping, he was seized with sudden pains just above the left nipple, and came over faint. He continued at work for five days, but owing to increasing dyspnœa and pain had to take to his bed on the fifth day. On examination, there were the physical signs of pneumothorax on the left side. He was under observation for seven weeks, during which time the heart gradually resumed its normal situation, the hyper-resonance disappeared, and normal breathing returned. Case 3 (recorded by Dr. Delagrange, *London Medical Record*, 1881, p. 196): A healthy youth, aged nineteen, while exhibiting the powers of his chest, suddenly felt severe pain in the left side; his face became blanched, and he experienced great oppression. During an effort to vomit he was seized with a sense of something tearing in his side, followed by syncope; there were unmistakable signs of pneumothorax. The patient recovered in about eight days. Case 4 (recorded by Biermer, *Würzburgher Med. Zeitschrift*, Bd. i., p. 385): K. D——, a law student, aged nineteen, while dancing, was seized with a peculiar sensation in the region of the heart, accompanied with giddiness, oppression, and sweating; when examined four days later, there were the physical signs of pneumothorax on the left side, accom-

Digitized by Google

panied by a moderate amount of liquid effusion. In seven weeks all objective signs of the pleural affection had disappeared. Case 5 (recorded by Ricker, *Wien. Med. Wochensch.*, March 28th, 1860): A badly developed young man of eighteen years of age, was seized, while coughing, with a stabbing pain in the left side. A week later he complained of considerable shortness of breath, and the physical signs were those of a pneumothorax. The distress increased so much that he was punctured, and the operation was followed by an alleviation of all his symptoms. Two months later, he presented a more healthy aspect than before his illness. After remarking on the comparative rarity of cases of pneumothorax occurring among the apparently healthy, Dr. Hall drew attention to the cases collected by Dr. Samuel West in a paper read before the Society in 1883, and to the cases reported to the Medical Society in March, 1886, by Dr. Whipham. Dr. Hall considered that the explanation of great preponderance of males over females in the subjects of this affection is to be found in the greater muscular exertion of males compared with females, and that, whatever might be the predisposing cause, the immediate cause of the pneumothorax is some strain. He had no doubt that in a majority of cases the rapid breaking down of a small tuberculous mass before a secondary pleurisy had had time to set up adhesions was by far the most frequent cause of pneumothorax. The paper concluded with some remarks on diagnosis and treatment.—Dr. S. WEST considered that Dr. Hall was right in styling his paper "Pneumothorax in the apparently Healthy," for the lungs were not perfectly normal. He referred to cases which originated in slight cases of phthisis. The pressure at which healthy lung would burst was very much greater than might be supposed. He was working at this subject experimentally. As to traumatic pneumothorax, he believed that its occurrence in association with fractured rib was rare, though surgical emphysema was common. He inquired as to the experience of surgeons in this matter.—Dr. BURNEY YEO thought that the title of the paper rather begged the question, for it assumed that patients were previously healthy. Dry pleurisy as a cause of this accident was not laid sufficient stress on by Dr. Hall. This form of pleurisy was frequently latent.—Dr. S. MACKENZIE related a case, seen with Mr. Drake of Stratford, that occurred in a graduate of a university who left the drawing-room after dinner to fetch a banjo; he was found seated on the stairs suffering severely. He had suffered some time previously from a "stitch in the side," which was probably due to pleurisy.—Dr. S. COUPLAND agreed that small patches of phthisical change and relics of small foci of tubercle of the lung were causes of this kind of pneumothorax. He had had under his care two cases of recovery. There was no evidence of phthisis in either of the patients, and their family history was good. They both followed a sedentary occupation. He did not think that much exertion was necessary to produce a rupture of the lung if there be a suppurating area. Coughing probably caused more violent strain on the lung than any muscular voluntary exertion. The first case was that of a clerk aged eighteen, whose right side was affected. In one month all the signs had disappeared. The second case occurred in a still more healthy-looking man, who five days before admission caught a cold, and three days later had pain in the side. When first seen the pneumothorax was well developed. At first no improvement resulted, but after leaving the hospital ten days all the signs had disappeared. The patients suffered very little from their affections after the first symptoms had subsided.—Mr. G. R. TURNER had not observed any cases of pneumothorax with fractured rib. He had seen a boy who had hæmoptysis, and who died from pneumothorax due to phthisis.—Dr. TYSON mentioned a case of emphysema due to pyæmia, the consequence of a sloughing ulcer of the leg in an elderly woman.—Mr. RIVINGTON had only met with two or three cases of pneumothorax of all the cases of thoracic injury he had seen during his long experience at the London Hospital.—Mr. HOWARD MARSH referred to a case of a boy who was run over and died with much dyspnœa and collapse. The lung was clean torn away from the bronchus on that side. He mentioned cases of ruptured lung from falls; in one a woman fell across the step of an omnibus, and the visceral pleura was found to be largely rent at the necropsy. He considered that pneumothorax was not unfrequent when the ribs were fractured.—Mr. B. PITTS had seen several cases of traumatic pneumothorax. In one case, that of a boy aged six years, aspiration gave much relief to the dyspnœa, but death ensued from inflammatory symptoms. Rupture of the lung, but no fracture of the ribs, was found at the necropsy.—Dr. WEST said that he had asked for information concerning the occurrence of pneumothorax with fractured rib.—Dr. BROADBENT had seen three cases of the kind. In one it occurred while the patient was taking a cold bath in the morning. All occurred in young men; two on the left side, and one on the right.—Dr. HALL, in reply to Dr. B. Yeo, said that perhaps the pleurisy was caused by the phthisis which also caused the pneumothorax.

Mr. FREDERIC S. EVE read a case of Intra-peritoneal Excision of the Rectum, with recovery. The patient, a woman aged thirty-four, had suffered from symptoms of cancer of the rectum for nine months. The growth encircled the rectum, and it was thought that the finger could be passed beneath its upper margin. The usual operation of excision was undertaken, but as the upper limit of the growth could not otherwise be reached, the peritoneal reflection encircling the bowel was divided, and the diseased portion removed with the écraseur. The bowel excised measured nearly six inches in length. The upper end was readily brought down to the anal margin. The patient is now, five months after operation, in good health. Good recovery, without symptoms of peritonitis. Remarks in recent researches on the experimental production of peritonitis tended to show that this operation should not theoretically be exceptionally dangerous, and that the limits of cases deemed fit for operation might be determined.—Mr. HARRISON CRIPPS considered that the title was a little misleading, for he had expected to hear that abdominal section had been performed. Speaking out of book, he should say that in one case in every five it was necessary to remove a portion of peritoneum in excision of cancer of the rectum. He said that he had not had a single fatal case of twenty-five operations, and in six of these the peritoneum was involved and excised. Immunity for two or three years often followed, when the lowest portion only of the rectum was affected; but if the disease extended higher up, six months was the average period of immunity.—Mr. GOLDING BIRD asked what power the patient had of holding the motion, to which Mr. EVE, in reply, said that there was no specific information on this point in the letter received from the patient. Mr. Eve was surprised to hear that the peritoneum was opened so frequently by Mr. Cripps, for in the latter's work only two cases were specially mentioned. The value of the method practised in the case read was to enable examination of the bowel to be made for a distance above the cancerous portion. He had left a considerable part of the external sphincter. In reply to Mr. C. Heath, he said that stitches were used to unite the bowel to the anus.

Mr. KEETLEY read a paper on Scoliosis, and said that, having received from Mr. Bernard Roth a paper on the results of the Gymnastic Treatment of Scoliosis, he asked that gentleman for permission to see the treatment. Mr. Roth consented, on condition that Mr. Keetley should send him a case (of the hospital class) for treatment. This condition being fulfilled, Mr. Roth (with Mr. Keetley's consent) exhibited the patient at the Clinical Society twice, once before and once after, a course of gymnastic treatment. (Mr. Roth's views of this case are stated—with illustrations—in the Clinical Society's Transactions.) Mr. Keetley, while acknowledging that the patient's spirits and muscular strength were improved by the gymnastics, states that she had lost in height, and that the scoliotic curves had undoubtedly increased during the treatment.—Mr. BERNARD ROTH said the patient had been sent to him by Mr. Keetley with a request to do what he could for her, and no intimation was given of an intention to read a paper until last Saturday; further, he had applied in vain to know what line of criticism Mr. Keetley intended to follow. He defended his history of the cases reported in the Transactions, and protested against Mr. Keetley's paper being published by the Society unless his answer was appended. The patient in question had suffered from lateral curvature for ten years, and had been under various treatments. In spite of plaster jacket &c., she had become frightfully deformed, and this had gradually got worse. He had told Mr. Keetley that he would do his best, and would make her independent of spinal supports in three months, though the osseous deformity would of course remain. He showed photographs and tracings of the ribs. The patient was shown at the Society in November, 1885, and again, after the three months' treatment, in March, 1886, and Mr. Keetley then made no objection. Both patients were pre-

Digitized by Google

sent, and had been examined by members. If his reply could not be appended, he would urge the appointment of a committee to report upon the cases, as well as on the case which he had shown in April, 1883.—Dr. BROADBENT thought that the best course would be to appoint a committee.—Mr. CHRISTOPHER HEATH said that the permission of the Council for the production of Mr. Keetley's paper at the Society would perhaps have been withheld if it had been known that the character of it was to be so entirely controversial. The Council gave permission for a paper on scoliosis generally. As the subject was of great importance to the profession at large, he thought that the appointment of a committee to inquire into the whole subject of scoliosis and its treatment would be a good step for the Society to take.—Mr. H. MARSH seconded Mr. Heath's motion, and thought that the pathology and treatment of lateral curvature was still in an undecided condition.—The committee was appointed, and consists of the following gentlemen:—Messrs. Christopher Heath, Howard Marsh, Walter Rivington, Warrington Haward, and R. W. Parker, the surgical hon. sec.

MEDICAL SOCIETY OF LONDON.

"Clottage" of the Ureters.—Certain Conditions of Bladder in Children.

AN ordinary meeting of this Society was held on Monday last, Dr. Hughlings Jackson, F.R.S., President, in the chair. The new Surgical Secretary, Mr. Bernard Pitts, took his seat at the presidential table, and Dr. Samuel West occupied the post of senior honorary secretary.

Dr. ORD proposed, and Mr. WM. ADAMS seconded, a cordial vote of thanks to Mr. Brudenell Carter for the admirable way in which he had fulfilled the duties of president during the past year. Mr. BRUCE CLARKE and Mr. MARMADUKE SHEILD did the honours of the vote of thanks to Mr. J. H. Morgan. Both votes were duly carried.

Mr. HURRY FENWICK submitted for criticism an operation which he termed "Clottage of the Ureters." The procedure consisted in an attempt on the part of the surgeon to "block" or "cork" up a ureter with blood clot. He argued from statistics that it ought to be performed in those cases where the surgeon has to combat profuse and uncontrollable hæmaturia from a kidney hopelessly crushed by an accident or affected with advanced carcinoma. He considered it a conservative operation, and one that ought to rank in front of the operation of nephrectomy. Mr. H. Fenwick's ureter aspirator[1] is introduced into the bladder. Suction is then practised on the ureter of the damaged kidney so that the blood clots are drawn into the eye of the instrument; light pressure is then made with the back of the instrument against the opposing finger in the rectum, thereby nipping the ureter lightly. Time is thus given for the blood clot to collect in the pelvis of the kidney. A case in which the operation was successfully performed was related. It was that of a man aged fifty-one with right renal carcinoma. The hæmaturia had lasted thirteen months; it had been intermittent and profuse. The urine remained free from blood from the time of the operation till his death six months later. No necropsy was made.—Dr. TUCHMANN thought it was impossible for the finger or any instrument in the rectum to nip the ureter. He handed round his own instrument for aspiration of the ureters.—Mr. HENRY MORRIS considered that Mr. Fenwick had introduced an ingenious thought. It would have been impossible, even had a necropsy been made, to have said whether the obstruction was due to the blood clotting naturally or to the result of the procedure practised by Mr. Fenwick. If hæmaturia from traumatism were not checked by ergot or hazel witch, the better treatment would be nephrectomy.—Mr. R. W. PARKER inquired whether the hæmaturia were due to the traumatism or to the malignant disease itself. He agreed with Mr. Morris that the *rationale* of this method was not clear. He questioned even whether actual clotting would stop the hæmorrhage.—Mr. BRUCE CLARKE said that it seemed to him that the best method of stanching the hæmorrhage was to cut down upon the kidney and to attack the bleeding vessel. He considered that it was almost impossible to be sure that the instrument would effect the desired object.—Mr. BERNARD PITTS agreed that the danger arose from intra-peritoneal hæmorrhage rather than from hæmaturia, in traumatic cases. In severe cases treated by rest, and without surgical interference, he had known casts of the ureters to be passed. The suggestion was made that the instrument might be used to clear out clots by aspiration, as for instance in attempting to cure some cases of hydronephrosis.

Mr. BRUCE CLARKE read a paper on Certain Conditions of the Bladder in Children. The roughened interior of the bladder was a far more frequent occurrence in children than adults, and the symptoms of stone were far more often present than a stone itself. Cases illustrative of these two facts were narrated. He believed that chilling of the surface of the body was an important causational element in these cases. The treatment of rest in bed, including universal warmth of the surface, with regulation of the diet and the administration of tonics, was mostly efficacious.—Mr. R. W. PARKER considered that text-books were often incorrect in the statement of the symptoms of stone in a child. He had known stone in girls to give rise only to tenesmus and dysenteric diarrhœa. Preputial irritation and tubercular disease of the bladder should be borne in mind in analysing the symptomatology of stones in the bladder.—Mr. MARMADUKE SHEILD had known malignant disease of the pelvis to be mistaken for stone. Retention of urine might be the only and first symptom of vesical stone in children.—Mr. HENRY MORRIS ventured to ask whether the condition described by Mr. Bruce Clarke might not be due to something very different from phosphates. In fact, in some cases he believed that the urine might have been over-acid in the first place. Might not errors of diet be a cause of the over-acid state of the urine, which led to the cystitis and alkaline urine?

[1] THE LANCET, Sept. 18th.

OPHTHALMOLOGICAL SOCIETY.

Ophthalmoplegia Externa.—Papillary Movement in Lateral Deviation.—Picture painted after Extraction of Cataract.—Fibroid Degeneration of Ciliary Muscle.—Paralysis of External Recti.—Associated Movements of Upper Lid and Eyeball.—New Formation in Vitreous.—Tubercular (?) Disease of Choroid: Extirpation of both Eyes.—Closure of Sclerotic Wounds by Conjunctival Sutures only.—Lateral Nystagmus.—Conjugate Palsy of Ocular Muscles and Nystagmus.

AN ordinary meeting of this Society was held on the 10th inst., Mr. J. Whitaker Hulke, F.R.S., President, in the chair.

The PRESIDENT announced that Mr. James Dixon, consulting surgeon to the Royal Ophthalmic Hospital, Moorfields, had presented a complete series of Von Graefe's *Archives*, from the beginning up to the year 1875.

Dr. C. E. BEEVOR showed a case of Ophthalmoplegia Externa without other symptoms. It was that of a woman aged forty, who had rheumatic fever six years ago, after which the right eye suddenly turned outwards, but it was doubtful whether the left eye was affected. The patient did not know that her eyes were fixed till told so. The up-and-down movements are weak, but there is almost complete paralysis of the lateral movements. There is a considerable degree of ptosis, probably due to the consensual movement of looking, which is very deficient. The pupils are equal, and react to light and accommodation; convergence is lost. The optic discs are normal. There was no history of syphilis, and no evidence of tabes, but some improvement has followed treatment with iodide of potassium.

Mr. MARCUS GUNN showed a case of Pupillary Movement in association with Lateral Deviation. The boy, aged ten, had a blow on the left eye with a cricket ball two years ago, which had left sight dim on that side. There is considerable lenticular opacity, and no fundus reflex; there is bare perception of light; projection is extremely defective, being accurate only outwards. On fixing a distant object with the right eye for some seconds, nystagmus commences in the left only, slight in degree, and lateral. On looking strongly to the left, both eyes exhibit nystagmic movements. On lateral deviation to the left both pupils contract, while they do not change on lateral deviation to the right, nor in association with any other muscular movement except convergences, when they act normally. Both pupils react well to light, but the left alone contracts feebly to exposure from the great defect of vision. The downward movement of the left eye is somewhat impaired, and on looking upwards the left is strongly divergent.

Mr. BRUDENELL CARTER showed a picture painted after recovery from Extraction of a Senile Cataract. The artist is about fifty-five, and was operated upon for mature senile cataract of the left eye in November. The right lens was at that time partially opaque, and became completely so by the end of 1885. It has not been operated upon, and the picture was painted in October, 1886, with the left eye only. The drawing of the lines about the upper part of the porch show the absence of astigmatism, the correcting lens being spherical only.

Mr. KAROP showed a case of (?) Fibroid Degeneration of the Ciliary Muscle.—Dr. BRAILEY was not satisfied that there was fibrous degeneration; it might be that the muscle had been displaced, stretched, and extended, but he said that there was an abnormal layer of nuclei; he did not say it was fibrous.

Mr. J. G. MACKINLAY showed a case of Paralysis of both External Recti, probably congenital. The patient was a girl, aged sixteen. There was no diplopia, nor has there ever been. No other muscles were affected. The pupils reacted well to light. Acuity of vision was greater in the left eye. There was astigmatism of both eyes. Partial deafness existed on both sides.

Dr. ERNEST CLARKE showed a case of New Formation of Vessels in the Vitreous Body.

Mr. BRUDENELL CARTER showed a case of Large Spontaneous Vitreous Hæmorrhage in a young man which had almost completely absorbed.

Mr. C. HIGGENS showed a case, in a boy aged seven, of Hæmorrhage in the Vitreous Body with a peculiar deposit behind the retina (? inflammatory).

Dr. SIDNEY PHILLIPS showed two cases of Associated Movement of the Upper Lid with Movement of Eyeball. The cases occurred in brothers, and was seen in one at the age of six months. The eyeball directed to one side, the opposite upper eyelid droops, and also on the side used, though this latter is rendered less apparent by an effort which contracts the occipito-frontalis muscle.

Mr. ROCKLIFFE related two cases of New Formation in the Vitreous: in the first case there was high myopia; in the second there was a history of a blow. There was no syphilis in either patient, and in each the eye was quite blind. He also narrated a case of Ossification of the Choroid, causing sympathetic ophthalmia. There was no history of syphilis or injury, but there had been an attack of kerato-iritis eight years previously. After removal an extensive layer of bony tissue extending in all directions from the site of the disc, the lens, which was entirely absorbed, was encapsuled in a bony shell.—The PRESIDENT observed that the first two cases were clearly instances of inflammation, and not new growth. He had seen true bone formation, but doubted if it was not in inflammatory products rather than in the choroid.

Drs. BRAILEY and HARTLEY communicated a paper on Tubercular (?) Disease of Choroid, with extirpation of both eyes. Five years previously the patient's left eye was struck with a piece of metal. No notice was taken of the accident; but in June, 1886, the eye was tender, and he applied for relief. A small triangular piece of metal was then discovered resting upon the iris at its lower part. Faint horizontal streaks of opacity were also visible in lower half of lens. The metal, with the iris to which it was adherent, was removed by a downward iridectomy, and the eye seemed to become quiet. In about a month, however, the patient returned, complaining of intense pain in left side of head, with some diminution of sight in right eye, which before was normal. Right eye: V ⅔, cornea bright, but surrounded by distinct zone of pink injection. No pain or photophobia in this eye; only "dulness" of sight. Left eye: Intense vascular injection of the whole eyeball, which appeared enlarged. Cornea uniformly opaque; tendency to bulging of iris at the upper and lower ciliary margins. V = *nil*. T + 2. This eye got rapidly worse, in spite of treatment, so that in a day or two it was extirpated. The right eye, meantime, was being vigorously treated with biniodide of mercury, leeches, atropine, &c.; but, on August 4th the notes said: "Pain in right eye and right side of head, much chemosis, V = barely fingers." On Aug. 21st there was marked prominence of the ciliary region; cornea slightly hazy (from altered T?); eyeball as a whole large and prominent. Iris swollen and pupil obliterated. T + ; V = *nil*. Pain and swelling continued. Eye eventually extirpated. Examination of eye by Dr. Brailey: Globe slightly enlarged (generally), especially in antero-posterior diameter. Cornea small, probably opaque, and flat when fresh. Extensive and prominent bulging of ciliary region, especially above and below. Anterior chamber was probably wanting or shallow when fresh. Optic nerve larger than normal. Antero-posterior vertical section through cornea and yellow spot showed the lens *in situ*: vitreous gathered up so as to occupy only the anterior half of its cavity; a thin fluid fills up the remaining space. Retina *in situ*, but thickened and much wrinkled. Choroid *in situ*, but much changed in appearance; at and near the posterior pole much thickened; this thickening closely surrounded the optic disc. It tapered off forward to the ora serrata, but even there it measured two or three times its normal thickness. Great thickening began again at the ciliary body, and extending thence to the iris, diminishing towards its pupillary margin, which hardly appeared implicated. In the iris the new growth appeared mainly posterior to the uveal pigment layer, which appeared scarcely altered. In the ciliary body the uveal pigment was scattered, and the new growth appeared both internal and external to it. The sclero-corneal tissue was abruptly thinned at the anterior termination of the ciliary body, and enormously stretched. This change extended over an antero-posterior space of at least five millimetres. The vastly thickened base of the iris was pushed close into the projecting part. Thus was constituted the ciliary bulging. A thin, pretty uniform layer of new formation and slight consistency was found between the retina and its pigment epithelium layer, and appeared to be due to the coagulation of a fluid effused in this position. The growth did not seem to have extended either into the substance of the sclerotic or into the retina, or to have perforated the lumina vitrea of the choroid. It was fairly consistent and non-pigmented.—The PRESIDENT thought the evidence of tubercle was indistinct: there was no history of it, and it was not proved by the microscope.—Dr. BRAILEY said that the growth in the second eye was clearly tubercular, there were well-marked giant cells and broken-down matter; no bacilli were found, but he laid no stress on that, as it might have been due to the Muller's fluid.—Mr. LAWFORD said that this did not interfere with the detection of the bacilli.—Dr. SHARKEY considered the anatomical peculiarities of tubercle much more characteristic than the bacilli; even in cases of general tuberculosis, he had failed to find them in any of the organs. The earlier the tubercles, the less the chance of finding them.—Mr. NETTLESHIP thought that, apart from the histology, a subacute destructive sympathetic inflammation would satisfy all the conditions found.—Mr. HARTLEY said there was nothing in the accident or in the behaviour of the first eye in favour of sympathetic inflammation.

Mr. SIMEON SNELL (Sheffield) read a paper on the Closure of Sclerotic Wounds by Suturing the Conjunctiva only, and said that for a long time he had been convinced that it was unnecessary and undesirable to suture the sclerotic directly for wounds of that tunic. Perfect apposition was obtained by suturing the conjunctiva only; a needle threaded with carbolised catgut or silk was passed well underneath the conjunctiva on either side of the scleral wound, and the grip thus obtained allowed, on tying the suture, the lips of the wound to fall into perfect apposition. The resulting union was perfect. He referred to his article in the *Ophthalmic Review* for 1884, where he related cases and advocated this method: more recent experience had confirmed his opinion as to its value. He had employed it in a large number of cases where he had incised the sclerotic to remove or search for foreign bodies with the electro-magnet, as well as in several cases of accidental wounds, examples of which he related. The method advocated avoided passing a suture through the sclerotic, choroid, and retina, and left no loop in the interior of the eye to act in some degree as a foreign body in a cavity where the vitreous was already broken up; it made the deep wound into a subcutaneous one; it did not disturb union by removing sutures; the insertion of needles in the sclerotic often increased the loss of vitreous; this was avoided.

Mr. JESSOP read a case of sudden and lasting Lateral Nystagmus, most marked when looking to the left. It was a man aged seventy, who came to the Central London Ophthalmic Hospital on Nov. 12th, 1886. Three days previously, he noticed, on waking up, that fixed objects moved and rocked laterally. His previous general health had been good, but he had been troubled with slight diplopia for fifty ysars, which he attributed to his aniso-metropia. For the last week he had been giddy, but had never fallen down.

Digitized by Google

No syphilitic history or signs. Fourteen years deaf with his right ear, and five years with left. Eyes: no apparent squint, and fields for diplopia showed the images very little distance apart. Lateral nystagmus most marked when patient looked to the left, scarcely seen when looking to the right. Pupils equal; act to light and accommodation. Hippus irregular as to time and degree, not synchronous with respiration, pulse, or nystagmus, and not altered by looking to the right or left. He said that, on looking to the left, objects passed to the left, but he did not see them come back again. The nystagmic movements were not increased by pressure on the ear, as in Dr. Hughlings Jackson's case in the Transactions of the Ophthalmological Society, vol. iii., p. 261. The nystagmus was increased by active movement, especially coming downstairs turning to the right. Knee-jerks normal. Heart: loud mitral systolic murmur. Urine normal. Mr. Cumberbatch had examined the ears, and said that the deafness was the ordinary deafness connected with chronic middle ear catarrh.

Dr. GOWERS first drew attention to the forms of Conjugate Palsy of the lateral movements of the eyes caused by disease on one side of the pons. The lateral movement was excited by the sixth nucleus on one side, acting through its own nerve on the external rectus, and through the posterior longitudinal fibres (and cells and fibres of the opposite third nucleus and nerve), on the opposite internal rectus. It was probable that these third nerve fibres did not actually arise from the sixth nucleus, but that their cells were connected with those of the sixth. It had been sometimes assumed that the centre for this lateral movement was the sixth nucleus, but this view was erroneous; the centre was possibly the superior olivary body, which, according to Betcherew, was connected with the sixth nucleus, the auditory nucleus, the cerebellum, and the spinal cord. There were three classes of palsy from disease of this region. 1. Paralysis of the sixth nerve only, from disease of its fibres within the pons, causing absolute palsy of the external rectus and deviation of the eye inwards. 2. Disease of the nucleus of the sixth, causing the total palsy just mentioned, with, in addition, loss of the associated action of the opposite internal rectus, so that this eye could not be moved inwards beyond the middle line, except in some instances, in convergence or alone; the facial nerve was also involved in these cases. (An instance of this form was described.) 3. Disease above the sixth nucleus causing palsy of the lateral movement of both eyes, but without the total palsy of the external rectus, and consequent deviation of the eye inwards, present in the first two forms. If the eyes were moved towards the opposite side, they could be brought back as far as the middle line, but not further. Thus the affected muscles could bring the eyes back from the position produced to the action of their antagonists, although they could not effect a primary movement. Hence, this return movement must be excited in some other way than through the path by which the same muscles caused a primary lateral movement. The excitation for the return movement was probably due to the influence of the centres of the opposite side. Thus, in disease of the right side of the pons, in which the eyes could not be moved to the right, if they moved to the left the centres on the left side excite the corresponding centres on the right side to bring the eyes back to the middle line; to move them further the interrupted right path was necessary. It was perhaps, a special instance of the associated action of opponent muscles, continuing longer in the centres for the opponents than in those for the primary movement. This consideration simplifies the problem of the immediate mechanism of nystagmus, reducing it to the causation of the intermissions of the primary contraction. Given intermitting contraction and the return movement, the oscillation necessarily followed. It was probable that a tendency to intermission was inherent in the centres, but was normally restrained, and the contraction rendered uniform by some influences, perhaps complex. One such influence might be the mutual action of opposing centres. A case was mentioned of disease of one side of the pons, with loss of the movement towards that side, in which there was nystagmus in the movement towards the opposite side; and, two years ago, he had brought a case before the Society in which an acute lesion on one side of the pons caused deviations towards the opposite side, with nystagmus. But many more facts as to the position of lesions causing nystagmus were required before the speculation as to its mechanism could, with profit, be carried further.—Dr. HUGHLINGS JACKSON, after remarking on the great value of the case Mr. Jessop had brought forward, and on the thoroughness with which it had been investigated, and after expressing his admiration of Dr. Gowers' paper, said that he had long held that nystagmus and tremor signified paralysis. He believed that, notwithstanding the complete excursions of the globes, there was loss of some few ocular movements in the case of Mr. Jessop's patient. It was of very great importance to distinguish between loss of power of muscles and loss of movements. In nystagmus there was, he thought, loss of some movements and development, and sometimes over-development of other movements of the very same muscles. He considered that in miners' nystagmus and in other professional cramps (writers' cramp, for example) there was loss of some movements, with forcing of other movements of the same muscles. If, after gazing out of a rapidly moving railway carriage, we look at the seat, the seat seems to move: here is negative after-movement; there is loss of a few ocular movements with over-development of other movements. Is there not here nystagmus in the making? It was submitted that there was temporary exhaustion of some cells of the lowest motor centres for certain ocular movements. If one might make the ridiculous supposition that a man's occupation consisted in looking out of a railway carriage window, he might come in time to have railway travellers' nystagmus, the genesis of which would point to a paralytic element—loss of some movements owing to atrophy of some cells of lowest motor centres, with over-development of other movements. Dr. Hughlings Jackson then adverted to a case of hemiplegia from disease of the upper part of one-half of the pons Varolii with turning of the eyes from the side of the lesion—that is, to the side paralysed—which had been investigated by Dr. Gowers and himself (*Medical Times and Gazette*, Jan. 3rd, 1874). It was well known that there were in cases of epileptiform seizures the mobile counterparts of ordinary hemiplegia with deviation of the eyes from the side paralysed. Dr. Jackson thought he had twice recently seen the mobile counterpart of the hemiplegia from disease of the pons he had mentioned; nearly tonic spasm of the limbs of one side with turning of the eyes to the other side, presumably depending on discharge beginning in some part of the pons. He mentioned the case of a boy, reported to the Medical Society in November last, who had fits when his head or face was touched. In the fits the eyes turned to the right; there was hemiplegia of the left side. A case of more direct ophthalmological interest was that of a patient who had paroxysms of lazy clonic, almost tonic, spasm of the right side of the face, but of the two obiculares palpebrarum, and turning of the two eyes to the left. Fully aware that face fits occurred from limited discharges of the mid-cortex, he believed the face fit mentioned to belong to the class of ponto-bulbo-spinal fits (lowest level of evolution). The work the ophthalmologists were doing in precisely distinguishing losses of ocular movements from paralyses of ocular muscles was of vast interest to the neurologist. Dr. Jackson had never seen loss of ocular movements in cases of general paresis, except perhaps in one case in which there was a want of smoothness in the excursions of the globes, not amounting to nystagnus. Theoretically, loss of some movements would be expected, and, theoretically, a change so slight as not to amount to that supposed to occur in nystagmus.—Mr. PRIESTLEY SMITH suggested that the correspondence in the direction between the ocular movement and the displacement of the images of objects might be explained by the patients not perceiving the image of external objects during the spasm, but only on the return of the eye to its former position. As to the occurrence of hippus in the conjugate lateral movement, he asked whether it occurred during convergence. Did cases of convergent nystagmus exist? He had not seen one. From the nature of the nystagmus we should suspect that it originated from disturbance of motor centres situate at a lower level than those which were producible by voluntary effort. He had seen one case only of vertical nystagmus. Von Graefe referred to six. As supporting Dr. H. Jackson's view, that nystagmus was in one sense of the nature of a paralysis, he said that normal movements of the eye might easily become of a jerky character. In gazing at the sun, for instance, and then looking at the landscape away from the sun, he had always noticed that the negative image of the sun had the appearance as of a number of dots, which he ascribed to displacement, the result of disturbed innervation of the

Digitized by Google

muscles.—Mr. W. H. JESSOP, in reply, said there was hippus during convergence, and in right lateral deviation also.—Dr. GOWERS, in reply, alluded to the fact that in nystagmus objects sometimes appear to move in the same direction as the quick movement of the eye, as of great importance as probably affording grounds for ultimately distinguishing the functional relations of the phenomenon in different cases. It brought the movement into relation with vertigo, with which it is sometimes associated, and in which the sense of movement in the individual and in external objects usually agrees in direction. The explanation of the agreement is to be found in the motor character of vertigo, and in the fact that any resulting movement is secondary, and falls short of the actual motor tendency which is felt as a sensation. If a person turns round, and an object remains opposite to his eye, he infers that the object moves in the same direction as he does, and a sensation of movement leads to the same inference; actual movement would only prevent the inference if it were equal to the tendency, and there would only be a sensation of movement in the opposite direction if the actual movement were in excess of the tendency.

OBSTETRICAL SOCIETY OF LONDON.

Galactorrhœa.—Mechanism of the Third Stage of Labour.

AT the meeting on March 2nd, Dr. GALABIN showed a Uterus removed in November last by Porro's operation. The patient made a good recovery.

Dr. HORROCKS exhibited a Fibromyoma from a case of Cæsarian section. The patient in this case died.

The President, Dr. JOHN WILLIAMS, delivered the Inaugural Address, which will be found on another page. At the conclusion a warm vote of thanks was proposed by Dr. GRAILEY HEWITT and seconded by Dr. BRAXTON HICKS, which was carried by acclamation.

The discussion of the paper on Galactorrhœa, which was read at the previous meeting by Dr. Gibbons, was opened by Dr. MATTHEWS DUNCAN, who noticed the neglect of the science of lactation and deficiency of literature connected with this important and interesting department of practice. He believed Dr. Gibbons' paper to be the fullest account of the subject. Galactorrhœa required definition, for there were many kinds. That prolonged and exhausting suckling which led to depression and melancholia might be, but was not classed as, galactorrhœa. In Dr. Gibbons' case there was no excessive flow, for thirty ounces a day could only be regarded as a long continuance of the flow in quantity nearly what was secreted by an actively nursing woman. Dr. Duncan had seen in a healthy young woman a constant flow so excessive as to run through the bed and over it to the extent of many pints a day, but not for many weeks. Another kind of excessive flow was not very rare in rich-blooded young women—milk running from the idle breast while the other was being sucked. He had watched such a case where the wasted milk was apparently more than the child could be swallowing, the flow going on only while the opposite breast was stimulated by the sucking infant. The unilaterality of Dr. Gibbons' case was interesting but it was not rare in ordinary healthy nursing. In Dr. Gibbons' case cure came at once on the appearance of delayed menses, and it was most natural to ascribe the arrest of lacteal secretion to the appearance of menses, the one function alternating with the other as the growth of stags' horns with the rutting.—Dr. CLEVELAND drew attention to what he preferred to call "incontinence of milk." In this condition the infant at the breast would cry more than usual, not being satisfied; it did not sleep so long as it should, and did not present the appearance of thriving. On inquiry as to the suckling, the frequent reply is that "there is plenty of milk and that it runs away." Dr. Cleveland was satisfied that where a primipara suffered from this form of galactorrhœa she would prove an inefficient nurse.—Dr. JOHN PHILLIPS mentioned a case, as did Dr. HORROCKS, and the latter compared the physiology of secretion of saliva with that of milk, and suggested that galactorrhœa might be due to vaso-motor or pure nerve influence. The secretion of milk was intimately associated with the ovaries, but the nervous pathology had not yet been fully ascertained.—Dr. C. H. ROUTH asked why local pressure of the breast was not carried out in these cases. It was a well-known method of treatment in cases of orchitis or swollen limbs. Dr. Routh mentioned a case in which a lady continued to secrete milk long after the weaning of her child, and which persisted some three years and then became restricted to one breast. It yielded partially to treatment by pressure, but completely stopped when treatment was directed to the womb. He thought that by the introduction of a piece of caustic within the uterus, as suggested by Sir James Simpson, the flow of blood or menses might have been determined and the cure of nature anticipated.—Dr. PLAYFAIR knew a good deal of the practice of the late Sir James Simpson, but was not aware that he ever adopted or recommended the treatment named by Dr. Routh.—Dr. GALABIN and Dr. DAWSON related their experience.—Mr. J. BLAND SUTTON said he had found galactorrhœa in the cow due to tubercular disease of the ovaries, and in a case of unilateral galactorrhœa in a kid there was a cystic ovary on that side.—Dr. HERMAN asked if the mammary abscess from which Dr. Gibbons' patient had suffered might not be the explanation of the unilateral character of the galactorrhœa, one breast not secreting because of destruction of gland tissue by the abscess.—Dr. CHAMPNEYS said that Dr. Gibbons' case exemplified the antagonism or alternation between lactation and menstruation. There were cases in which secretion of milk coexisted with uterine hæmorrhage.—He had seen a case in which the more the breasts swelled the greater was the uterine loss. Nursing was stopped, ergot given, and the breasts soon subsided. With regard to treatment, Dr. Champneys could not see why eczema need have prevented the application of pressure. A drying powder on lint or cotton-wool could have been used, with strapping over, the straps reaching more than half round the body. He thought there was evidence in favour of the use of ergot in these cases. Derivation to the uterus by hot foot-baths was also not mentioned. Dr. Champneys could imagine that uterine hæmorrhage might be caused by the introduction of caustic within the womb, as named by Dr. Routh, but such hæmorrhage could not be considered menstruation. Dr. Champneys had heard of wholesale spaying of milking-cows in Texas, with the result that the milk had gone on to the owner's satisfaction for a long time, in one case for eleven years.—Dr. HEYWOOD SMITH thought the discussion would lead us to give more attention in such cases to the condition of the uterus and ovaries.—Dr. W. J. COLLINS had seen lacteal secretion in infants, male and female. He would like to hear what the condition of the breast was in Dr. Gibbons' case after the arrest of secretion. Was it atrophic? From analogy with the salivary glands the galactorrhœa might be of the nature of a paralytic secretion.—In reply, Dr. GIBBONS said that the eczema was due to constant saturation of the skin with the milk that flowed away, and that his case was so entirely unilateral that not a drop of milk could be squeezed from the right breast. When the patient was well the left breast assumed a normal appearance.

Dr. CHAMPNEYS read the first of a series of papers on the Mechanism of the Third Stage of Labour. 1. The Separation of the Placenta, reviewing the facts furnished by our knowledge of the clinical course of natural labour, and by that derived from Porro's operation. From the former it is known that until the birth of the head the placenta is not detached, and that after the birth of the head it is not at once detached. Leenser found by examination of 168 women that the placenta is completely detached as soon as the child is born. As regards Porro's operation, the inferences drawn from it must be regarded with suspicion on account of the great interference which has taken place with the uterus. The facts derived from these two sources do not tally. He next discussed the theories of the cause of placental detachment. *A.* By contraction and retraction alone, through reduction of the placental site. *B.* By contraction and retraction indirectly. (*a*) By separation of the centre, which is less firmly attached than the edge, leading to aspiration of blood; (*b*) by squeezing blood towards the surface during contraction; (*c*) by rapid diminution of intra-uterine pressure consequent on the birth of the child. *C.* By detrusion (Leenser), the placenta being forced in the direction of least resistance—i.e., the axes of the parturient canal. He then reviewed the theories of the modes of placental detachment. *A.* According to the situation of the placenta. *B.* From edge. *C.* From centre. *D.* According to firmness of attachment of its parts, and to the question whether the separation of the placenta is independent of rupture of utero-placental vessels as a cause, the decision depends (*a*) on proved hæmorrhage behind the placenta in normal labour; (*b*) on

Digitized by Google

the mode of expulsion of the placenta. Pending the decision of the above questions to be dealt with in a subsequent paper, Dr. Champneys concluded that hæmorrhage to a moderate amount plays a certain though subsidiary part in the mechanism of the detachment of the placenta.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

AT a meeting held at the Scottish Corporation Hall, Crane-court, Fleet-street, on Friday, Feb. 18th, Dr. Alfred Hill, President, in the chair, a paper was read, entitled "A Practical Illustration of the Protective Influence of Vaccination," by C. E. PAGET, medical officer of health for the Westmoreland Combined Sanitary District. The paper had reference to an outbreak of small-pox in a village in Westmoreland and its neighbourhood, and details of each case were very carefully given. The outbreak had lasted from March to September, 1885, the disease having first appeared outside the village in a sparsely inhabited hill district, and then found its way into the village, where it attracted attention. The early cases outside the village, numbering nine, were not seen by a medical man, except one, on a single occasion, in an incipient stage of illness before the rash was out, and it was not till severer cases occurred on the introduction of the disease into the village that medical advice was sought. The total number of cases in the outbreak was seventeen, and there was no mortality. All the cases showed marks of "pitting." The chief point of hygienic interest in the outbreak seemed to be in the illustration it afforded of what has been noticed in other outbreaks of infectious sickness, such as scarlet fever, diphtheria, and measles, especially in scattered rural districts—that the spread of such diseases may be often largely due to the mildness of initial cases. With respect to the influences of previous vaccination upon the outbreak, the paper was illustrated by several tables, and showed, first, that all persons that might be said to have been unvaccinated sickened; second, that one child only out of nine under fourteen years of age that had been primarily vaccinated, and had been definitely exposed to infection, sickened; third, that thirteen persons out of twenty-two over fourteen years of age that had been primarily vaccinated sickened (though the numbers might more fairly be taken as thirteen out of nineteen, since three adults were not exposed to nearly the same degree of infection as the others); and fourth, that the only (though very poorly) revaccinated adult sickened, but only in a moderate degree. The chief practical interest of the epidemic in respect of the partial protection of persons seemed to be in the enormous mitigation of illness, even where there was incomplete vaccination and a general want of revaccination. It was in the highest degree unlikely that if there had been an absence of even a partial vaccinary protection the attacks of small-pox would have been mild, and that in such a circumstance, in spite of the distances between the patients and medical advice, they would not have come under medical treatment. Such an epidemic history could scarcely have been given but for the half measures of protection enjoyed by the community of whom it was told.—In the discussion which followed the President, Drs. Gibbon, Louis Parkes, Sykes, Yarrow, and Ashby, and Messrs. Butterfield, Lovett, Eyre, and Murphy took part.

ACADEMY OF MEDICINE IN IRELAND.

Aspergillus Nigricans.—Dermoid Tumour.—Œdema Glottidis.

AT the meeting of the Pathological Section held on Jan. 14th,

Mr. STORY exhibited and described microscopic specimens of Aspergillus Nigricans, which he had removed from the auditory meatus of three individuals suffering from deafness and inflammation of the external ears. He exhibited also a fourth fungus of an undetermined character, but most probably also one of the aspergillus tribe. He gave a brief *résumé* of the literature of the subject of otomycosis, and stated his conviction that the fungi were the cause and not the consequence of the ear disease—a view which had been advocated by some of the writers on the subject.—Dr. MAPOTHER mentioned that in the year 1880 he himself had an acute attack of this otomycosis. He had never suffered, either before or since, from any aural disease. One night he went to bed in a house in the suburbs of Dublin with his hearing perfect, and the following morning he arose almost completely deaf. He bore the affection for one day, and on the next consulted Mr. Swanzy, who, partly by means of forceps and partly by syringing, removed a quantity of white cottony material from his ears. Besides the deafness, the only sensations he had were stuffing and a sort of ramming, as if something like cotton-wool was being pushed into both ears. The material removed from his ears was examined by himself and his friend, the late Dr. Richardson, and they both came to the conclusion that it contained aspergillus. After the extraction of the fungi from his ears, and a week's washing with sulphurous acid lotion, they disappeared and never grew again. He had observed that the wall paper of the room, next to which he slept, was extremely damp and almost completely separated from the wall by the dampness; and he believed that it was that which produced the fungi. Since the wall had become dry no similar attack of mycosis had occurred to anyone else occupying the room.—Mr. STORY, in reply, said he remembered having, as a patient suffering from this disease, a farmer who, sitting up all night with a sick cow, had stuffing and pain in his ears next morning, which were found to be caused by aspergillus.

Mr. STORY also exhibited a Dermoid Tumour growing from the corneo-scleral margin of the left eye of a middle-aged man. The tumour was of a pinkish-yellow colour, and had one long hair growing out of its centre. No other hairs could be detected, even with a magnifying glass. The tumour had existed ever since the man's birth, and remained quiescent until two months ago, when it began to grow over the surface of the cornea. It was a flat sessile growth, of a circular shape, about 4 mm. in diameter, half corneal, half scleral. In his opinion, it was to be regarded as a dermoid growth.

Dr. CHRISTOPHER NIXON exhibited the larynx and trachea of a patient who had died under his care of what is it the custom to call Œdema Glottidis, occurring in the course of Bright's disease.—The PRESIDENT observed that whether or not the disputed point was conceded that in Bright's disease the large smooth kidney might, in process of time, change to the small contracted kidney, there was no difficulty in assuming that other cases might occur in which that change did not happen. He would have no difficulty in accepting a history of any number of years' duration of Bright's disease, and yet in finding a large smooth kidney after death. He did not think anyone maintained that the large smooth kidney necessarily turned into the small kidney. The point in dispute was whether the small kidney ever represented a large kidney which had undergone atrophic change. But that a large kidney might remain so for an indefinite time was no subject of wonder.

Reviews and Notices of Books.

Diseases of the Joints. By HOWARD MARSH, F.R.C.S., Senior Assistant-Surgeon to, and Lecturer on Anatomy at, St. Bartholomew's Hospital; Senior Surgeon to the Hospital for Sick Children and to the Alexandra Hospital for Hip Disease. With 64 Illustrations and a Coloured Plate. London: Cassell and Co. 1886.

THE volume before us is one of Messrs. Cassell's series of Clinical Manuals. It avowedly deals with diseases of joints from a clinical as opposed to a pathological point of view, and is mainly taken up with a description of diagnosis and treatment. Such pathology as is given is the work mainly of Mr. A. Bowlby, who is well fitted for such a task. We could have wished that he had had more space allotted to him, for there are several points in the pathology of diseases of joints which merit a fuller discussion than they receive in Mr. Marsh's book. At the same time we have to remember that a limit was necessarily imposed upon the author, and we cannot question his wisdom in preferring to make his book clinical rather than pathological. Mr. Marsh's experience at St. Bartholomew's Hospital and at two other hospitals has enabled him to

Digitized by Google

enrich his chapters with many excellent clinical histories which admirably illustrate the diseases he describes, and this feature of the book is sure to make it popular with most readers. Altogether the work is pleasant reading, practical, and trustworthy. The general teaching of Mr. Marsh is that with which the majority of English writers are more or less familiar. He does not advocate novel or radical procedures, and it is for this very reason that the book will be most acceptable to the majority of practitioners, who will be told how to treat articular affections without resorting to formidable operations. The chapters on the early recognition and treatment of Scrofulous Disease of Joints, on Syphilis of Joints, on Internal Derangement of the Knee, and on Bone-setting, seem to us to be some of the best in the book, while that in which the Injurious Effects of Intra-articular Pressure are described is well worthy of study. The early chapters on Synovitis &c. might have been arranged in a more systematic manner, and in them we think we notice a few omissions—such as the absence of any mention of over-use and of wounds among the causes of simple synovitis, or of heat as a local application in acute suppurative arthritis, the omission of any notice of the value of antiseptic irrigation of joints, and the omission of any treatment for purulent synovitis as distinguished from acute suppurative arthritis. These are, however, minor defects, and should in no way blind us to the fact that Mr. Marsh has produced a readable and useful work on a subject of the very highest importance. The illustrations are not of a high order of merit; the coloured plate which is said to represent a knee-joint affected with Charcot's disease may be that or anything else, and, whatever it is, it fails to give any adequate conception of the changes met with in this remarkable disease.

Leçons sur les Maladies du Système Nerveux. Par J. M. CHARCOT. Recueillies et publiées par MM. BABINSKI, BERNARD, FÉRÉ, GUINON, MARIE, et GILLES DE LA TOURETTE. Tome III. (2ème Fascicule). Paris: A. Delahaye et E. Lecrosnier. 1887.

WE owe the collection of M. Charcot's lectures, delivered at the Salpêtrière, of which the present forms the conclusion of the third volume, to the devotion of his friends and pupils. They are lectures which are classical and will have a permanent place in literature. Many of them have appeared from time to time in the pages of our contemporary *Le Progrès Médical*, whose editor, M. Bourneville, was associated with the production of the first volume of this notable series. It is interesting to note how M. Charcot has gradually in the course of his teaching tended to pass from the region of structural to that of functional disease. Thus, in the present volume there are several lectures devoted to male hysteria, isolation in the treatment of hysteria, hysterical paralysis, hysterical coxalgia, contracture and mutism; two others to word-blindness; another upon a case of abrupt and isolated suppression of the mental vision of signs and objects (form and colour), and on choreiform tremors and movements; while as to organic disease, there is one lecture on double sciatica in cancer, and cervical pachymeningitis, and another on a nosographical revision of amyotrophy. Some of the subjects are further dealt with in an appendix, affording additional observations upon the particular points treated of. Interesting as the subject of hysteria always is, and practically important as the recognition of its various forms must always be, it cannot but be felt that among less emotional races the remarkable phenomena described by M. Charcot as exhibited by the hysterical are to be rarely witnessed. These lectures, therefore, may attract less universal attention than those earlier ones which did so much to enlighten the medical world upon the pathological nature of organic disease of the brain and spinal cord. But if they fail to be so widely read, it is not that they do not merit it, for they exhibit in their clear and well-considered language the same vigour of treatment and masterly exposition that constitute the great charm of all Professor Charcot's writings. As in the domain of organic disease, so in the more intricate and complex region of functional derangement, Professor Charcot cannot but be regarded as a pioneer, whose observations are always exact, and whose ideas are at once sagacious and fruitful.

OUR LIBRARY TABLE.

The Factors of Organic Evolution. By HERBERT SPENCER. Pp. 76. London: Williams and Norgate. 1887.—This small volume is a reprint of two essays originally published in the *Nineteenth Century* for April and May of last year, in which Mr. Spencer endeavours to show that there are several factors in the process of evolution which have been allowed to drop out of view owing to the followers of Darwin having too exclusively devoted themselves to the single factor of natural selection of favourable variations. He thinks that one important factor thus neglected has been the inherited changes induced in structure owing to modification of function, as by the excessive use or disuse of parts, such changes being inheritable, so that, for example, "any change in the fore parts of a giraffe which affects the action of the hind limbs and back will simultaneously cause, by the greater or less exercise of it, a remoulding of each component in the hind limbs and back in a way adapted to the new demands; and generation after generation the entire structure of the hind quarters will be progressingly fitted to the changed structure of the fore quarters, all the appliances for nutrition and innervation being at the same time progressively fitted to both." Another factor, he considers, is the direct action of surrounding agencies on organic life, which in its varying influence on different members of the same group must always have tended to differentiate individuals and led to the formation of types or species.

The Quarterly Journal of Microscopical Science.—Edited by Professor E. RAY LANKESTER, THISLETON DYER, KLEIN, MOSLEY, and SEDGWICK. New Series. No. CVII. (Vol. XXVII., Part 3). London: J. and A. Churchill. 1887.—This part contains the following memoirs:—Gilbert Bourne, on the Madreporian Coral Fungia, with three plates. 2. Arthur Shipley: Some Points in the Development of Petromyzon Fluviatilis, with four plates. 3. Robert Smith: The Ammoniacal Decomposition of Urine, with two illustrations. 4. Herbert Carpenter: Notes on Echinoderm Morphology, with an illustration. 5. R. v. Lendenfeld: The Function of Nettle Cells, with an illustration. 6. Hanbury Hankin: Some New Methods of Using the Aniline Dyes for Staining Bacteria. 7. Marshall Ward: Illustrations of the Structure and Life History of Phytopthora Infestans, the Fungus causing the Potato Disease, with two plates. 8. Martin Hartog: The Formation and Liberation of the Zoospores in the Saprolegniæ. Dr. Smith has made a series of experiments to determine the cause of the decomposition of urea, and finds that it is owing to the presence of a special form of microbe belonging to the micrococci, which differs from the micrococcus ureæ of Professor Leube, inasmuch as it liquefies gelatine.

Vision and Vision-testing, with Practical Tests. By A. ST. CLAIR BUXTON, F.R.C.S., Assistant-Surgeon to the Western Ophthalmic Hospital, London. Pp. 83. London: Pickard and Curry. 1887.—Mr. St. Clair Buxton supplies in this little work a popular and very brief account of the anatomy and physiology of the eye. A novelty is introduced in the shape of a figure showing the mode of formation of distinct and indistinct images upon a screen of a candle flame by means of a lens. The fact which will prove most serviceable is the account of the tests to which

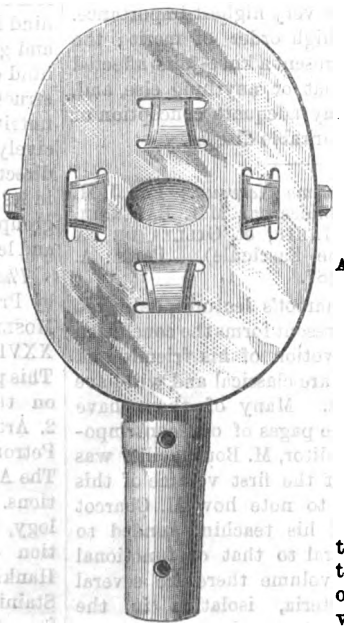
Digitized by Google

Government officials are now subjected, and which, if every intending clerk were to try upon himself, would spare much disappointment and annoyance.

Obstetrical Transactions. Parts I., II., and III., for 1886.—The Obstetrical Transactions for 1886 fully maintain the character of the series as a record of interesting cases, and, more important still, as a result of solid work done by the Fellows. In this work we are glad to find seniors and juniors happily united in friendly rivalry, some of the communications being the result of investigation spread over several years. The appearance of the Transactions in parts is a decided improvement, as the matter is more easily assimilated in detail, and is laid before the medical world in a tangible form before it becomes stale. Among the more important scientific papers we may mention those by Dr. Herman on the Oblique Pelvis of Naegele (January), and on one of the causes of Difficulty in Turning; by Dr. Matthews Duncan on Contraction, Inhibition, and Expansion of the Uterus (April), and another on Elasticity, Retraction, and Polarity of the Uterus (May); by Dr. Champneys on the Artificial Production of so-called "Lymphatic Varix" (June), and Observations on the Uterine Bruit (July); by Dr. John Phillips on Spurious Hermaphroditism (with a remarkable family tree); and by Mr. Doran on Malformations of the Fallopian Tube (July). Among the most interesting cases the following may be named:—Gastrotomy for Extra-uterine Gestation in which the placenta never came away, by Dr. Braithwaite; Removal of both Ovaries during Pregnancy, by Mr. Thornton (February); Multiple Fibromata complicating Twin Pregnancy, by Dr. John Phillips (June); and Chronic Abscess of the Urethra, by Dr. Herman. Of the specimens shown, the following are of interest:—Gestation in one Horn of a Uterus Bicornis Unicollis, by Dr. Campbell Pope (March); a Series of Uteri at the Onset of Labour and After Delivery, by Dr. Barbour (March); and a Naegele Pelvis, by Dr. W. Griffith (April). We congratulate the Society on so creditable an amount of work done during nine months. The final part of the Transactions is still to come.

Archiv für Pathologische Anatomie und Physiologie. Herausgegeben von RUDOLF VIRCHOW. Bd. 107, Heft I. Berlin: G. Reimer. 1887.—The January number of Virchow's *Archiv* contains the following articles: 1. On the Influence of Hardening Methods upon the Condition of the Ganglion Cells of the Spinal Cord in the Rabbit and Dog, by Dr. Trzebinski. 2. Researches on Heat-radiation of the Human Body, by A. Masje. 3. The Structure of Fœtal Membranes in Abdominal Pregnancy, by Dr. A. Walker. 4. On the "Reducing" Substances in Diabetic Urine, by Dr. Hans Leo. 5. Contribution to the Doctrine of Trophic Nerves, by Dr. Max Joseph. 6. The Fascia Umbilicalis and its Connexion with Umbilical Hernia in Children, by Dr. H. Sachs. There are also some minor contributions by various writers.

Centralblatt für Bacteriologie und Parasitenkunde. Herausgegeben von Dr. O. UHLWORM in Cassel. Bd. I. Nos. 1 and 2. Jena: J. Fischer.—The activity of bacteriological research has led to the issue of a "Centralblatt," which is to appear weekly. The editor, Dr. Uhlworm, acts in co-operation with Professor Leuckart of Leipsig and Dr. Loeffler of Berlin, names which will sufficiently guarantee the high character of the journal. Professor Leuckart contributes an original article upon the Bothriocephalus question, which occupies the first place in each of the first two numbers, the remaining pages being devoted to abstracts and reviews of recent work. The second number also contains a list of recent literature compiled by Dr. Würzburg, librarian to the Imperial Sanitary Institute.



Revue Générale de Clinique et de Thérapeutique (*Journal des Praticiens*) is a new journal, of which the first number appeared on the 17th ult. It is published every Thursday, and its chief aim is to supply within a small compass all that is of special interest to the actual practitioner. The official address is 16, Rue Clément Marot; the chief editor is M. Huchard, and the acting secretary M. Eloy. The first two numbers are very well done.

New Inventions.

EMPYEMA-TUBE.

A TUBE which will provide satisfactory drainage in cases of empyema has long been a desideratum. The simple indiarubber tube is liable to have its calibre obliterated by the pressure of the ribs, or thickened pleura in long-standing cases, or by becoming kinked just inside the chest wall. The ordinary silver empyema-tube does not adapt itself well to the varying conditions of the chest, and often causes injurious pressure on the lung. The silver tube I have had made is non-compressible, cannot become kinked, will fit any chest, is comfortable to the patient, and keeps well in position. It is composed of a shield (A) measuring two inches by one inch and a half, and a lobster-tailed tube (B) attached at right angles to it. The shield gives a firm base of support to the tube, and prevents it from slipping into the chest, while the pressure of the dressings on the broad surface guards against any untoward displacement. The lobster-tailed tube (B) is two inches long, with an oval bore of half an inch by a quarter of an inch. The joints nearest the shield are made especially mobile, to enable it to fit accurately round the inside of the ribs and pleura. It has several openings to give exit to the fluids. Over the silver tube one end of a thin piece of indiarubber tubing of the required length can be drawn; the outer end of this tube is slit into four parts, each of which is passed through two slots in the corresponding side of the shield (A). This arrangement fastens the two tubes securely together. In practice I have found this tube answer all my expectations. Great care must be taken, on account of its numerous joints, to purify it thoroughly. It is made in three series by Messrs. Ferris and Co. of Bristol, one larger and one smaller than the above. I have found it advisable, however, to use as large a tube as possible.

THE LANCET.

LONDON: SATURDAY, MARCH 19, 1887.

THE complaints which have from time to time been made as to erysipelas after vaccination are evidently leading to a careful examination of all the circumstances associated with such occurrences, and the report which has recently been submitted to the Local Government Board by Dr. AIRY on three cases of fatal erysipelas after vaccination in the Sudbury Union is fairly typical of the facts which are usually elicited. The three cases occurred in October and November of last year, the deaths taking place on the 2nd, 9th, and 11th of November respectively. The three children were vaccinated by three separate medical practitioners, two of them being public vaccinators. In all three instances the operators performed the vaccination with all the needed care, and except as regards time and general locality the cases had nothing in common. Moreover, in each case other children had been vaccinated with the same lymph, and this without the occurrence of any untoward symptoms.

In the first case the vesicles were first broken accidentally after the eighth day, and it was after this followed by spreading erysipelas, which caused death. But rupture of vesicles, as Dr AIRY points out, is not sufficient to cause erysipelas, otherwise the intentional opening of vesicles would often be ollowed by a similar result. The poison, the contagium, the seed of erysipelas must be implanted into the scratch or wound thus induced. And it should be noted that if the erysipelas had been inoculated when the operation was performed, it would have shown itself at a much earlier date than the second week. The introduction of the poison took place after the accidental rupture of the vesicles, but beyond the fact that the infection of erysipelas was about in the town and neighbourhood, nothing to prove the occurrence of the infection could be ascertained. The child, however, lived in a spot where a low form of sore-throat was common. In the second case, which had no apparent connexion with the first, vaccination had been performed with calf lymph, and the child was well on the eighth day, when on inspection it was found that the vesicles had been broken. In this case the surroundings of the house were found to be insanitary; the mother had recently suffered from abscess of the arm; the father had an ulcer of the leg; when the child was brought to the surgery for inspection, a woman was sitting in the waiting-room with erysipelas of the face, and the practitioners connected with the case were at the time attending a case of erysipelatous inflammation of the leg, also a child with erysipelas, besides two cases of scarlet fever. Such facts abundantly account for the erysipelas in the vaccinated child. In the third case no definite source of infection could be discovered, but the child lived in a low-lying place close to swampy and unhealthy meadows.

In connexion with the origin of these cases of erysipelas, it is curious that in October and November three fatal attacks of the same disease after vaccination took place in the same union; and the indications also pointed to an endemic prevalence of erysipelas last autumn, a considerable amount, together with undefined sore-throats, being recognised. Under these circumstances, the wound produced by a lancet-scratch, or by a ruptured vesicle, is liable to receive the infection of erysipelas just in the same way as is any other wound. And this raises the question whether vaccination accidents are at all frequent preliminaries to erysipelas. This is answered by an instructive note which is placed at the head of the report by Dr. BUCHANAN. Taking septic diseases registered as having followed vaccination, Dr. BUCHANAN points out that in England and Wales during 1883—the latest period for which comparable official data were available—the number of infants receiving scratches or pricks in the process of vaccination was 763,192. The operation was followed by ill consequences in certain of these children, and 51 of them died, all or almost all from septic diseases. Now, in England and Wales the number of infants under one year of age was in 1883 over 760,000. By one mischance or other, but apart from any recorded connexion with vaccination, a certain number of these children became the subjects of septic disease, and of that number 724 died before completing one year of age. The facts may well be borne in mind, for they point to the circumstance that whilst a vaccination scratch is, like any other wound, liable to receive the erysipelatous poison, this result is really a rare one when compared with erysipelatous and septic occurrences following on other causes. The report[1] in which the facts recorded are set out has been placed on sale as an official publication.

THE committee which has been appointed to consider how best to organise medical attendance on the working classes in London has a difficult task before it, and will have many critics. We have reported from time to time the main conclusions reached, and it is to be admitted that the committee in these conclusions shows a perception of some of the chief rocks upon which the Metropolitan Medical Provident Association struck. They have agreed on a wage limit and upon terms of admission during sickness which it is thought will be, while not discouraging to providence and forethought, enough to induce those actually in need of medical attendance to join the dispensaries. We do not propose at present to discuss all the resolutions of the committee, but rather to emphasise the importance of a question which they are approaching, and which they must discuss at either the next meeting or the one immediately following—viz., the possibility and the advantage of co-operation between the hospitals and the provident dispensaries. It is thought by many that the out-patient department of hospitals is greatly abused, and that many of the patients so treated ought to be refused treatment there and relegated on system to the provident dispensary nearest to their homes—a point to be ascertained by a list of such institutions to be kept in each out-patient room of the various hospitals; and that the dispensaries, on the other hand, should be in close and organic relations with hospitals, and their officers have the power to ask

[1] Eyre and Spottiswoode, East Harding-street, E.C.; Adam and Charles Black, Edinburgh; Hodges, Figgis, and Co., Dublin.

Digitized by Google

consultation and co-operation with the medical staff of hospitals in all cases of difficulty or severity.

The medical staff of hospitals will do well to consider this proposal in a kindly spirit. They will perceive at once some of the objections to it, and be apt to imagine the out-patient rooms deserted, and its usual occupants crowding to the nearest provident dispensary. With this change they will be likely to apprehend diminished means of teaching common diseases, which are alleged already to be insufficiently studied and taught at hospitals; and the financial authority of hospitals may say that it is no business of theirs to inquire into the social condition and means of patients, and to serve as promoters and feeders of provident dispensaries. Such objections will not, we feel sure, be pressed too far. The hospitals are too great in their function, and in their services to the public and to the poor, to need to fear lest they should be left unsought. The more serious cases will still repair to them in numbers; and by enabling the medical officers to treat them with more thoroughness than is possible now with promiscuous crowds in the out-patient rooms, greater credit will redound to the hospital, and greater gratitude be forthcoming from patients. We have never been insensible to the vagueness of the charges of abuse of hospitals. The million of patients in London out of its five millions has always appeared to us as a most misleading statistic, including, as it certainly often does, the same patient over and over again in the same institution, admitted under different letters, and also the same individual as a patient in different institutions. But it is an undoubted fact that many persons frequent the out-patient rooms of hospitals who can afford to pay a private practitioner, or who ought to come under a system of insurance against medical bills, which it is the object of provident dispensaries to enable those of small means to avoid. And we do not know any way in which hospitals would do better service than by co-operating in a systematic and organised attempt to eliminate such persons from their patients. They would not only be lessening the heavy demands on their own funds, but by showing a disposition to co-operate for the removal of the only abuse seriously charged against them they would make their claim on the liberality of the public incontestable. We look forward with much interest to the discussion of this question by a committee, including very influential members of the profession who, with singular disinterestedness, have tried to view it in all its bearings.

THE Trade Depression cloud has not yet passed away, although the Report of the Royal Commission is rapidly descending into the limbo of forgotten things. It is true that a more hopeful tone prevails among the *vates*, and the opinion has now become current that if Europe can keep out of war, it will shortly enjoy in a large measure the commercial results of peace. Happily, although the risk of war is still undeniably great and even disquieting, it is yet open to us to hope that both the condition and the promise will be fulfilled. In that fulfilment the professional classes, and especially that of medicine, have a much nearer and livelier interest than is perhaps generally supposed. It is very commonly assumed that, as the state of trade affects them only indirectly for the most part, they can only be slightly interested in it, whether as sentimentally sharing the sufferings of their neighbours or as practically involved in the hardship of overdue accounts and bad debts. But in point of fact this is only half of the mischief. Another and more permanent inconvenience is the overcrowding which it produces in the ranks of the professional classes. The clouding over of the commercial horizon causes hundreds of youths, who in happier circumstances would have found their places in the van of the trading community, to divert their energies into what looks at the time the fairer field of professional toil. It does not strike them, until in after years their mutual competition has involved them all in a common disappointment, that the equation of supply and demand holds as rigorously true in the schools and the forum as in the mart; and then enlightenment has come too late. The generation must pass away before the consequences of such an incursion can wear off. Thus the effect upon the career of an ordinary professional man, if less direct, is much more lasting than on that of the ordinary commercial man. The disorder does not assume quite such an acute form, but it is less amenable to remedies, and certainly no less trying to the body politic. We make no claim, therefore, to the praise of altruism in respect of the keen interest taken by medical men generally in the subject upon which the Royal Commission so lately reported, and with so little apparent effect.

There is, indeed, one suggestion made by the Commission which seems to be in a fair way of yielding fruit, and it happens to be the one in which medical men have perhaps the most direct interest. It is that which relates to the amendment of the Joint-Stock Companies Acts. In the suggestion we heartily concur, regretting only that the Commissioners were not more explicit and precise as to the remedy to be applied. That, however, is a defect which can easily be repaired. Already a deputation of practical men has interviewed Lord SALISBURY, and had the opportunity of explaining to him the defects in the law to which experience points. He has replied that the Government proposes to deal with this matter in the way of legislation, and assuredly the time for legislation has fully come; for great as is the impulse which these statutes have given to the commercial development of the country, it is only too patent that they have opened the door to enormous abuses. Unscrupulous promoters have plundered the public, and not less unscrupulous wreckers have plundered the Companies, until between the Company-producer and the Company-consumer, it might almost seem as if a new industry had been created, having for its special object the destruction of all other industries whatsoever. It is high time that a remedy should be applied to this crying evil, and no class of society is more directly interested than are our readers in its being done, and done soon. The medical man who is laying by for the period of repose to which every hard-working man is entitled to look forward, can find no better investment for his savings than a well-managed and sound industrial company. As a rule, he is a fairly shrewd investor, but no acumen can make him safe from the depredations of knaves whom a defective law furnishes with the means of power of mischief, and protects from condign punishment. Is it too much to ask that these anomalies should be redressed, and that the law should be armed for the effective punishment of wrong-doers of this class? Surely we may fairly

ask to be defended from the swindler as we are already defended from the burglar and the bully.

THE *Hospital* reports and justly comments upon a marvellous and mischievous misstatement, or rather a series of misstatements, by which, it alleges, a City Company was induced to send "a very large grant" to one of "the metropolitan hospitals." The statements (by the mover of the grant) as given by our contemporary, were much as follows:—"That Hospital Sunday was everywhere a failure, because it not only lessened the aggregate amount of the income received by hospitals as a whole, but it destroyed the source of income. People who formerly gave pounds now give pence, or more probably 'buttons only,' through the offertory; and, finally, that so serious was this injury to hospitals, that the late Dr. WAKLEY expressed the deepest regret that he had ever been associated with Hospital Sunday." It is devoutly to be hoped, for their own sakes, that the City Companies are treated to more accurate statements in general, and that their liberal gifts are extracted by sounder arguments than these. Our contemporary has well disposed of the statement that Hospital Sunday has resulted in a loss to the hospital revenues. On the contrary, there is a clear gain to them of £20,000 per annum, on comparing the receipts of 1885 with those of the year preceding the institution of Hospital Sunday. At a very recent meeting of the Hospital Sunday Fund, the treasurer of the London Hospital and the treasurer of another metropolitan hospital explicitly stated that they had lost no subscriptions by Hospital Sunday. The London Hospital alone—that light in the dark end of London—has received in the last thirteen years from the Hospital Sunday Fund £40,742, and, according to its treasurer, this is all money to the good. We do not believe in the "buttons" theory much. The man who in a church would put buttons into a hospital collection is exceptionally mean and base, and must be a rare exception; and it is certain that the appeals and personal efforts of the ministers of religion have stimulated the erstwhile latent charity of many thoughtless and unimaginative people, who till then never considered what a hospital and its ministrations did for the sick who "cannot recompense" those who benefit them. It is possible and even true that some of the "Dispensaries" do not receive from the Fund all that they received from the collections of local churches. But this is a small set-off against a great movement, and one that should be easily corrected by local charity. But we have to make stronger protests still against this misleader of City Companies and other liberal bodies. His assertion that the late Dr. WAKLEY regretted his association with Hospital Sunday is one of the worst forms of misrepresentation that we can imagine, both as regards the deceased and the institution which he was the means of establishing in London, and which in the sufferings of his last days he cherished and supported so warmly. We have no idea which hospital is referred to, nor do we know the name of the City Company, but, assuming the accuracy of the report, it would have been more creditable to the orator if he had urged himself and his audience to a personal imitation of Dr. WAKLEY'S example, instead of misrepresenting his deepest sentiments, and on this misrepresentation founding an appeal for a hospital which is described in the pages of a journal specially devoted to the material interests of medical charities as one of the "least well-managed" hospitals. We may add that the late Dr. WAKLEY has bequeathed by his will, in addition to his former gifts, £1000 to the Metropolitan Hospital Sunday Fund.

Annotations.

"Ne quid nimis."

ARMY MEDICAL SERVICE.

As the groundless alarm on the subject of relative rank has been set at rest, it may not be amiss again to bring to the notice of the War Minister a real and substantial grievance seriously affecting a considerable, and yearly increasing, number of the medical officers of the Army. We allude to the date of their commissions on entering the Service. Prior to 1877 the commissions of all the officers who passed through Netley were dated from the day on which they joined the Army Medical School. In that year, however, a change was made, and has since continued in operation, by which the commissions of Army medical officers are dated from the completion of the course of instruction, while those of the surgeons for the Indian Service continue to bear the date of its commencement. The Naval candidates, who were withdrawn from Netley, enjoy the same privilege as the Indians, their appointments dating from the period of their joining at Haslar. The practical result of this system is that the Army medical officers must always—at least, until selected for administration rank—be the juniors of the Indian and Naval medical officers who pass the competitive examination at the same time with them, and who have no recognisable claim which would justify their being placed over the heads of their fellow-competitors. We do not know upon what grounds this invidious distinction has been made, but in our opinion it is a most incomprehensible act of injustice. It cannot fail to have an injurious influence upon the supply of candidates for the department, and, unless it is remedied, will create a marked difficulty in procuring a desirable class of candidates for the Army Medical Service. We trust that Sir Thomas Crawford will press upon the attention of the War Office the claims of his officers to have this grievance redressed, and that the War Minister will take an early opportunity of altering a regulation which acts so unjustly upon a meritorious class of officers. We can scarcely doubt that it will only be necessary to bring the case under his consideration to ensure the placing of candidates for the Army Medical Service upon a footing of equality with those who enter the other branches of the public Service under precisely similar conditions as regards competition and qualifications.

THE SANITARY CONDITION OF NEW WINDSOR.

A MEETING of the Urban Sanitary Authority of Windsor was held last week, and the sanitary administration of the town naturally occupied the attention of the Council. An important step was taken in the adoption of the report of a committee recommending the appointment of an inspector of nuisances. The Council are to be congratulated on the promptitude with which they have carried out the advice on this point of the Local Government Board's inspectors. By systematic house-to-house inspection much can be done for the maintenance of the town in better sanitary condition; the more serious improvements will doubtless be undertaken after a conference which is to be held between the Authority and the owners of property mentioned

Digitized by Google

in the report of the Local Government Board. Already letters have been exchanged between the clerks of the Sanitary Authority and of the Board of Guardians with reference to the erection of a hospital for infectious disease and for the provision of a disinfecting chamber. A proposal appears to have been made to erect in the first instance an administrative block only, and then, as stated by a member of the Council, "if a disease broke out, a temporary erection could be put up in which the patients could be treated." It is to be hoped this course will not be pursued, for it is quite obvious that the authority would then be deprived of the opportunity for the immediate isolation of cases of infectious disease. While temporary accommodation was being prepared it is likely enough the disease would spread and the town would probably have to bear the expenses of a more serious outbreak for want of means for isolating the first cases. A temporary hospital is moreover in the end, more costly than a permanent building. The experience of the Metropolitan Asylums Board and of many hospital-providing boards throughout the country has shown this, and Windsor would be acting more wisely in providing for immediate use, whenever occasion occurred, accommodation for the isolation of any infectious cases which could not with safety be treated in their own homes. The last recommendation of the inspectors—the erection of a furnace for the destruction of house refuse—has been referred to the Street Committee for their consideration. An interesting report by Dr. Casey, the medical officer of health, on the sanitary condition of Windsor during 1886, was presented at the same meeting. The report is mostly of a statistical nature. It contains no description of the more insanitary parts of the town, probably because the Authority are already in possession of much information on this subject. The report states, however, that "one house was condemned as unfit for human habitation." It may be hoped that Torrens' Act will be more freely used in the future than in the past.

ABDOMINAL SECTION STATISTICS IN KIEFF.

PROFESSOR REIN of Kieff, in a paper read at the recent Moscow Congress, gave the results of the ninety-five cases in which he had performed abdominal section from 1883 to 1886. Of these, sixty were ovariotomies with four deaths, twelve were for removal of large cysts of the broad ligaments with one death, fourteen for myomata with three deaths. The remaining nine—viz., three exploratory incisions, one enucleation of a cyst in the broad ligament, one section of a purulent abdominal cavity, one section of a purulent cavity in the pelvis, one castration (*kholoshchenie*), one ovariotomy with excision of cancerous omentum, one removal of an echinococcus of the omentum—gave three deaths. The causes of the eleven deaths are thus stated:—Purulent peritonitis, four; gangrene of the pedicle, one; gangrene of the remaining part of the tumour, one; erysipelas of the leg, one; exhaustion, one; effusion of blood into the pelvis and acute nephritis, one; sepsis, one; and carbolic-acid poisoning during the operation, one. The general percentage of fatal cases was therefore 11·5. Professor Rein remarks that he has tabulated every case he had without making any exceptions, though two or three of the patients were almost moribund when the operation was performed. The arrangements of the hospital wards, too, were far from being satisfactory. Regarding the operations themselves, some difficulty is usually experienced with the subperitoneal or connective-tissue cysts. He, however, had always succeeded in getting them away entire, enucleating them from under the peritoneum, or cutting them out from the broad ligament. He does not agree with Schroeder's plan of washing to prevent hæmorrhage, but recommends instead the ligature of the ovarian and uterine arteries. He practised drainage in nine cases, using indiarubber tubes passing through the vagina in three and glass tubes passing through the abdominal wall in the other six. These glass tubes are twelve millimetres in diameter, and are shaped like a tracheotomy tube. The later operations show a decidedly lower mortality than the earlier, owing to various improvements which have been made in the wards rendering them less septic. Though Professor Rein recognises the importance of antiseptic measures, he is quite alive to their possible dangers. Latterly he has contented himself with disinfecting the room, instruments, air, and operator's hands, not applying any disinfectant directly to the surface of the wound, and not irrigating it. The instruments and operator's hands were washed in simple boiled or sterilised water.

UNIVERSITY OF CAMBRIDGE.

AN important report has just been presented by the Special Board for Medicine to the Vice-Chancellor of the University of Cambridge for communication to the Senate. It recommends that the period of study necessary for the M.B. degree be made in all cases five years, the exception hitherto existing in favour of Honours students being done away with. The examination in pharmacy and pharmaceutical chemistry, forming part of the second examination, has for some time, it appears, been unsatisfactory; and though the Board has on several occasions revised the schedule issued by them for the guidance of students, the reports of the examiners show that a considerable number of the candidates are imperfectly prepared, and fail to grasp the particular application of chemical principles which the subject involves. The Board now recommends that the student should, during the earlier part of his course, have his attention directed to the chemical aspect of the materia medica, the parts of the subject relating to the dispensing and prescribing of medicines being studied at a later stage in immediate connexion with therapeutics and clinical medicine. They propose to indicate this change by altering the title of the examination to pharmaceutical chemistry, and by making the examination itself mainly practical; while the practical study of pharmacy or dispensing may be deferred until the student is attending hospital practice. The regulations for the degrees of M.B. and B.C. are to be so modified as to ensure every person who is admitted to either degree being fully qualified in both branches of practice. Certain other minor changes are recommended, and should the report be approved by the Senate, of which there can be no doubt, the new regulations will come into force at the beginning of the ensuing academical year, October, 1887.

THE USE OF UNCOOKED MILK.

THE question of the habitual use of uncooked milk which prevails in this kingdom is one which demands serious attention. Again and again have milk epidemics of typhoid fever, scarlet fever, and diphtheria shown conclusively how severely the incidence of the disease in question has been felt upon those using uncooked milk, as opposed to those taking milk only after it has been boiled or otherwise cooked. At one time it was thought that the matter involved only the question of the cleanliness of the dairy, and the freedom of those engaged in its management from communicable disease; and the mere fact of milk coming from country dairies has been held to be a sufficient guarantee of its wholesomeness. As a matter of fact, our experience goes to show that the danger is at its greatest according as dairies are situated in the more remote and rural localities; for it is precisely in scattered rural areas that first cases of ill-defined sore-throat and other affections in the families of those having to do with cows and milk are most

Digitized by Google

likely to pass unnoticed. But recent experience has shown that disease in the human subject, whether unrecognised or concealed, is not the only—perhaps not the greatest—danger that has to be contended with in connexion with our milk services. It has now been shown that the cow herself may suffer from a disease which at present is rarely, if ever, regarded as of any importance by dairymen, and which may give to the milk, at the actual moment of entering the pail, the power of producing scarlet fever in those who consume it in its raw state. Just as the excellent arrangements which have been made for the medical supervision of dairies must at times fail to detect certain cases of disease in the human subject, so must any veterinary or other inspection of cows fail in certain cases to prevent scarlatina-producing milk from being despatched from the dairy. We would therefore once again urge the importance of using milk only after it has been boiled or otherwise cooked. And for those who have not habituated themselves to the somewhat altered taste of boiled milk as a beverage, we may note that if milk be boiled immediately after its delivery by the milkman and be then set aside in a cool place for some six hours, the taste which is sometimes objected to will be found to be almost entirely removed; and not only so, but milk so treated keeps good and wholesome for a longer period than does unboiled milk.

MICROCOCCUS PYOGENES AUREUS.

MM. GABRIEL, ROUX, and LEPINE presented to the Société des Sciences Médicales, at a recent meeting, a series of tubes enclosing cultivations of the M. pyogenes aureus, modified by the action of acetanilide. If a mixture of equal parts of agar-agar solution and a watery 1 per cent. solution of acetanilide be inoculated with a dose of M. pyogenes aureus taken from a normal cultivation, the development may be carried out as usual in a stove at a temperature of 35·6° C. The area formed by the growing colony is, however, less compact, less thick, more flocculent, and, what is more interesting, does not assume the yellow orange tint after growing for from twenty-four to thirty-six hours, but remains dirty white, and preserves this tint; but a particle of this cultivation transferred to ordinary agar gelatine grows into a colony which regains the ordinary characters and colouration of the micro-organism.

WORRY NOT WORK.

THERE is nothing new in the dictum that "It is not work that kills men, it is worry." This has been said, and in nearly the same words, scores of times previously, by most writers on the subject. Nor is the remark "Work is healthy—you can hardly put more upon a man than he can bear," original; but Ward Beecher puts the facts forcibly when he says "Worry is rust upon the blade," except that rust commonly accrues upon inaction, whereas there is not a little worry associated with work, although the two things are quite different. "It is not the revolutions that destroy the machinery, but the friction." This is the truth absolutely. Work is not only harmless, but beneficial, because it stimulates the organism to recuperate. Worry exhausts not only the power which nature sets apart for action, but the vital strength upon which depends the replenishing of this power; and so by living at high pressure, which means a worried and anxious life, we both spend interest and eat up capital, with the result that nothing less than beggary stares us in the face, and all because we will haste to be rich, or famous, or great, or in some way prosperous. It would be well worth while to endeavour to teach people to take things easily, and remember that most of the very best things of life, whether of mind, body, or estate, are those which come only to those who can wait, and are not to be had at all for "pushing," "hurrying," or "struggling." How directly and practically it is true, as a maxim of life, that *patience* is the highest virtue, none know better than those whose business it is to keep a ceaseless watch on the course of life, and to be ever ready with head and hand to aid and smooth its progress from the beginning to the ending.

PHYSIOLOGICAL ACTION OF COCAINE.

DR. FREIBERG, working under Dr. Blumenthal, at Kowno, Russia, has arrived at the following conclusions respecting the physiological action of cocaine (*Berl. Klin. Woch.*, No. 10). Cocaine is a powerful anæsthetic, its action being limited to the surface in its immediate neighbourhood; and when brought into contact with an exposed nerve the anæsthesia is distributed over the periphery, but the central end of the nerve and motility are unaffected. In doses of half a grain to a grain in rabbits, and rather more in dogs, cocaine causes anæsthesia of the cornea, dilatation of pupils, retraction of eyelids, and exophthalmos; tonic and clonic spasms may occur, with loss of consciousness, and often fatal issue. The epileptiform spasms are doubtless of cortical origin. A difference as to the anæsthesia is observed between dogs and rabbits when cocaine is applied to nerve trunks. In dogs reflexes are abolished; in rabbits they are increased. Cocaine has a special affinity for the sensory and terminal sensory fibres of the cortex cerebri, whose function it inhibits. The disturbance of coördination may be attributed to interrupted conduction in the sensory fibres, both central and peripheral; and the convulsions, which are the main cause of death in cocaine poisoning, are due to the vaso-motor spasm and anæmia of the cortex. Bromide of potassium and the application of cold to the surface counteract this tendency; but with the first appearance of symptoms of cerebral anæmia, these toxic effects of cocaine may be mitigated or banished by nitrite of amyl.

CRIMINAL ABORTION.

AN inquest was opened at Islington by Dr. Danford Thomas on Feb. 28th last, and concluded a week later, touching the death of Catherine Tupner, aged thirty-five years. The deceased woman was married and the mother of five children. She aborted on Feb. 12th, and on the following day Mr. Wickers was called in to attend her. She died on Feb. 22nd. A death certificate of "puerperal metritis" was given and registered, but, from information received that foul play was suspected, the coroner ordered an inquiry. At the post-mortem examination it was found that the abortion had been induced by operative measures. There were no wounds of the vulva, vagina, or os uteri; but in the cervix uteri were several deep elongated lacerations, extending for nearly the whole length of the canal. These lacerations tapered off at each end. The body of the uterus, which was uninjured and empty of the products of conception, save for portions of the uterine part of the placenta, showed pregnancy to have advanced for fully three months. The peritoneum was acutely inflamed, especially in the pelvis. On the left of the uterus there was extensive cellulitis and abscess formation. There was suppurative pia arachnitis over the anterior two-thirds of the upper surface of the brain. The spleen was pultaceous and enormously enlarged. In the left kidney was a hæmorrhagic infarct occupying a quarter of its substance. The liver was large and fatty, the result of pyrexia and blood poisoning. There were thus the local and general effects of septic inflammation developed to a marked degree. In the right ovary was a corpus luteum fully half an inch in diameter, consisting of a large black central blood clot and a peripheral corrugated zone of orange-coloured tissue. In the same ovary was a minute stellate cicatrix, the remains of a ruptured follicle due to a past menstruation or conception. In the left ovary was a cyst a quarter of an inch in diameter containing sepia-like fluid. These facts

Digitized by Google

relating to the ovaries are interesting, inasmuch as it is said the pregnancy was a twin one. It appears, then, that either both ova were liberated from the same follicle, or else the second corpus luteum failed to develop. Now, considering the extent of the lacerations of the cervix, and that the parts external to it were free from wounds, the opinion formed by the medical men consulted that the operation had been performed by a practised hand was well grounded. Clearly the deceased could not have inflicted the injuries herself, and it is scarcely possible that a person wholly unskilled in instrumentation of the uterus could have avoided wounding the vagina and os uteri. The jury returned a verdict of "Wilful murder against some person or persons unknown."

SIR JAMES PAGET ON THE DENTAL HOSPITAL.

THE efforts which were made this year to render the annual dinner of the Dental Hospital of London a success were amply rewarded. Sir James Paget took the chair, and amongst the guests were many eminent members of the medical profession, and all those present showed the greatest sympathy with the object of the meeting—namely, to create an interest in the good work done by the Dental Hospital, and to appeal to the general public for subscriptions to enable the premises to be extended, since they are quite inadequate to the increasing number of patients. Sir James Paget, in proposing the toast of the evening, observed:—

"It was difficult to estimate, for example, the amount of happiness which was given to the 40,000 people who had been attended in one year. This total was still increasing, and had increased, he believed, 4000 within the last month. Few persons had passed through life without knowing the happiness of good dental surgery. Let them imagine 40,000 people suffering without any hope of remedy. They might consider the comfort we had from the teeth. That very evening a great part of their enjoyment of a good dinner had been due to them. On the morrow their comfort would be in some way determined by the way in which their teeth had been judiciously employed. If they multiplied their pleasure by 40,000, they would estimate more nearly the benefits conferred by the institution. Besides, they were aware of the influence of the teeth on the general health. There they stood—the boundary between that which was dead and that which was to be living,—and upon them depended the first and often the principal step of what should be the progress in the change of the dead into the living by the process of digestion, and what the value of the living texture should be which had begun to form. Here the amount of good which they did was past measurement. The Dental Hospital was, as far as he knew, the best institution of the kind which was to be found in Europe, if not in the whole world."

SCHEDE'S METHOD OF DRESSING WOUNDS.

PROFESSOR MIKULICZ communicates to the *Przeglad Lekarski* an account of fifty cases of surgical operations which were treated by the method recommended by Dr. Schede at the last surgical congress in Berlin—viz., to allow blood to fill the wound and to lie between the lips after they are brought together, any deficiency in the quantity of blood being remedied by the use of the knife, the idea being that the blood either actually becomes organised or serves as a protection for the granulations as they are formed. The wound is covered with protective, to prevent evaporation. Professor Mikulicz's observations included six resections of joints, four amputations, six dissections, two ligatures of arteries, seven extirpations of large tumours, &c. In thirty-six of the fifty cases union took place without suppuration, in four there was extensive formation of pus, in five superficial suppuration starting from the points of suture, and in the remaining cases pus had existed previously to the operation, and the disinfection at the time not having been complete, it continued subsequently. The general condition of the patients was highly satisfactory, even in those cases where suppuration occurred, the temperature in no case rising much beyond normal. The dressings were not removed or changed for at least a fortnight, sometimes not for a month. This appears to be of great advantage in the case of bone and joint operations, where complete immobility of the parts is a desideratum. Other specified advantages attributed to this plan are that wounds attended with a loss of substance rapidly fill up, and the cicatrices that form are peculiarly soft and smooth. Professor Mikulicz does not find, as Schede did, that the existence of silver sutures in osseous lesions has any unfavourable influence on the cicatrisation of the wound. He remarks that it is important not to bind the external dressings too tightly to the wound.

THE VICTORIA UNIVERSITY.

A NUMEROUS deputation waited upon the Chancellor of the Exchequer, at the Foreign Office, on the 11th inst., to lay before him the claims of the Victoria University to an annual grant from the national exchequer in aid of the expenses of examinations for degrees, memorials in support of which had been adopted by a large number of public bodies in Lancashire and Yorkshire. The deputation, which was introduced by the Marquis of Hartington, urged that the Victoria University had exercised a beneficial effect on the general education of the district; that the future annual expenditure of the University was estimated at about £2500; and that it will be seriously impeded in its progress, and prejudiced in its usefulness as a centre of higher education, unless its resources can be supplemented by a grant from the public funds. Mr. Goschen undertook to give the matter his consideration, and to bring it before his colleagues, and stated that the consideration he would give it would be, if he might use the phrase, a benevolent consideration. The deputation then withdrew.

THE INTERNATIONAL STATISTICAL INSTITUTE.

THE next Congress of this Association will be held in Rome on the 12th proximo, and the preparations already on foot for the reception and entertainment of its members give promise of a brilliant gathering. Its president will be our countryman, Sir Rawson W. Rawson, and the programme just issued under his name is varied and interesting. The noble palazzo of the Ministry of Finance will be placed at the disposal of the Institute by his Excellency Signor Maghiani, Chancellor of the Exchequer; while Government and Municipality will vie with each other in making the sojourn of their guests both pleasant and profitable. In April the Roman spring is in its most enjoyable phase, whether for sight-seeing in the city or for excursions beyond the walls, and the high standard of health maintained throughout the winter is not likely to be lowered by steadier and more genial weather. In the various sections there is a rich fund of topics of medical interest, in which the voice of the profession will make itself heard through some of its most authoritative representatives. Sir Rawson's opening address will be followed by the arrangement of proceedings and other business formalities, and then the Congress will settle down to work on "Census Statistics—the differences which exist in the published results of different censuses, and proposals for arriving at the means of an international comparison" (reporter, M. Joseph Körösi); on "Social Statistics—the best method of measuring the social and economic condition of a country at any particular period" (reporter,

Digitized by Google

Professor von Neumann-Spallard); on "Economic Statistics—budgets of family expenses, as to the measure of the well-being of individuals, families, and nations" (reporter, Dr. Ernst Engel); and on "Vital Statistics—report on the fecundity of marriages, by M. A. N. Kiœr, in continuation of the report which he presented to the Statistical Society of Paris at its twenty-fifth anniversary." Other sections in which the reporters are such well-known statisticians as Mr. Robert Giffen, Major P. G. Craigie, M. Emile Levasseur, Dr. von Inama-Sternegg, and M. A. de Foville, will further enhance the interest of the discussions; and after the place and time of holding the next Congress of the Institute has been agreed upon, the proceedings will close on the 16th prox. Those of the profession who intend to assist at the approaching Congress with special contributions of their own or of their friends are requested to intimate the same to the President, Sir Rawson W. Rawson, at his London address, 68, Cornwall-gardens, S.W., before the 31st inst.

THE FACULTY OF NANCY ON THE ASSISTANT PROFESSORIATE (AGRÉGATION).

THE Nancy Faculty of Medicine having deputed MM. Hecht, Bernheim, and Heydenreich to examine into the regulations for the competition for the grade of *agrégé*, or assistant professor, and into those concerning the subsequent employment of the fortunate candidates, this committee has just published a report on the subject in the *Revue Médicale de l'Est*. This report recommends that, considering the difficulties of obtaining the coveted grade, the tenure of the position should be extended from the nine years, which is its present duration, to fifteen years, at all events in the provincial faculties. This would tend to assure most of the *agrégés* of ultimate appointments to professorships. The report also suggests some alterations in the examination for *agrégation*—namely, the omission of the essay on an anatomical or physiological subject, and of the thesis and disputation on it: the judgment of the jury being instead based upon (1) the previous record and works of the candidates; and (2) a lecture of three-quarters of an hour, similar to that which is now required, but giving the candidate the choice of three subjects, instead of confining him to one as at present. No opinion is expressed on the locality of the examinations. At present they are always held in Paris, and complaints are sometimes heard that provincial candidates are at a considerable disadvantage in comparison with those who have studied in Paris.

SCHOOL HYGIENE.

A CORRESPONDENT sends us his own experience of the sanitary condition of private schools, which is no doubt shared by others who have directed attention to this subject. He sent his son to a private day school where the drainage and ventilation were defective, and an attack of gastric fever resulted in his removal to another school, where again the house was not free from unwholesome smells. A complaint to the schoolmaster was met with the request that the boy should be withdrawn. A third school was found, but this had the important disadvantage of being so constructed that the pupils were required to work in shadow while they faced the full glare of windows. Our correspondent pleads for some proper control over these institutions; the matter is indeed very much in his own hands and those of other parents. If schoolmasters found that the guardians of children required satisfactory evidence of the hygienic condition of the schools to which they propose to send their children, there is but little doubt the necessary improvements would be effected. It is not probable the Legislature would consider that school-houses should be dealt with differently from dwelling-houses; nor, indeed, if sanitary authorities were endowed with special powers for these institutions, can it be expected they would be adequately exercised. It is therefore desirable that efforts should be made to induce parents to recognise the importance to their children of health conditions, and we might suggest that schoolmasters would be consulting their own interests in meeting the reasonable requirements of those who entrust their children to their care.

CONDITIONS OF SUCCESSFUL PRODUCTION OF LOCAL ANÆSTHESIA IN TOOTH EXTRACTION.

DR. A. LEBRUN of Brussels and his house-surgeon, M. Andries, have published the notes of twenty-nine cases in which they employed local cocaine anæsthesia for the extraction of teeth. In twenty-three cases the anæsthesia was complete, in one case partial. In the remaining five cases the procedure was unsuccessful. This is attributed by them to the difficulty of introducing the short straight needle of the ordinary hypodermic syringe in the case of the second and third molars, and also perhaps to no precautions having been taken to prevent the escape of the liquid. They point out that M. Viau of Paris, who succeeded in producing complete anæsthesia in every one of his eighty-six cases, made use of a specially constructed syringe, with a holder by which it could be grasped firmly between the index and middle fingers, and provided with needles of various degrees of curvature; also that he surrounded the tooth with plugs of cotton-wool, and applied the finger over the puncture after the withdrawal of the needle. Besides which he made the patient keep rinsing his mouth with cold water during the five minutes that intervened between the introduction of the cocaine and the actual operation. These precautions were not observed by MM. Lebrun and Andries. They used, however, a solution similar to that of M. Viau—viz., fifty centigrammes (seven and a half minims) of a 2 per cent. solution of carbolic acid containing five centigrammes (three-fourths of a grain) of hydrochlorate of cocaine, half of which quantity was injected into each surface of the gum.

THE TEACHING UNIVERSITY MOVEMENT.

THE Councils of University and King's Colleges have arranged to act conjointly in the movement for promoting a new university in London. They have accordingly addressed letters to the Presidents of the Royal Colleges of Physicians and Surgeons offering to join the Councils of those bodies in promoting a joint charter for the proposed new university in London, in which the Faculties of Arts and Science would be formed by University and King's Colleges, and that of Medicine by the Royal Colleges. If this proposal be favourably entertained, the movement will satisfy those who wish for an academical status, as well as those who only ask for a purely professional degree.

THE GENESIS OF ELASTIC FIBRES.

DR. SERGIO PANSINI of Naples publishes the results of his researches into the origin of the elastic fibres of connective tissue and elastic organs in *Il Progresso Medico* of January and February last, as follows:—1. Elastic fibres, large and small, have a cellular origin, derived from cellular elements, which, on account of the transformations they undergo, may be considered as having special characters. 2. The process of transformation consists in the elongation of the cellular elements, first of the protoplasm, afterwards of the nucleus. 3. The process of transformation begins in the protoplasm, and is continued by the nucleus, which on this account has an important histogenetic value. 4. Once formed, the elastic fibre is solid, not hollow. 5. The granular appearance shown by all elastic fibres is not an indication

Digitized by Google

of the origin of these fibres by fusion of the granules of a fundamental substance, but is due to the arrangement of the integral substance of the fibres. 6. Elastic fibres in the ligamentum nuchæ are not united by simple cementing substance, but by a connective network, which embraces each individual fibre in its meshes. In thickened portions of this connective tissue the arteries and veins ramify, and also by its means the plasmic juices are distributed in organs poorly supplied with vessels.

GUY'S HOSPITAL.

"AN Inquirer" in the *Daily Chronicle*, who has not the courage to put his name to his letter, suggests extravagance in the administration of Guy's Hospital, as in sums spent in the treasurer's house and in highly paid local stewards on each estate. We need not say how easy it is to stop the flow of charity and to insinuate extravagance, where probably none exists. To do this to an institution like Guy's suffering acutely from the depression of the times, is not a creditable achievement. We do not pretend to know much about the details of the administration of Guy's, and we think it quite possible that the authorities would act wisely in taking the public a little more into their confidence. But we are able to say that the suggestions of the letter are most inaccurate and unfair to the hospital. It is not the case, as suggested, that the sum of over £5000 was spent on the treasurer's house when rents were greatly falling; only £2000 were spent on the house and furniture, and that when the treasurer came into office in 1876, and as a condition of his doing so, nothing having been done to it for twenty-seven years prior to that time. When these necessary repairs were made the hospital was in prosperous circumstances and saving money. It is not true, as implied, that the treasurer is a "highly-paid" official. He is an unpaid officer, but has a furnished house, on which no money has been expended for eleven years. The management of the estates is a matter on which opinions may differ. They consist, we believe, of 50,000 acres, chiefly in Herefordshire and Lincolnshire. There is a land steward in each case. One has a house only, and the other is paid a commission on the rents. We have said enough to make anonymous critics of great charities a little more careful in pursuing their easy but unwise calling.

RESEARCHES ON THE REFRACTION OF THE EYE IN STOCKHOLM.

PROFESSOR JOHANN WIDMARK has recently concluded a long series of researches upon the state of the refraction of the eye in the schools of Stockholm, and he has had the opportunity of examining 704 males and 742 females. The results he obtained were as follows: In the first schools, comprising children from six to seven years of age, there was no myope. In the second set of schools, comprising girls from eight to nine years of age, there was only one myope. In the corresponding school for boys the myopes had risen to 14 per cent. This difference is probably due to the fact that the boys have to undergo a special examination for entrance into the first class of the secondary schools, and are consequently compelled to work harder in the preparatory school. At the age of sixteen, when female education usually ceases in Swedish schools, 33 per cent. of the girls were myopic, the mean amount of myopia being −2·5 D, which was about equal to that of the boys at the corresponding age. In the higher schools the girls proved to be more frequently and more highly myopic than the boys, the proportion being 54·28 per cent. with an average of −3·3 D, although the girls' schools took from one to two years' more time over the same subjects. The maximum frequency of myopia, 66·67 per cent., occurred in a girls' school, and the maximum amount of myopia, −4·16 D, also occurred in a girls' school, which seems to show that an excess of work for the eye is more injurious to girls than to boys. This depends in part perhaps upon the greater feebleness of the girl as compared with the boy, but it is in part due to the fact that in leisure hours the girl occupies herself with handiwork requiring close attention, and with music. Moreover, the means of physical education are very inferior in schools for girls, and gymnastic exercises are either not at all or very insufficiently practised.

AFTER-EFFECTS OF THE EARTHQUAKES ON THE NERVOUS SYSTEM.

IT is curious to note that many persons who were calm and apparently not greatly disturbed by the earthquakes which recently occurred in the Riviera have since suffered seriously from the effects of shock. This fact shows beyond the possibility of question that more may be done in the way of injury to the nerves by an undue excitement than is at the time perceived, just as more may be done in the way of restoration to nervous health after an illness than is immediately evident. The explanation of these seemingly paradoxical effects is to be found in the fact—perfectly familiar to every student of nerve-troubles—that in a very special manner health in respect to the nervous system is dependent upon the integrity or orderly performance of nutritive functions. Muscular tissue may be badly nourished for a time, as in the course of an ordinary illness, and as soon as convalescence is fairly established recovery of the wasted muscles will commence, use stimulating re-growth naturally, with the result of perfect recovery in a comparatively short time. It is not thus with nervous tissue, whether in brain, spinal cord, or nerve trunk. When from any cause nutrition is impaired in a nerve centre or branch, not only is there extraordinary difficulty in restoring the integrity of nervous function, but the wear and tear of ordinary life, even when these are reduced to a minimum, seem to increase the exhaustion instead of reducing it by stimulation of the recuperative faculty. The reason of this seems to be that nerve centres, like batteries, are apt to be discharged suddenly and sometimes unconsciously; and when once what may be termed the residual stock of energy is consumed, it takes a very long time and often extreme carefulness to restore this reserve. Until the loss of strength held in reserve is slowly accumulated by an excess of production over consumption, the nervous system is, so to say, working on its daily strength, and can have none of that buoyancy which is due to the existence of a stock of force which has been unexhausted. No doubt those present in the earthquakes, though calm, were subjected to a severe strain, and they have not yet had time to recuperate.

LIABILITY OF AGENTS FOR MEDICAL CHARGES.

THE County Court judge at St. Helens, trying an action by Dr. Edward Casey to recover £14 12*s.* for attendance on four men from the Collin's-green Colliery Company, said that the manager of a company might send for a medical man on grounds of humanity without thinking that he incurred liability. The claim of the plaintiff was based on the fact that he had been sent for by the manager on the occurrence of an explosion by which the men were injured. The charge was for one day's attendance and operations. The particulars are not given, and we cannot pretend to judge of the reasonableness of the charges. But the judge's doctrine is one to which we cannot assent. The manager of a company is a responsible agent, and must be held so when he sends for medical men. It is very easy to be humane at the expense of the medical profession, but there has been too much of this kind of humanity. The judge gave judgment against the manager for three guineas, and laid down that

Digitized by Google

he company were not liable. The manager had himself offered £10 in settlement, but this had been declined by the plaintiff, who obtained leave to appeal. We are glad of this, for the view taken by the judge is, as the counsel for the plaintiff said, one of serious import to the profession, and ought to be settled by higher authority.

"DEATH-TRAPS."

WE are glad to find that those wretched gratings which afford means of ventilating (!) the sewers on the street level in the great majority of our public thoroughfares are beginning to be regarded in their true character as "death-traps." Nothing but the most strange obtusity, or an inexplicably perverse ingenuity in the defence of a hopelessly condemned system, can account for the fact that there are still persons who speak with authority on the subject of sanitary engineering to be found saying smooth things of the street level ventilators and man-holes. There is something so grotesque in the notion of intentionally establishing any way of escape for the gases generated in sewers into the atmosphere at the levels where people walk that nothing but amazement can be excited by the re-utterance of all the silly things that have been said by the defenders of this system. There is only one rational remark to be made on that side of the question, and it is that it would cost a great deal of money to get rid of these surface ventilators and man-holes and to replace them by reasonably sanitary apparatus; for example, high ventilating shafts reaching above the level of uppermost rooms and chimneys. This is the very most that can be said in defence of the *status quo*. The reply is obvious. Nothing can be done to amend a condition of matters which is wholly indefensible without a large expenditure; but when we remember that lives are distinctly sacrificed to the evil genius of persistent blundering, it may well be concluded that it would be worth a good deal to put an end to the slaughter if only because we do not know *who* the next victim may be.

THE LONDON HOSPITAL.

WE regret to hear that there is a considerable amount of friction existing at present between the medical staff and students of the London Hospital. For some time there has been dissatisfaction felt, and partly expressed, by the students, but this recently culminated when one of the surgeons was openly hissed by a body of the students when about to visit his wards. The commencement of the difference would appear to have been the appointment to the new office—that of receiving-room officer—of a gentleman holding University degrees, but who had not gone through the full course at the hospital.

THE ETIOLOGY OF DYSENTERY.

IN a communication to the Bohemian Medical Society Professor Hlava gives an account of a number of observations he has made on the subject of the etiology of dysentery. He examined the stools and the bowels with their contents post mortem in sixty cases of epidemic dysentery, also in two cases of a sporadic nature, and in ten where the symptoms of dysentery were developed as complications of other diseases. He also injected the fresh stools of dysenteric patients into the rectum or duodenum in seventeen dogs, six cats, eight rabbits, hens, and porpoises, and made seventy cultivations of bacteria of various kinds found in dysenteric stools. The conclusion he arrived at was that bacteria are not the cause of dysentery, for none of the micro-organisms were reproduced in the animals experimented upon, only a transitory catarrh being found. No qualitative anatomical distinction could be made out between cases of epidemic and of sporadic origin. Professor Hlava investigated the amœbiform large-grained protoplasm which he found in the dejections in considerable quantity in sixty-five cases, and on the intestinal mucous membrane and in the submucous tissue in twenty cases. On putting these bodies under the microscope, he found that the amœboid movements continued for ten hours. He has commenced a series of observations on the effects of injecting them into the intestines of animals, with the object of showing that these bodies have a causal relation to the disease.

PRECAUTION AND PANIC.

ITALY must clear herself of the reproach that in face of an epidemic she has recourse to measures which the calmness begotten of forethought might have spared her. The reappearance of cholera at Catania, due to her neglect of the sanitary precautions suggested by its recent presence in other parts of Sicily, has made her impose in hot haste a five days' quarantine on all departures from Sicilian ports, so that to get from that island to the mainland one must steam from Palermo to Bastia in Corsica, and thence make the best of one's way to the Italian seaboard. Her better-inspired organs of opinion are denouncing this hygienically useless and commercially disastrous measure. "Notre politique sanitaire est déplorable," says the Roman *Italie*; but how is it to be helped when the deputies to the Corps Législatif yield to the clamour of their ignorant and panic-stricken constituents, who insist on imposing quarantine on their compatriots? The enlightenment of the masses, the deepening and elevating of their sense of citizenship, must in Italy precede much sanitary legislation which in England has long been the law of the land. Italian physicians, too, by their adhesion to quarantine and hygienic cordons, must cease to justify the superstitious laity in its reliance on such "precautions."

DEATH OF DR. CARRINGTON OF GUY'S.

WE regret to say that Guy's has sustained another misfortune in the death of Dr. Carrington. He was senior assistant-physician, and died on Wednesday morning from pleuro-pneumonia after two or three days' illness. On Sunday last he made an important post-mortem of a man who died from symptoms much resembling those of glanders, and it is thought that he may have become infected with some animal poison. This is the fourth physician which Guy's has lost in four years. We shall reserve any further notice of Dr. Carrington, only now remarking that in his death the profession loses one of its most popular members, who was as modest as he was promising.

"BLUE-STONE" AS A TOXIC AGENT.

A LABOURER was recently charged at the West Ham Police Court with attempting to commit suicide by taking sulphate of copper. From the evidence it appears that the accused went to a chemist's near his residence and purchased a pennyworth of "blue-stone." On being served, he put the drug in his mouth and commenced eating it. The chemist attempted to stop him, but the prisoner declared that he was tired of life and would do as he liked. In a few minutes, however, the sulphate of copper acted as an emetic, and the man was then given into custody. On being brought before the magistrate, he expressed regret at the occurrence, and was discharged with a caution. We do not know what quantity is usually supplied by chemists for a penny, but an ounce not infrequently gives rise to disagreeable symptoms, and might even be attended with a fatal termination. The best treatment would be to give eggs and milk freely, or arrowroot and barley-water, with a hypodermic injection of morphine to allay pain. It does not appear that in this case any large quantity was taken.

MYXŒDEMA.

THE Myxœdema Committee of the Clinical Society of London has completed its investigation of the etiology, symptoms, and morbid anatomy of this interesting disease, and it is now engaged in studying the question raised by Professor Kocher's observations of the effects of total extirpation of the thyroid gland. For this purpose Dr. Felix Semon has issued a letter to all surgeons who are known to have performed this operation, asking for a statement of the results observed. We are requested to state that it is very desirable to have this part of the committee's investigation as complete as possible, and it is hoped that all who can will return full and accurate replies to the questions given. If anyone who has information on this point does not receive a circular, he is requested to apply at once to Dr. Felix Semon, who will be pleased to furnish him with one. The circular contains an admirable account of the clinical features of the disease and a photograph of a typical case. We trust that the committee will meet with a hearty response to its request for facts, and that it will be enabled to furnish its report quickly.

CHOLERA IN SICILY.

CHOLERA continues at intervals to occur at Catania. From midnight on the 10th inst. to the morning of the 12th there were seven cases and one death. So far, the disease appears limited to this one town in the island of Sicily.

On this subject our correspondent at Rome writes, March 14th:—"Grave doubts having arisen in medical circles as to whether or to what extent the recent outbreak at Catania is choleraic in character, the Superior Council of Health has deputed thither a sanitary commission composed of Professors Albanesé of Palermo, De Renzi of Naples, and Marchiafava of Rome, to study and determine the nature of the disease."

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—Dr. Bonamy, Professor of Anatomy at Toulouse. Dr. Carl Heinrich Reclam, Professor of Hygiene and Medical Jurisprudence in Leipsic, and editor of *Gesundheit*, at the age of sixty-five. M. Emile Leudet, chief of the Preparatory Medical School at Rouen.

A NEW INHALER.

DR. COZZOLINO, lecturer on Laryngology &c. at the University of Naples, has introduced a very simple form of inhaler, consisting merely of a pair of metal tubes three-quarters of an inch in length connected by a curved band, which are inserted into the nostrils and can be worn for some time without discomfort and without attracting much attention. Within the tubes a bit of blotting-paper is placed, which is then saturated with whatever substance the patient is ordered to inhale; he must then inspire by the nose and expire by the mouth, and by this means will take the whole of whatever dose of volatile liquid the blotting-paper may contain.

DIRTY AND TROUBLESOME INCURABLES.

THESE classes of patients ought surely to be removed from asylums and provided for elsewhere, if asylums are to be expected to do curative work. Dr. Rorie insisted strongly on this reform in a paper read before the Medico-Psychological Association in Edinburgh, and we entirely agree with the opinion he expressed. If the non-dangerous classes can be accommodated in workhouses, those which only need supervision for the enforcement of cleanliness and the promotion of ordinary comfort ought to be disposed of in the same manner. As we have so often contended, if only it could be seen that *hospitals* for the insane would do infinitely more to reduce the proportion of persons attacked with mental disease who became hopelessly insane than *asylums* can possibly do, there would be not only a large economy of brain-power and sanity in the population as a whole, but a great saving of money to the ratepayers, to the general advantage and content.

MEDICAL HONOURS.

AT an investiture held by the Queen at Windsor Castle on the 14th inst., Sir George Christopher Molesworth Birdwood, who had been already knighted, was introduced into the presence of Her Majesty and invested with the insignia of his dignity in the Order of the Indian Empire. In like manner Surgeon Charles William Owen was introduced and received the badge of his dignity in the Most Distinguished Order of St. Michael and St. George. The following Companions of the Order of the Indian Empire also received their badges: Brigade Surgeon Henry Elmsley Busteed and Dr. Thomas Beath Christie.

GASTROTOMY IN ITALY.

THE *Gazetta degli Ospedali* of February 23rd gives the details of a gastrotomy performed by Professor Loreta of Bologna, on account of severe pain suffered by a young woman who had swallowed a large quantity of needles with the intention of committing suicide. On searching the stomach carefully with the hand, few needles could be found. The cause of the pain and suffering was explained by further search and extension of the abdominal incision to the right over the liver. The points of several needles were found protruding above the surface of the margin of the left lobe of the liver, and these were deemed to be the source of the pain. Some were withdrawn, but others were so fragile that they broke off. The wound in the stomach and the abdominal parietes was accurately sutured, and the patient recovered without a bad symptom, entirely freed from her suffering.

SUPERVISION OF SLAUGHTERHOUSES.

THE London Model Abattoir Society is doing excellent work in the interests of both humanity and public health. The atrocious cruelty of some of the men and boys employed in slaughterhouses, partly because they are brutal and partly because they are ignorant of their business, calls urgently for reform; while the perils to which health is exposed by the way in which meat is prepared for use as food are of a very alarming character. Better inspection is clearly necessary, and upon this need the Society, which has Dr. B. W. Richardson for its president, strongly insists.

INSTANT AND EASY DEATH FOR CRIMINALS.

IN so far as it is prudential to divest the death penalty of its ignominy and terror, it will be satisfactory to find the progress made in obedience to the dictates of humanity in searching for an instantaneous and easy death to supersede that by hanging. The Legislature of New York having appointed a committee to deal with this grim subject, the result is a recommendation to employ electricity. The whole question seems to us to be one of policy. If it be decided, first, that it is justifiable to take life at all, and, second, that the least appalling mode of execution is to be preferred, then there can be no question that electricity offers a promising mode of killing quickly and painlessly. On a recent occasion we commented with regret on what certainly appeared to us a too theatrical mode of execution.

Digitized by Google

It is most desirable to avoid casting a glamour of fascination about the death penalty. Is there not a peril of doing this in the impulse to be humane?

FOREIGN UNIVERSITY INTELLIGENCE.

Berlin.—The recent medical vacation classes have been well attended by foreign practitioners. Out of 148 there were seven from England and Scotland, thirteen from North America, thirteen from Sweden and Norway, six from Brazil, and two from Japan.

Buda-Pesth.—Dr. David Onodi has qualified as *privat docent* in Embryology.

Dorpat.—The Russian Ministry of War has arranged to give a grant of £250 to a laboratory and clinic that is about to be established in connexion with the Veterinary School for the express purpose of investigating the subject of glanders.

Gottingen.—Dr. Wolffhügel has been appointed Professor of Medical Chemistry and Hygiene, and Director of the Institute in connexion with these subjects in succession to Professor Flügge, who has gone to Breslau.

Leipsic.—Professor Heubner, who had at first accepted the invitation to the chair of Therapeutics at Prague, has, at the urgent solicitations of his friends, decided to stay in Leipsic.

AT a late meeting of the Hexham Board of Guardians the following resolution was proposed and carried: "That the medical officers of this Board be requested to discontinue as much as possible the use of intoxicating drink to the pauper patients of this union, and only to order its use in urgent cases." One of the guardians had the good sense to say it was a very delicate thing to interfere with a medical man's prescriptions for his patients, and another stated that the consumption of alcohol in the Hexham Union was much below the average of England. How little this absurd resolution was required at Hexham was pointed out by the master of the workhouse, who stated that there was now only one inmate, an old woman of ninety-five, receiving alcohol in the house. There are other matters, perhaps, to which the Hexham guardians might profitably devote their attention rather than medical prescriptions.

BY Lord Gifford's will, which was published on the 11th inst., it is proposed to found in each of the four Scotch Universities a Professorship of Natural Theology, the lecturers to be submitted to no test of any kind, to be of any denomination whatever, or of no denomination at all, and to be charged with the free discussion of all questions about God and the Infinite, their origin, nature, and truth. In case the Senatus Academicus of any university should be tempted to decline the munificent bequest in consequence of the condition with which it is accompanied, it is specially provided that the Faculties of Physicians and Surgeons, or of Advocates, may, if necessary, take the place of the university.

A WORK, by Dr. Alfred Carpenter, of interest to educationists and social reformers, entitled "The Principles and Practice of School Hygiene," will be issued next week by Mr. Joseph Hughes, of Pilgrim-street, Ludgate-hill. The book will be profusely illustrated, and will contain special chapters on the cure and prevention of disease in the family.

THE Gordon Boys' Home is to be commenced at once on a piece of ground near Bagshot, and is expected to cost £10,000. This estimate does not include a small hospital, which the committee consider necessary, and for which funds are wanted.

WE may remind intending candidates for the vacant posts of Examiners in Medicine and in Forensic Medicine in the University of London that their names must be sent in, with any attestations of qualifications they may deem desirable, on or before Tuesday, March 29th. Our note last week was inaccurate in stating that the former holders of the offices of Examiners in Medicine offered themselves for re-election, the appointments being actually as well as nominally vacant.

THE Bishop of Peterborough has lately made an excellent speech on Temperance, insisting that intemperance has many causes, and that moral and social remedies are of as much, if not more, consequence than legislative ones. He expressed the opinion that this country was more deficient in social and innocent amusements than any other, and that the sanitary condition of the people required careful consideration—views in which we heartily concur.

STATE MEDICINE in Italy has just lost an able and energetic representative in the Senator Angelo Grossi—a physician of high reputation as a consultant before his patriotic services secured his election to Parliament for his native Lombard constituency, and his further nomination as one of the "Patres Conscripti" of the new Italian kingdom.

ON Saturday last Dr. Waters was presented at Chester with a testimonial in the form of his portrait by Mr. Frank Holl, and a cheque for £296. The profession to which he belongs, and for which he has worked heartily, will be gratified by this latest tribute to him.

A SEVERE epidemic of measles has recently been raging in Norwich. Scarcely one point of the city has escaped infection, and the schools, both day and Sunday, in the neighbourhoods in which the disease has been most prevalent, have been closed.

WE are asked to state that the Jacob testimonial fund now amounts to a sum nearly approaching £500. The subscription list will close on Monday next. Professor E. Hamilton, 120, Stephen's-green, Dublin, is the hon. treasurer.

As the result of injuries received on the Great Western Railway a few days since, Mr. A. Ellis Eyton, L.R.C.P. Ed., L.F.P.S. Glas., lost his life. Mr. Eyton was forty-five years of age, and practised in Hammersmith.

THE objects of some sections of the Rivers Pollution Prevention Act of 1876 having been ascertained to be impracticable, Mr. Thorburn, M.P., has introduced a Bill to amend certain of the sections of the Act.

ARMY ESTIMATES.

THE army estimates for 1887-88 show a decrease under the head of "Medical Establishments and Services" of £9000. There is a reduction of £5980 in the pay of "medical staff," £3300 in "departmental and duty pay of medical staff corps, nurses, and miscellaneous labour," and £1100 in "cost of medicines," while there is an increase of £1280 in the pay of civilian medical practitioners. The *personnel* of the department, inclusive of the staff at headquarters, but exclusive of 335 officers employed in India, is estimated at: 1 Director-General, 8 Surgeons-General, 18 Deputy Surgeons-General, 559 Brigade-Surgeons, Surgeons-Major, and Surgeons, and 54 acting medical officers. The latter are officers on the retired list, who are employed in special appointments and receive £150 per annum, in addition to their retired pay.

Digitized by Google

The pay and allowances of the medical staff and of an average of 25 surgeons on probation at Netley amount to £254,720. The expenses of the Army Medical School at Netley are stated at £7641, but this includes £700 as the allowance to the examiners of candidates for admission to the service, and also an item of £200, which appears for the first time, under the head of "Allowance to Army Surgeons in Aid of Expenses incurred in obtaining Certificates in Operative Surgery." Deducting these two items, the sum required for the school amounts only to £6741. From the amount taken for surgeons on probation, the number of vacancies to be provided for in the department during the year appears to be estimated at 50. In addition to the charge for army medical officers, £6400 are wanted for the pay of civilian medical practitioners and medical bills, of which £6000 are for home and £400 for colonial services.

The retired pay for medical officers is estimated at £182,000, being £20,000 in excess of the preceding year, almost entirely due to an increase in the number of surgeons-major. There are at present only fourteen medical officers on half-pay who are eligible for employment. The usual amount of £1400 is taken for rewards to medical officers for distinguished or meritorious services.

The strength of the Army Hospital Corps is estimated at 2640 of all ranks, of whom 2080 are on the home and 560 on the colonial establishment. The amount taken for the regimental, departmental, and extra duty pay of the corps is £112,410. There is also a sum of £11,650 provided for the pay of nurses, extra duty of regimental orderlies and miscellaneous labour. For the pay of surgeons of the Militia, including allowance for medicine &c., £6000 are provided, and £500 for departmental pay, Militia Reserve Medical Staff Corps. Under the head of "Army Sanitary Committee" there is a charge of £1150, being an allowance of three guineas a day, when employed, to one civilian member, and contingent expenses of the committee.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5782 births and 3836 deaths were registered during the week ending March 12th. The annual death-rate in these towns, which had been equal to 21·3 per 1000 in each of the two preceding weeks, further rose last week to 21·6. During the first ten weeks of the current quarter the death-rate in these towns averaged 21·9 per 1000, and was 2·3 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 16·1 in Derby, 17·1 in Birkenhead, 17·2 in Leeds, and 18·1 in Wolverhampton. The rates in the other towns ranged upwards to 28·9 in Cardiff, 29·0 in Huddersfield, 30·3 in Oldham, and 33·7 in Manchester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had increased in the preceding four weeks from 340 to 385, further rose last week to 412; they included 195 from measles, 83 from whooping-cough, 44 from scarlet fever, 32 from diarrhœa, 31 from diphtheria, 27 from "fever" (principally enteric), and not one from small-pox. No death from any of these zymotic diseases was registered last week in Wolverhampton, Derby, or Birkenhead; they caused, however, the highest death-rates in Huddersfield, Sunderland, and Manchester. The greatest mortality from measles occurred in Salford, Leicester, Bristol, Huddersfield, Manchester, and Sunderland; whooping-cough in Norwich, Oldham, and Plymouth; scarlet fever in Huddersfield; and from "fever" in Portsmouth. The 31 deaths from diphtheria in the twenty-eight towns included 13 in London, 4 in Manchester, 3 in Oldham, and 2 in Cardiff. Small-pox caused only one death in Greater London, and not one in any of the twenty-seven large provincial towns. Only 4 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had been 466 and 459 in the preceding two weeks, further declined last week to 433, and were as many as 72 below the corrected average. The causes of 92, or 2·4 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bristol, Preston, and in four other smaller towns. The largest proportions of uncertified deaths were registered in Sheffield, Halifax, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 22·5 and 23·6 per 1000 in the preceding two weeks, further rose to 25·0 in the week ending March 12th; this rate exceeded by 3·4 the mean rate during the same period in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 14·7 and 18·9 in Leith and Edinburgh, to 28·2 in Paisley and 29·4 in Glasgow. The 625 deaths in the eight towns last week showed a further increase of 36 upon the number in the preceding two weeks, and included 43 which were referred to measles, 25 to whooping-cough, 14 to scarlet fever, 11 to diarrhœa, 7 to diphtheria, 1 to "fever," and not one to small-pox; in all, 101 deaths resulted from these principal zymotic diseases, against 99 and 98 in the previous two weeks. These 101 deaths were equal to an annual rate of 4·0 per 1000, which exceeded by 1·7 the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of measles, which had been 23, 30, and 27 in the preceding three weeks, further rose last week to 43, of which 16 occurred in Glasgow and 27 in Aberdeen. The 25 deaths from whooping-cough showed a decline of 7 from the number in the previous week, and included 13 in Glasgow, 3 in Dundee, and 3 in Aberdeen. The 14 fatal cases of scarlet fever also showed a decline from the numbers in recent weeks; 7 were returned in Edinburgh and 3 in Glasgow. The 11 deaths attributed to diarrhœa corresponded with the number in the previous week, and included 4 in Glasgow and 3 in Edinburgh. The 7 deaths from diphtheria, of which 4 occurred in Edinburgh and 3 in Glasgow, exceeded the numbers in recent weeks. The single death from "fever" was registered in Paisley. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 121 and 142 in the preceding two weeks, declined again last week to 135, which were 56 below the number returned in the corresponding week of last year. The causes of 72, or more than 11 per cent., of the deaths registered during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 35·3, 30·7, and 28·1 per 1000 in the preceding three weeks, rose again to 31·3 in the week ending March 12th. During the first ten weeks of the current quarter the death-rate in the city averaged 31·3, the mean rate during the same period being but 20·8 in London and 21·5 in Edinburgh. The 212 deaths in Dublin last week showed an increase of 22 upon the number in the previous week; they included 5 which were referred to "fever" (typhus, enteric, or simple), 1 to measles, 1 to scarlet fever, 3 to whooping-cough, and not one either to small-pox, diphtheria, or diarrhœa. Thus the deaths from these principal zymotic diseases, which had been 14 and 15 in the preceding two weeks, declined last week to 10; they were equal to an annual rate of 1·5 per 1000, the rates from the same diseases being 2·1 in London and 3·2 in Edinburgh. The deaths from "fever" corresponded with the number in the previous week, and those of whooping-cough showed an increase, while the mortality from scarlet fever was smaller than in any previous week of this year. The deaths of infants showed a decline of 2, while those of elderly persons showed a further increase upon the numbers returned in the preceding two weeks. Seven inquest cases and 6 deaths from violence were registered; and 59, or more than a quarter, of the deaths occurred in public institutions. The causes of 30, or more than 14 per cent., of the deaths registered during the week were not certified.

BRISTOL CHILDREN'S HOSPITAL.—At the annual meeting of the supporters of this hospital on the 5th inst., it was reported that 584 children and 29 women have been under treatment as in-patients during the past year—being 70 per cent. more than the average number of the last ten years in the old building. In the out-patient department 755 women and 2116 children attended respectively 8305 and 16,743 times. The income just met the expenditure, the former amounting to £2109, and the latter to £2091.

"Audi alteram partem."

THE JUBILEE AND THE HOSPITALS.

To the Editors of THE LANCET.

SIRS,—As the Queen's Jubilee requires commemoration in some manner worthy of her great reign, I beg to suggest that no better method could be found than to raise a fund for the permanent endowment of our great London hospitals. I think a fund such as you suggested last week, to free them from debt, would not be adequate to the occasion. The Imperial Institute and Church House will be supported by Loyalists and Churchmen all over the world, but unless some great scheme is started in London, to which all will feel bound to contribute, the money of the charitable will be frittered away in a thousand hobbies of doubtful utility. A sum of this magnitude would never be raised in the ordinary method of appeals to the benevolent few; but if the scheme were to receive the assent of the great body of the people, a voluntary assessment of a fiftieth part of the income of all those who now pay income-tax would receive a response sufficient for even so great a purpose.—I am, Sirs, your obedient servant,

Clifford-st., Bond-st., W., March 15th, 1887. G. SLIGHT, M.D.

*** We shall be only too happy if Dr. Slight's suggestion should find favour, and prove successful. Could not the heads of the medical colleges and the great hospitals organise a meeting to give form to the extensive wish to signalise the Jubilee by help to the hospitals?—ED. L.

PERFLATION IN EMPYEMA.

To the Editors of THE LANCET.

SIRS,—The method of perflation described by me in your issue of July 31st, 1886, was capable of improvement, and has been improved in two essential particulars. 1. The idea suggested by Dr. Sansom at the last meeting of the Royal Medical and Chirurgical Society (which the lateness of the hour prevented my acknowledging), as to the advantages of an antiseptic air-filter instead of a column of antiseptic fluid, occurred to me several months ago, and was put into practice. Instead of containing a short column of carbolic acid solution, the Woolff's bottle was filled with tow saturated with liquefied carbolic acid or with strong solution of thymol, with a view to securing the following advantages: (*a*) absence of any fluid which, through inadvertence, might be allowed to run into the chest; (*b*) considerable subdivision of the air during its passage through the tow, and thorough mechanical cleansing of the same; (*c*) increased facility for warming the air in the bottle when necessary. At an early date, however, I discarded the Woolff's bottle, preferring to use a broad tube (one inch and a half in diameter and about ten inches long) fitted at either end with an indiarubber plug and short glass tube, and packed with medicated tow. This apparatus can lie flat on the table or on the bed, and is simply a broader segment inserted in the length of the tubing. It can readily be warmed by placing it in an appropriate hot-water trough, or by keeping it surrounded with hot flannel. 2. For the other improvement I am indebted to a suggestion from Mr. Marten, house-physician to Addenbrooke's Hospital, Cambridge. Instead of Richardson's bellows, I now employ a Fletcher's foot-bellows. This apparatus enables the operator to use both hands, whilst his foot works the bellows and controls the delivery of air. It thus becomes possible (provided a steam spray-producer is available) to dress an empyema without a trained assistant. The pressure which can be obtained from Fletcher's bellows is in excess of surgical requirements. But it is easy to obviate this difficulty with the help of a screw-clamp placed on the tubing between the chest and the air-filter. By this means the diameter of the tube may be varied so as to regulate to any extent the quantity of air delivered into the chest. I may add that perflation can be applied whether two openings exist into the chest or only one. A free incision (if possible in the posterior or lateral aspect of the chest) will usually suffice. I believe, however, that an advantage is often gained by making in front a counter-opening, which need not be so large as the posterior wound.

I remain, Sirs, yours truly,

Curzon-street, Mayfair, March 11th, 1887. WM. EWART.

P.S.—I avail myself of this opportunity of setting at rest the doubts expressed by some Fellows of the Royal Medical and Chirurgical Society as to the nature of the specimen exhibited as gangrenous lung tissue on the 8th inst. Dr. Délepine's microscopical examination confirms the conclusion drawn from naked-eye appearances that this was a portion of the lung, and the surmise that embolism was the cause of the gangrene.

CANCER OF THE BODY OF THE UTERUS.

To the Editors of THE LANCET.

SIRS,—I shall be glad to be allowed to correct an error in my letter on the above subject which appeared on March 5th. In referring to Case 22, described in Dr. John Williams's Harveian lectures, I stated that, according to my recollection, the disease had commenced in one of the fibroids, and had spread thence to the uterine wall. I have since had an opportunity of making a more complete examination of the specimen, and from the appearances presented by deeper sections, it is clear that the uterine wall, and probably the mucous membrane, was the site of the primary disease.

With regard to the question on which our opinions differed—viz., the frequency with which cancer affects the body of the uterus,—I find that at the Middlesex Hospital we have had only two such cases in the post-mortem room during the last eleven years. This may possibly be due, as Dr. Williams suggests to me, partly to the fact that such, not being recognised outside as cases of malignant disease, are not sent into our cancer wards, and that, when diagnosed, they are considered too "good" to be given up to a hospital. On the other hand, Dr. Williams's experience of such cases may be exceptionally large, as they would certainly present difficulties, and on that account would be likely to be submitted for the opinion of a consultant.

I am, Sirs, yours truly,

J. KINGSTON FOWLER, M.D.

Clarges-street, W., March 15th, 1887.

IODOFORM AS AN ANTISEPTIC.

To the Editors of THE LANCET.

SIRS,—The doubts cast upon the antiseptic power of iodoform are surprising, and must surely be contradicted by the experience of every practical surgeon. It really seems absurd to quote instances to prove the superiority of iodoform (through the penetrating character of its volatile particles) to other antiseptics, it is a matter of such daily experience. I will just mention one case, however, if you will permit me. When surgeon on board the Orient steamship *Lusitania* (temporarily an armed cruiser), I had an invalided engineer from the Nile boat corps handed over to my charge at Alexandria, with the worst "poisoned hand" I ever saw. It was riddled with abscesses back and front; it had been deeply incised in several places, the pus burrowing up the tendon sheaths above the wrist; and it was horridly offensive. It had been treated with carbolic baths continuously. I kept it four hours in a carbolic bath, and then syringed it well and dressed it with carbolic solution (1 in 40). At night it was as offensive as ever. I then wrapped the fingers and hand with strips of lint on which was spread a weak iodoform ointment (twenty grains to an ounce of zinc ointment). The hand in the morning was *perfectly sweet*. The dressing was simply renewed, first twice a day, then daily. The healing process commenced immediately, discharge rapidly diminished, and there was never the slightest odour from the hand after the first dressing. The man's temperature became normal (it had been 101°), appetite good, and he went ashore with his hand healed. I would only say, in conclusion, that, as my supply of this invaluable drug was very small, I learned how exceedingly small an amount was necessary, and that the waste to which I had been accustomed in London hospitals was simply sinful. To powder a wound over or stuff a sinus with pure iodoform is utterly unnecessary. I am convinced that drachms are used when grains would suffice, especially in hospital practice.—I am, Sirs, yours obediently,

March, 1887. J. P. GLOVER, M.D. Lond.

INEQUALITY OF THE PUPILS IN TUBERCULAR MENINGITIS.

To the Editors of THE LANCET.

SIRS,—In your issue of the 12th ult. I notice a letter from my friend Dr. Alderson. The subject—"The Inequality of the Pupils in Tubercular Meningitis"—is one that occupied my attention considerably some time ago, when I had the opportunity of examining the eyes of several children suffering from this disease. Granting that inequality of pupils is liable to exist in these cases, I own that I am somewhat surprised that Dr. Alderson—whom I know to be a very careful observer—should attach such enormous weight to this single symptom. Tubercular meningitis is simply acute tuberculosis affecting (principally) the pia mater at the base of the brain, with serous exudation into the lateral ventricles; and it seems to me that it is a mere accident whether pressure is greater on one side than on the other, or whether it is equal on both sides. To reject the diagnosis of tubercular meningitis because pressure is symmetrical would therefore appear to be going rather too far. I can give Dr. Alderson details of an undoubted case of tubercular meningitis which terminated fatally, in which there was wide dilatation of *both* pupils, with immobility under the strongest light, and also double optic neuritis. Personally, I should attach greater importance to the fact of dilatation being present (whether equal or unequal), and especially to the insensibility (partial or complete) of the iris under the stimulus of light. Dr. Alderson does not tell us whether he examined the fundi of any of his cases, and whether he found any change therein indicating a descending perineuritis. It would be interesting to hear the opinions of others on these diagnostic points, which is my apology for sending this letter to you instead of direct to my friend.—I am, Sirs, your obedient servant,

A. ST. CLAIR BUXTON, F.R.C.S.,
Assistant-Surgeon to the Western Ophthalmic
Orchard-street, W., March, 1887. Hospital.

ANATOMY AND PHYSIOLOGY IN CHARACTER.

To the Editors of THE LANCET.

SIRS,—Accept my thanks for your careful analysis of my recent work. One point your reviewer has misapprehended. I expressly state that the rule for shrewish men and women to have clear, pink skins has many exceptions. My book is so compressed that misapprehensions are perhaps not unnatural. The *Saturday Review*, for instance, declares that many non-shrewish persons have round backs. I myself said this as clearly as I knew how. I am sure you will permit me to advert to a matter of fact. In matters of opinion I am well aware that I run counter to so much popular belief and feeling that the wide and generous reception already given to my book excites my genuine surprise. I am, Sirs, yours obediently,

Birmingham, March 14th, 1886. FURNEAUX JORDAN.

VEXATIOUS ACTIONS AGAINST MEDICAL MEN.

To the Editors of THE LANCET.

SIRS,—The following short statement of facts may perhaps serve as a warning to some of my fellow-practitioners, if there are still any who need it, and will in any case, I trust, help to strengthen the hands of those who are striving for the reform of a most unjust law.

One fine day in August, when most of my professional neighbours were enjoying their holidays, I was served with a magistrate's order, directing me to visit and report upon the state of mind of a supposed lunatic. I did as I was ordered, found that the individual was undoubtedly insane, and certified to that effect. Next day she was brought before the magistrate, who satisfied himself by personal examination of the correctness of my opinion, and signed an order for her removal to a public asylum, where she was detained for two months. Some months afterwards I was served with notice of an action, then with a long list of "interrogations"; then one of the plaintiff's witnesses was examined by commission; and at last, after various other distractions and annoyances, was put to the inconvenience of a trial extending over four days, at the conclusion of which the jury without hesitation gave a verdict in my favour, the judge awarded me "costs," and I was overwhelmed with friendly congratulations. Again an interval of a few months, and I receive a bill for £240 8*s.* 1*d.* The plaintiff professes herself a pauper. I am told that it is open to me to institute proceedings in bankruptcy against her; but I have had enough of law for the present, and even the lawyers do not hold out much prospect of a successful result. There is nothing to be done but to pay the demand as best I can out of hardly-earned savings, and with the hope that the time is not far distant when such flagrant injustice will be a thing of the past.

I am, Sirs, yours truly,

March, 1887. A VICTIM OF THE LAW.

THE ACCOMMODATION FOR PRISONERS AWAITING TRIAL.

To the Editors of THE LANCET.

SIRS,—I am directed by the Mayor of Marlborough to write to you on the subject of your remarks on the Report of the Committee of Inquiry into the Accommodation for Prisoners awaiting Trial, in your issue of the 12th inst. So far as Marlborough is concerned, there seems to be no doubt that the Committee's Report is founded upon information furnished by the Governor of Devizes Prison of the state of things antecedent to 1885, and does not take cognisance of alterations and improvements effected by the Town Council since that date. As regards the sanitary arrangements, there has been a complete change, a proper watercloset being now provided in a separate room, and the repulsive practice as quoted by you from the report done away with. The prisoners' room has also been enlarged, and improvements effected in the lighting and warming of it. I may add that the accommodation now provided has been favourably reported on by one of Her Majesty's inspectors, and can compare favourably with that of any other town in the county of Wilts. I trust that, for the credit's sake of our town, you will give prominence to this letter.

I am, Sirs, your obedient servant,

E. LLEWELLYN GWILLIM,
Marlborough, Wilts, March 16th, 1887. Town Clerk.

"PARTIAL ENTEROCELE (IRREDUCIBLE) ASSOCIATED WITH HYDROCELE OF THE HERNIAL SAC."

To the Editors of THE LANCET.

SIRS,—Since the publication of my case of partial enterocele, Mr. Day, jun., of Harlow, who was present at the operation, has sent me a few facts of importance which add to its interest: "She had not been wearing a truss previously to the operation, and her local inflammatory symptoms before she was sent up to town had been *nil*. Since the operation her condition has been excellent, and she has had no further trouble with regard to the rupture."

I am, Sirs, yours sincerely,

March, 1887. WILLIAM HY. BATTLE.

LIVERPOOL.

(*From our own Correspondent.*)

OUR LOCAL ASSIZE COURTS AND THE ACCOMMODATION FOR PRISONERS.

THE committee appointed by the Government to inquire into the accommodation for prisoners awaiting trial were satisfied with the arrangements made in our Assize Court. The steps from the prisoner's dock lead to a large waiting-room, closely adjoining which are a sufficient number of separate cells, both for male and female prisoners, with every proper sanitary arrangement. These courts were erected in 1854, and it would appear that so far as the prisoners are concerned nothing is required. But, as remarked in previous letters, the accommodation for witnesses is most inadequate, and, as Liverpool is probably not singular in this respect, it is to be hoped that the Government may, now that the prisoners have been considered, inquire into the arrangements made for other persons concerned—the witnesses, the jurors, and all whom justice requires to be present.

DEATH OF DR. MATTHEW HILL OF BOOTLE.

Dr. Matthew Hill of Bootle died last week. The deceased, who had practised in Bootle for many years past, was well known, not only in his professional capacity, but also as having taken an active part in municipal affairs, and recently filled the office of Mayor of Bootle. His funeral, which took place at Anfield Cemetery on the 12th inst., was a military one, the deceased having been surgeon-major to the 1st Liverpool Rifle Volunteers, and it was attended by a very large number of medical and lay friends.

THE OLDHAM POISONING CASE.

The last penalty of the law was inflicted upon Elizabeth Berry, on the 14th inst., within the walls of Her Majesty's prison, Walton-on-the-hill, which is virtually the borough gaol. Formerly all prisoners sentenced to death at the Liverpool assizes were hanged within the county gaol at Kirkdale, but recent changes have made it necessary to alter this arrangement, and in future male prisoners will be executed at Kirkdale, females at Walton. This makes the fourth female executed in this county for murder by poisoning within the last three years. It being the first execution at this gaol, great care was taken to ensure the prompt and humane carrying out of the sentence. The wretched woman was spared the task of ascending steps to the scaffold, it being on a level with the prison yard, and death was almost instantaneous.

THE HOSPITAL FOR WOMEN.

A special general meeting of the governors of this hospital was held on the 11th inst., when the amended laws were submitted for approval. Among them one of the most important was that the election of medical officers shall in future be by the committee, instead of by the governors. Another was as follows: "No operation of dangerous character or which involves abdominal section shall be performed, except in cases of extreme emergency, without previously summoning a consultation of consulting and acting surgeons for in-patients, and no such operation except as aforesaid shall be performed in the hospital without a consultation between the operator and one of the before-mentioned officers. No person who is not officially connected with the hospital shall be called in consultation without the acquiescence of the medical staff. No medical gentleman unconnected with the hospital staff shall be permitted to assist at any operation without the acquiescence of the medical staff, unless in cases of emergency; and such cases shall be reported to the committee, with the names of the gentlemen assisting thereat." The committee have thus acted upon the recommendation of the Liverpool Medical Institution Committee, appointed as a committee of inquiry into the 1885 cases of abdominal section. The proposed amendments were unanimously adopted.

THE PIANO-ORGAN NUISANCE.

An Italian organ-grinder was recently summoned before the county magistrates for persisting in playing a piano-organ after being requested to go. The offence was committed close to the residence of an invalid lady, who had suffered severely in consequence; and her son was compelled to prosecute, not to punish so much as to prevent the nuisance from being repeated. By recent local Acts, any residents in the borough and suburbs may request musicians and singers to remove "out of hearing," and any refusing to do so are liable to be fined to the extent of forty shillings. The wisdom of this wholesome regulation will be appreciated by medical men, who know well what suffering is inflicted upon themselves and others by this intolerable nuisance. In this case the defendant was made to pay the costs, and warned not to repeat the offence.

THE NETHERFIELD ROAD HOSPITAL.

At the last meeting of the City Council the appointment of Dr. Robert Robertson as visiting physician to the City Hospital, Netherfield-road, was confirmed.

Liverpool, March 15.

PRISON SURGEONCIES IN SPAIN.—The profession is so overcrowded and the desire to obtain some public appointment so universal in Spain, that a few vacancies in the medical officerships of the penal establishments having recently been notified, the applications for the appointments poured in on the astonished officials to the number of 3200!

EDINBURGH.

(From our own Correspondent.)

UNIVERSITY OF EDINBURGH.

A NUMBER of honorary degrees about to be conferred by the University at the annual graduation ceremonial in April have been announced. Amongst those upon whom the honorary degree of D.D. is to be conferred are Professor Duff, of the United Presbyterian College, and the Rev. Thomas C. Edwards, M.A., Principal of the University of Wales. The degree of LL.D. is to be conferred, amongst many others, upon Professor Dittmar, of Anderson's College, Glasgow; Professor Edward Dowden, of Trinity College, Dublin; Professor Momerie, of King's College, London; and Sir Bhagvat Sinh, Thakoor of Gondal, an Indian prince, who has attended lectures in the Faculty of Medicine during the last two years. The same degree has been offered to Dr. Gunning, late of Rio Janiero, Mons. F. Xavier Michel, and Mr. C. J. Lyall.

A YEAR'S DISPENSARY WORK.

The annual report of the New Town Dispensary, an historical medical institution in Edinburgh, and a very popular charitable agency for the relief of the sick poor, shows that upwards of 9500 patients have been treated under the auspices of the dispensary in the last twelve months. Over 1000 vaccinations have been successfully performed during the same period, and 2300 patients visited in their own homes by the medical staff. The balance-sheet shows a similarly satisfactory condition in other respects.

Edinburgh, March 16th.

ABERDEEN.

(From our own Correspondent.)

ABERDEEN GENERAL DISPENSARY.

THE annual meeting of the managers of the Aberdeen General Dispensary was held on Friday, the 4th inst., when the annual report was read and approved. It showed that relief had been afforded to 8290 cases during the past year, and that 6372 visits had been paid to 2549 patients at their homes; there were 220 obstetric cases, 697 children were vaccinated, and 770 dental operations had been performed. There were also 219 cases in the ear and throat department, which is under the charge of Dr. McKenzie Booth and Dr. Edmond. Another member of the staff has arranged to attend twice a week for the treatment of diseases of women. The finances of the dispensary show a pleasing exception to those of our other charitable institutions; the income exceeds the expenditure by £378 19*s*. The members of the staff and other officials were re-elected. The Committee of Management, at the request of the Medical Faculty of the University, had under consideration the appointment of a public vaccinator in connexion with the dispensary, whose position and qualifications to grant certificates to the students would be recognised by the Local Government Board. The committee approved of such an appointment if the necessary funds could be provided without entrenching on those of the institution. At present the members of the staff do the work in rotation, each one attending once a week for two months; but they are not qualified to grant certificates to students.

THE ROYAL INFIRMARY.

A quarterly court of the managers of the Royal Infirmary was held yesterday. Dr. Angus Fraser was promoted to the position of second physician, rendered vacant by the death of Dr. Beveridge, and Dr. Blaikie Smith, assistant-physician, was appointed third physician. For the office of assistant physician Dr. Rodger was the only candidate, and he was elected unanimously. By this appointment the office of pathologist to the infirmary, which Dr. Rodger held for seventeen years, becomes vacant, and it is generally expected that Professor Hamilton will be elected to fill it. The annual financial account, as presented to the meeting, discloses anything but a satisfactory state of affairs. The expenditure still largely exceeds the income, and the same has to be said of the convalescent hospital. The "Jubilee Fund" for the extension of the infirmary now amounts to

Digitized by Google

£11,531 14s., and the committee in charge of it are hopeful that the necessary sum, £30,000, will be subscribed before the required time. They are about to make a personal appeal to every elector in the city and county of Aberdeen, and in the county of Kincardine.

ABERDEEN UNIVERSITY.

The winter session closes on the 25th of this month and the professional examinations begin on the Monday following. Professor Cash has appointed Dr. John Gordon to be assistant in materia medica.

THE CITY HOSPITAL.

The Epidemic, or City Hospital, as it is now called, is in disgrace. Some time ago grave charges were made by the Trades Council of the city as to the character of the nurses, the want of cleanliness in the beds and persons of the patients, and the want of proper discipline in the hospital generally. These charges were practically admitted by the Public Health Committee, and were the means of bringing about a marked improvement in the general management of the hospital: the wards were made more comfortable, and it was said a staff of well-trained nurses had been engaged. But a sad accident, which took place lately, shows that things are far from what they should be. Of the few cases of typhus fever, three were sent to the Children's Hospital as cases of typhoid fever, and were admitted as such, and unfortunately before the true nature of the fever was detected a probationer nurse caught the infection. She was removed to the City Hospital, and there, it is said, she was attended by a nurse who also had to attend to some case of measles in an adjoining but entirely separate ward. On one occasion, while the nurse was absent, her typhus fever patient got out of bed in a state of delirium, and in her wandering through the ward set fire to the bedclothes which she had wrapped round her. She was found lying on the floor terribly burnt, and in a few days she succumbed to the combined effects of the fever and burning.

HEALTH OF THE CITY.

The death-rate for some time has been unusually high. Scarlet fever, measles, and whooping-cough are all epidemic; there have also been a great many cases of typhoid fever and a few of typhus. The cases of typhus were on the whole mild, and it is satisfactory to find that this disease is not likely to become epidemic.

March 15th.

DUBLIN.

(From our own Correspondent.)

ROYAL COLLEGE OF SURGEONS IN IRELAND.

MEETINGS have been held between delegates from the College of Physicians and the Royal College of Surgeons in Ireland in reference to the proposal to empower the London Colleges to confer the M.D. degree. They have recommended the Dublin Colleges to lodge a *caveat* against the proposal unless similar privileges be granted to them. From a correspondence with the Edinburgh and Glasgow medical and surgical corporations, it appears that in Scotland there is an actual desire to get powers similar to those asked for by the London corporations. In Dublin, however, there is no desire to obtain such a privilege unless it be given to the London bodies. A meeting of the Council of the College of Surgeons will be held on Thursday, the 17th inst., when a motion by Sir Charles Cameron will be under consideration. The motion is to the effect that, should counsel's opinion be favourable as to the legality of the College combining with the Apothecaries' Hall, a conference with that body be invited with the object of preparing a scheme of examination to be held by that corporation and the College of Surgeons conjointly. — A petition in reference to the grievances under which army medical officers at present labour has been sent to the House of Commons by the Council of the College.

CITY OF DUBLIN HOSPITAL.

Mr. H. Gray Croly, senior surgeon to this institution, some time since suggested that "observation wards" would be found convenient and useful, and the recommendation has now been carried into effect. This desirable result is due to Mr. Marcus Tertius Moses, one of the governors, who has built at his own expense substantial male and female observation wards at the rear of the hospital. At a meeting of the Board of Governors last week a vote of thanks was accorded to Mr. Moses for his liberality.

DEATH OF DR. WILLIAM BEAMISH.

This gentleman, who died at his residence, near Dublin, on the 7th inst., practised for many years in Cork, where he was well known and justly esteemed for many sterling qualities. He held the post of senior physician to the Cork Fever Hospital for many years, and also was surgeon to the Cork Male and Female Prisons. About four years since he retired from practice and removed to Dublin. The deceased was the author of a paper on Fever, and a communication "On the Pathology, Prevention, and Treatment of Asiatic Cholera, with cases in the Epidemics of 1849, 1853, and 1866."

ZYMOTIC DISEASES IN DUBLIN DURING FEBRUARY.

As compared with the previous month there was a large decrease in the deaths from scarlatina. Eight deaths were recorded from enteric fever, as compared with four the month preceding. On the whole there was a slight decline in the zymotic death-rate as contrasted with January, and the rate was much below the average of the month for the previous ten years.

MONKSTOWN HOSPITAL.

The report for the past year is a satisfactory one, the cases treated being in excess of that of 1886, and the cost of management somewhat less. On one item, that of pay patients, there has been a considerable increase. This arises from the payments made by the Admiralty, the hospital being the naval sick quarters for Her Majesty's ships on the Kingstown station.

ADELAIDE HOSPITAL.

The annual meeting of the friends of this institution was held on Tuesday, the 15th inst., and the report shows the hospital to be in a very flourishing condition, and to be accomplishing a good work in Dublin. There were 482 cases in the surgical wards during the year, necessitating 213 operations, the deaths among these cases amounting only to a little over 2 per cent. The committee refer to the great prevalence of phthisis among the poorer classes in Dublin, and state that year by year the need of a special institution for cases of this disease becomes more urgent.

Dublin, March 15th.

BELFAST.

(From our own Correspondent.)

THE MEDICAL STUDENTS' CONVERSAZIONE.

THE first conversazione in connexion with the Medical Students' Association was held in Queen's College, on March 10th. This society was established for social intercourse, the discussion of subjects peculiar to the medical profession, and for bringing before the students matters affecting their position, so as to give united expression of opinion. All the rooms of the College were available for the evening, the entrance and examination halls being very profusely decorated. There was a very large assemblage of students and their lady and gentlemen friends; and as the professors and graduates appeared in their academic costume the scene was very picturesque. Among those present were the Mayor of Belfast, the General in command of the district, and the President of Queen's College. The tea-tables were arranged round the examination hall, and were presided at by the wives or lady friends of the professors and members of the hospital staffs at which the students attend. This hall was decorated and illuminated by the electric light. The band of the Queen's Royal West Surrey Regiment was stationed in the hall, where they performed during the evening. In the chemistry lecture-room Professor Letts was very successful in a series of popular chemical experiments, and in the physics lecture-room Dr. Everett gave a number of experiments on vibration. Professor Fitzgerald showed several electrical experiments, and a number of microscopes were exhibited in the council chamber. A number of amateurs executed admirably a variety of musical items, while a very successful series of *tableaux vivants* were given by the students in the en-

Digitized by Google

trance hall. A committee of the students (of which Mr. Weatherup, B.A., and Mr. Haslett were secretaries) had charge of the arrangements, and to them the great success of the entertainment is due. It is hoped the conversazione will become an annual one.

ULSTER MEDICAL SOCIETY.

At a meeting of this Society held on March 9th, Dr. Esler showed an ovarian cyst which he had successfully removed, and Dr. Byers introduced a discussion on the treatment of abortion. Dr. Dempsey read a paper on the same subject, and Professor Dill took part in the subsequent discussion.

Belfast, March 16th.

PARIS.

(From our own Correspondent.)

TYPHOID FEVER.

THE frequency of typhoid has been steadily on the increase for the last six weeks, and at the present time there is an unusually high mortality. In my letter of Feb. 5th I had anticipated this possibility, but, strangely enough, the number of deaths registered during the following week was exceptionally small, and it was thought by many that the danger had been over-estimated. Since then, however, the death-rate has increased week by week, and the last two returns have been forty-one and forty respectively. Comparing these numbers with the statistics for last year, which gave 1009 fatal cases for the twelve months, it will be seen that the mortality during the past fortnight has been more than twice the average. The water-supply is now said to be derived from pure sources, but if this is true the temporary sojourn of the Seine water in the mains has produced a contamination of the water-pipes that has not yet disappeared. I have not seen a glass of water in Paris for the last two months that has not been visibly full of organic impurities and unpleasantly suggestive of the infinitesimally small.

PASTEURIANA.

It has been tacitly agreed at the Academy of Medicine that the discussion upon rabies be suspended until M. Pasteur's return, but in the meanwhile advocates and opponents of the method remain as uncompromisingly hostile as ever. Whilst the *Annales de l'Institut Pasteur* continues to herald the enthusiasm of its directors, its adversaries of the medical and political press throw in a discordant note from time to time under a new stereotyped heading, which recurs with lugubrious monotony—the "Nécrologie Pasteur." The *Journal de Médecine de Paris* has discovered two new cases in Russia. The first of these is quoted from the Warsaw newspapers, and relates to the wife of a farmer named Ozimaki, who was bitten nine months previously, and underwent the treatment by the first method in Paris. The second was a peasant named Wassilieff, inoculated on the third day after the bite at St. Petersburg, who died within a few days of the completion of the treatment. It has also been shown by the inoculation test that the death of Bergé, at Bordeaux, was due to rabies, and the fact is not contested. To these the *Journal de Médecine* adds three new victims for France—the child Santés of Algiers; an Italian, Rovati of Modena; and a man called Alphand, said to have died of the paralytic form of the disease. In the *Annales* it is stated that there is no evidence of rabies in this last instance, and the death is attributed to another cause. *A propos* of rabies, it is somewhat surprising that those learned in "suggestion" should have hitherto neglected so promising a field for hypothesis and experiment. If, as the Paris Biological Society allows, the gonococcus can be annihilated with the greatest ease by neurypnologic command, why not also the virus of rabies? Does not M. Pasteur cure his patients by a kind of indirect auto-suggestion, or, to use the expression of forty years ago, by "credencive induction"? And, on the other hand, is not M. Peter morally responsible for the fatal results by a similar but baneful *action à distance!* Grave and important questions for students in hypnotism, and which will be none the less novel to them, if not exactly new.

NARCEINE.

M. Laborde has been studying for the last few months the action of a new narceine. The preparation of this substance is extremely difficult, and that found in the trade contains a large proportion of other alkaloids of opium. M. Duquesnel has succeeded in obtaining narceine containing only a small quantity of laudanine and codeine, and from numerous trials upon animals and upon man, M. Laborde states that this product has a happy sedative effect upon the nervous centres, and is an admirable medicine for whooping-cough and bronchitis, an opinion which is shared by M. Brown-Séquard.

A "SPECIFIC" FOR DIABETES.

At a recent meeting of the Société de Thérapeutique, M. Martineau stated that he had been treating diabetes for the last ten years, with almost invariable success, by a method which he had borrowed from a practitioner now dead. He had hitherto made no communication upon the subject, because he had wished to be perfectly certain that his conclusions were not premature. The treatment consists in the administration of a solution of carbonate of lithia and arseniate of soda in aerated water, to the exclusion of all other drinks. Besides taking this with his meals, the patient uses the same as a beverage when thirsty at other times. M. Martineau affirms that this regimen has cured sixty-seven of seventy diabetic patients he has had occasion to treat.

MEMORIAL TO THE FRENCH ARMY MEDICAL STAFF.

A monument has been erected in the Salle d'Honneur of the Val-de-Grâce, the military hospital and school of medicine, to the memory of those members of the medical staff of the French army who lost their lives in the performance of their duty during recent campaigns. They number one hundred and twenty-three, and of these eleven were killed in action by the enemy's fire. The others fell victims to malaria, typhoid, cholera, and other diseases, and although, from a military point of view, their death was a less glorious one, still their devotion to the public service is honourably recognised.

THE FACULTY OF MEDICINE.

M. Brouardel has been appointed Dean of the Faculty for a period of three years. For the post of perpetual secretary of the Academy of Medicine the candidates are M. Jules Bergeron and Professor Jaccoud.

Paris, March 16th.

THE SERVICES.

Deputy Surgeon-General Sir J. Hanbury, K.C.B., Principal Medical Officer of the Home Military District, has been ordered on foreign service, and will embark at once for the Mediterranean.

Deputy Surgeon-General A. F. Bradshaw has been appointed Principal Medical Officer on the Staff of the Northern District at York; Surgeons J. G. Black, M.D., J. Kearney, M.D., C. A. Renny, M.B., and E. C. G. Dell have arrived in India for duty in the Bengal Presidency; Surgeon B. O. W. Norfor, M.B., has joined at Canterbury for duty on his return from Egypt.

WAR OFFICE.—Royal Malta Fencible Artillery: Surgeon Lorenzo Manché, M.D., to be Surgeon-Major.

ADMIRALTY.—Staff Surgeon Thomas Bolster has been promoted to the rank of Fleet Surgeon in Her Majesty's Fleet.

The following appointments have been made:—Staff Surgeons E. R. H. Pollard and Robert W. Williams, to the *President*, additional; Surgeon Edward G. Swan, to the *Imogene;* Surgeon George A. Draper, to the *Duncan:* Surgeon Alexander L. Christie, to the *Devastation;* and Mr. John Elliott to be Surgeon and Agent at Bantham.

ARTILLERY VOLUNTEERS.—1st Aberdeenshire: James Aymer, M.B., to be Acting Surgeon.

RIFLE VOLUNTEERS.—2nd Cambridgeshire (Cambridgeshire University): Surgeon Bushell Anningson is granted the honorary rank of Surgeon-Major.—1st Elgin: George Leslie Hodgson Milne, M.B., to be Acting Surgeon.—1st Volunteer Battalion, the Buffs (East Kent Regiment): Honorary Assistant-Surgeon W. Beet, M.D., resigns his commission.—2nd Volunteer Battalion, the Loyal North Lancashire Regiment: John Edwin Scowcroft, M.D., to be Acting Surgeon.—West Suffolk: Acting Surgeon H. C. C. Shaw resigns his appointment.

MEDICAL NOTES IN PARLIAMENT.

The Lunacy Acts Amendment Bill.

IN the House of Lords, on the 10th inst., the Lord Chancellor, in moving that the report of the amendments to this Bill made in committee be agreed to, said that he proposed to amend Subsection 11 by inserting a provision into it to the effect that where a person has been sent to an asylum or a private house, and has not been visited by a County Court judge or a magistrate having jurisdiction at the place where he is confined within seven days after the commencement of such confinement, the person confined shall have a right to be seen by any county court judge or any magistrate having any jurisdiction whom he shall designate.—The Earl of Selborne objected to the proposed alteration on the ground that it did not carry his view into effect.—Lord Herschell also objected to the amendment on a similar ground.—After some conversation, Subsection 11 was struck out, and the further consideration of the proposed amendment was postponed to the next stage of the Bill.—The Earl of Selborne said that on the third reading he would move as an amendment that the magistrate who made the order should be the person who visited the lunatic.—Several other amendments proposed by the Lord Chancellor were agreed to.

Accommodation for Prisoners awaiting Trial.

On the 15th inst., the Marquis of Ripon asked whether Her Majesty's Government intended to lay before Parliament the report of the Committee appointed by the Home Department to inquire into the state of the lock-ups and other places in which prisoners awaited trial in various parts of the country.—Earl Beauchamp stated that the paper referred to had been presented to Parliament, and was circulated on the 11th inst. The question was a grave one, and as soon as the report reached the Home Secretary he took it into his consideration, and addressed a circular to the county and borough authorities. But those matters did not rest entirely with those authorities, as the sanction of the Treasury might be necessary before any expenditure was incurred.

In the House of Commons on the same day, in reply to Lord Elcho, who asked the Secretary of State for the Home Department whether, in all cases when in consequence of the report of the committee on the accommodation of untried prisoners it was proposed to rebuild, extend, or otherwise alter the proposed accommodation, Her Majesty's Government would be prepared to examine the plans before the proposed works were carried out, in order to see that the intended alterations complied with the recommendation of the committee, and were in every respect suited to the requirements of the case.—Mr. Matthews stated that in the circular which he had lately issued he had invited the local authorities to communicate with him what works they propose to undertake. Such communications he should refer to the Surveyor-General of Prisons, and, acting on his advice, inform the local authorities of his own opinion on their proposals.

Smoke Abatement Bill.

On the 14th inst., Lord Stratheden and Campbell presented a Bill dealing with the abatement of smoke in the metropolis. The Bill was read a first time.

The Pharmacy Act Amendment Bill.

On Thursday night, the 17th inst., the Earl of Milltown moved the second reading of a Bill to amend "The Pharmacy Act, 1852," and "The Pharmacy Act, 1868." He said: The Bill is framed with the view of enabling the Pharmaceutical Society of Great Britain to make adequate regulations for the education and curriculum of those persons included amongst its members. The Bill is a short one, but the matter is important when it is considered that these persons alone have the power to dispense medicines and to sell poisons. The Pharmaceutical Society was founded in 1841, and received its charter in 1843. The Pharmacy Act, 1852, confirmed that charter, and made it for the first time penal for any unauthorised person to assume the title of pharmaceutical chemist. The Act of 1868 went a little further, and made it unlawful for anyone not duly qualified to sell or dispense poisons, or to assume the title of chemist and druggist. That Bill for the first time introduced the name druggist into an Act, and made it illegal for any person not duly qualified to sell poisons. The Society consists of members, associates, and registered apprentices, each having a separate qualification and having to undergo a separate education. Clause 6 of the Act 1868 apparently makes it imperative on the examiners to pass any person who presents himself for examination; and that being so, the Council of the Pharmaceutical Society have found themselves almost powerless in requiring such qualification in those who pass the qualifying examination as they deem absolutely essential for the safety of the public; and, in point of fact, persons who answer the questions may become qualified, although they have undergone no technical training at all. The Society has framed bye-laws for remedying this defect, and establishing what they consider a sufficient curriculum of study; but the Privy Council, to whom all bye-laws have to be submitted, found themselves unable to confirm them, as they were of opinion that the statutes of the Society did not empower them to frame any such bye-laws. This Bill has been introduced to remedy that defect. This Bill has the unanimous consent of the Pharmaceutical Society, and I believe, subject to a verbal amendment which I shall hereafter make, that it has the approval of the Lord Privy Seal. The second clause of the Bill gives power to the Council of the Pharmaceutical Society, in cases where persons have acquired in their judgment sufficient technical knowledge in England, in any other part of the United Kingdom, and in the colonies, to dispense with the three years' curriculum, but not with the qualifying examination. The Act is not to apply to Ireland. The Bill was then read a second time.

Lunacy.

The Lord Chancellor moved the third reading of the Lunacy Act Amendment Bill, and this having been agreed to, the Earl of Selborne, on the motion "That the Bill do now pass," moved an amendment providing that where a person was under care by order of a magistrate who had not thought it necessary to see the alleged lunatic, if subsequent examination became necessary, such magistrate should not be debarred from making that examination on the ground that he had signed the committal order.—The Lord Chancellor said if the amendment was inserted it must be on the authority of their Lordships' House, as he could not accept the responsibility of adopting a proposal which would practically allow a magistrate to sit in judgment on his own Act.

The House divided, when there were—for the amendment, 22; against, 46; majority against, 18. The Bill was then passed.

Brigade Surgeons in India.

In the House of Commons on the 11th inst., Colonel Hughes-Hallett asked the Under-Secretary of State for India whether he would take into consideration the case of brigade surgeons on the medical staff in India, having regard to the severe examinations they have to pass for their promotion, with a view to placing them, as was contemplated by the Royal Warrant of December 2nd, 1879, on the same footing as brigade surgeons in all other parts of Her Majesty's dominions as regards pay, position, and pension, instead of allowing them to remain as at present in India on the same pay after twenty-five and thirty years' service as surgeons-major, and subject at times to routine duties under medical officers of the latter rank who may be their juniors.—Sir J. Gorst replied that when the Royal Warrant created the rank of brigade surgeon in 1879 the Secretary of State for India declined to allow any increased expenditure to be cast on the revenues of India by reason of that warrant, and that the present Secretary of State adheres to that determination.

The Sewage Works at Barking.

In answer to Mr. Salt, Sir J. M'Garel Hogg stated that a tender amounting to £406,000 for the sewage works about to be executed at Barking was accepted by the Board in pursuance of the powers of the 135th section of the Metropolis Management Act, 1875, and of other provisions conferring jurisdiction upon the Board with reference to the disposal of sewage and refuse from the sewers of the metropolis and for the purpose of preventing the discharge of sewage sludge into the Thames. The £406,000 applies to the works at Barking only and is not final. A further sum will probably have to be expended in the completion of the works at both outfalls and the purchase of sludge ships.

The Relative Rank of Army Medical Officers.

On the 14th inst., on the motion to go into Committee of Supply on the Army Estimates, Dr. Clark desired to know

Digitized by Google

from the Government why a change of a prejudical character had been made in the relative rank of the medical officers in the service.—Dr. Tanner also pressed upon the attention of the Government the necessity of a reform in the Army Medical Department.

Staines Sewage.

On the 15th inst., in reply to Mr. Dixon-Hartland, Mr. Ritchie stated that the sums to be paid to the Thames Conservators by the metropolitan water companies were fixed by statute, and it was impossible for the Local Government Board to oblige the companies to devote some part of their profits to help to defray the cost of diverting the sewage from the river. The Staines Local Board had long evaded their statutory duties, with the result that the River Thames had been polluted with the sewage of the district. It devolved upon the Staines Local Board, as upon every other sanitary authority, to defray the cost of any sewage works required.

Vaccination in India.

In reply to Mr. Hunter, Sir J. Gorst stated that in British India vaccination is compulsory in certain selected areas only. No penalty is imposed for simple refusal or neglect to vaccinate a child. For mere disobedience to a magistrate's order to vaccinate the maximum penalty is 50 rupees. Contumacious and persistent disobedience may in certain cases entail a fine of 1000 rupees and six months' imprisonment.

Local Government Board Loans.

In reply to Mr. Leighton, Mr. Ritchie stated that the total amount of the loans sanctioned by the Local Government Board to be raised by local authorities during the year ended December 31st, 1886, was £2,827,867, being a decrease of £459,054 as compared with the total amount so sanctioned during the preceding year. The Board had no information as to the amount of the local loans which were contracted during the year without the sanction of any central department, but it might be stated that the total amount of the specific sums which by local Acts passed during the year were authorised to be raised by sanitary authorities and municipal corporations without the sanction of any central department was £1,496,287.

The Boarding-out of Pauper Children.

In reply to Mr. Norris, Mr. Ritchie stated that the initiative as regards the adoption of the boarding-out system rests with the boards of guardians, and not with the Local Government Board. The Board are always ready to entertain applications from guardians for the adoption of the system where the circumstances of the union appear to be such as to render that system appropriate, and provision has been made for complying with the requirements prescribed by the order of the Board.—Mr. Mundella asked whether the Local Government Board would undertake to extend the system of boarding out.—Mr. Ritchie said that the Local Government Board was always ready to consider any application for the extension of the system from boards of guardians.—Mr. Mundella asked whether the right hon. gentleman would promise to send circulars on the subject to the boards of guardians.—Mr. Ritchie replied that the Local Government Board had already caused the system to be thoroughly well known, but if necessary they would take further steps.

House-boats on the Thames.

On Thursday evening Colonel Dawnay asked the President of the Local Government Board whether his attention had been called to the proposed new bye-laws of the Thames Conservators, by which "no direct action will be taken to put a stop to the insanitary nuisances caused by house-boats and steam launches," and whether, in the interests of the millions of people who depend upon the Upper Thames for their water-supply, he will compel the Thames Conservators to take immediate and efficient steps to free the river from its present and ever-increasing state of pollution.—Mr. Ritchie said his attention had been called to the proposed bye-laws, and he had been in communication with the conservators of the River Thames on the subject. His hon. friend was incorrect in his assumption on the matter. The bye-law had intentionally been drawn as widely as possible in order to cover any possible pollution, and the conservators believed that when the bye-law came into operation it would have the effect of preventing the nuisance now arising from vessels moored in or navigating the river. He would, however, be happy to consider any suggestions relative to the bye-law.—Col. Dawnay gave notice that he would move a resolution on the subject.—Mr. H. H. Fowler asked if the legal advisers of the Local Government Board were satisfied that the bye-laws made by the Thames Conservators would in their present shape prohibit boats from discharging watercloset refuse into the river?—Mr. Ritchie: I have not considered it necessary to consult the legal advisers of the Local Government Board on the subject, but so far as I have been able to ascertain the opinion of the officials of the Local Government Board they believe that the bye-laws will have that effect.

MEDICAL TRIALS.

CITY OF LONDON COURT.

A MIDWIFERY CASE: DAWSON *versus* LANE.

THE plaintiff in this case stated that he was called at 8.30 A.M. on Oct. 3rd to defendant's wife, who was stated to be in labour. Believing it to be premature, and that no one was engaged to attend, he went at once. On arriving at the patient's house he found that another practitioner (who had been engaged, and sent for two hours before) had the conduct of the case. He therefore charged half-a-guinea for a "night visit." Defendant: It was not a night visit, but at half past eight in the morning. Plaintiff: Technically a "night visit," your worship. His Honour (to defendant): What have you to say? Defendant: He never did anything; why should I pay him? Judge: It does not matter; you called the doctor from his bed, and took him to your house, and you must pay the debt.

Judgment was given for plaintiff, with costs.

Obituary.

PROFESSOR BORODIN.

ON Feb. 28th, Dr. Alexander Porphyryevich Borodin, Professor of Organic Chemistry in the Military Medical Academy of St. Petersburg, died quite suddenly from cardiac paralysis, probably from embolism of highly diseased coronary arteries. He was born in 1834, and had held his professorship since 1864, having been twice reappointed for periods of five years. In his days of studentship the deceased Professor had distinguished himself in chemistry under the instruction and guidance of his teacher, Professor Zinin. His published works are tolerably numerous, and include papers on the analogy between phosphorous and arsenious acids from a toxicological point of view, on the estimation of salts in mineral waters, on brick tea, and a number of important articles on the estimation of nitrogen. By means of Professor Borodin's process combined with that of Kjeldahl, the clinical physician has now a means whereby this estimation may be made with a very moderate amount of difficulty and trouble. In spite of his arduous professorial and laboratory work, Professor Borodin found time for the cultivation of the art and science of music, in which he was quite an adept. He is, indeed, said to have rendered valuable service to the cause of music in Russia.

Medical News.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise on March 10th:—

Charlesworth, George, Elstead, Godalming, Surrey.
Down, Arthur Reed, Newton-square, Bampton, Devon.
Paterson, George Snider, Toronto, Canada.
Vinter, Sydney Garratt, Monmouth-road, Bayswater.

HOSPITAL SUNDAY collections were made at Middlesborough on the 6th inst.

A FAMILY, consisting of father, mother, and several children, at Grimsby, have been poisoned by eating tinned meat.

Digitized by Google

AT an inquest held at South Tottenham recently on the body of a boy, the jury returned a verdict of "Death from hydrophobia, caused by the bite of a cat."

GUY'S HOSPITAL.—The treasurer of Guy's Hospital, London, has received another anonymous donation of £500 towards the special fund.

MEDICAL MAGISTRATE.—The Lord Chancellor has added the name of Sir James Sawyer, M.D., to the Commission of the Peace for the borough of Birmingham.

TWO sons of the late Mr. Samuel Morley have each presented £2250 to the Deaconesses' Institution and Hospital, Tottenham, in order that the debt on the third wing of the hospital, lately built, may at once be cancelled.

THE date of the annual festival in aid of the funds of the Hospital for Sick Children, Great Ormond-street, has been altered from the 17th inst. to May 25th. The chair will be occupied by the Marquis of Ripon, K.G.

AT a public meeting at Portsmouth on the 3rd inst., it was resolved, amongst other plans for celebrating the Jubilee, to provide a fund for use in connexion with the Royal Portsmouth, Portsea, and Gosport Hospital.

PRESENTATION.—The members of the Leith police ambulance class have presented Mr. O. H. Garland with a handsome pair of silver candelabra, in recognition of his services as lecturer.

THE BRITISH ASSOCIATION will this year meet in Manchester, and the session will commence on Aug. 31st. Sir Henry Roscoe, M.P., F.R.S., has been chosen president. It is anticipated that the meeting will be one of the most successful ever held.

MANCHESTER SOUTHERN HOSPITAL.—At a meeting of the Board of this institution on the 28th ult., it was resolved that a lying-in hospital be formed in connexion with the hospital, and a sub-committee was appointed to give effect to the resolution.

THE East Sussex and West Hants Infirmary was reopened on the 8th inst., after having been closed in sections for three months during the renewal and remodelling of the sanitary arrangements of the building, at a cost of about £1000. The work has been designed and carried out by Mr. Mark Judge.

NOTTINGHAM BOROUGH ASYLUM.—An important extension of the Nottingham Borough Lunatic Asylum is about to be undertaken, whereby accommodation will be provided for 200 extra patients, the number at present in the building being 280. It is estimated that the work will cost nearly £30,000.

THE PROPOSED HOSPITAL AT BOURNEMOUTH.—At a largely attended meeting in Bournemouth on the 10th inst., it was announced that Mr. W. Clapcott Dean had offered a free site, valued at £1000, for the erection of the proposed public hospital. The subscriptions promised towards the building expenses amount to £3632.

AT the annual meeting of the subscribers to the Chesterfield and North Derbyshire Hospital on the 9th inst. it was reported that 217 patients had been admitted during the year, and that the dispensary patients had numbered 1851, as against 1983 in the previous year. The income amounted to £1848.

NORTH-WESTERN ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—At the usual monthly meeting of the members of this Association on the 10th inst. Dr. Sidebottom (Hyde) read a paper on "The Small-pox Epidemic in Hyde in 1886." A discussion, in which several members of the Association took part, followed the reading of the paper.

BEQUESTS.—The late Miss Hargreaves of Mellor, near Blackburn, has bequeathed the sum of £1000, less legacy duty, to the Blackburn and East Lancashire Infirmary. A residuary legacy has also been left to the institution by an East Lancashire gentleman recently deceased, but the exact amount has not yet been stated.

A MEETING convened by the London Tailors' Machinists' Society was held on the 12th inst., for the purpose of explaining and condemning the sweating system. Resolutions calling for a Royal Commission of Inquiry, and for the appointment of additional factory inspectors in East London, were carried.

AT the meeting of the Lambeth Board of Guardians on the 9th inst. the medical officer of the infirmary reported that there were seventy-five men and seven women in that institution in excess of the proper number of inmates.

UNIVERSITY OF CAMBRIDGE.—At Gonville and Caius College, Dr. Shuttleworth's Scholarship, of the annual value of £60, and tenable for three years, open to the competition of medical students of the University of not less than eight terms' standing, given for proficiency in botany and comparative anatomy, has been awarded to Francis Henry Edgeworth, B.A., scholar of the College.

OLEOMARGARINE.—A Bill regulating the importation, manufacture, and sale of butter substances has been brought into the House of Commons by Sir Richard Paget, M.P. for the Wells Division of Somerset. According to it, oleomargarine is to be sold only under its own name, the penalty incurred by infringement of this provision being £20 for the first offence, and £50 on subsequent occasions.

HEREFORD GENERAL INFIRMARY.—The annual general meeting of the governors of this charity was held on the 10th inst. The annual report, which was adopted, stated that the number of in-patients received during the year was 654, and of out-patients 2521. The receipts, inclusive of a balance in the hands of the treasurer of £667, amounted to £4915, and the expenditure to about £3000.

YORK EYE INSTITUTION.—On the 11th inst., at a meeting of the subscribers to this charity, it was decided to hand over the funds and property of the institution to the York County Hospital, on condition that Dr. Anderson be appointed ophthalmic surgeon, and that in-patients be admitted into the hospital by ordinary hospital recommendation, and out-patients be attended to without recommendation.

BELVIDERE HOSPITAL, GLASGOW.—This hospital, for infectious diseases, has just been completed, and was on the 4th inst. formally handed over to the care of the Health Committee of the Town Council. For small-pox patients there are five brick pavilions, comprising ten wards and containing 150 beds. Other infectious diseases are provided for by thirteen pavilions, with twenty-six wards and 390 beds. The hospital has cost £106,402, exclusive of the value of the site, which is an estate of thirty-three acres, situated on the banks of the Clyde, in the east-end of the city.

EXTENSIVE SEIZURE OF DECOMPOSED TINNED MILK.—At a late sitting of the Newcastle Police-court the sanitary inspector applied for an order for the destruction of 136 tins of condensed milk, which, according to the evidence of the medical officer of health, was in a state of decomposition. It is right to state that the tins were not branded with the name of the manufacturer, and in the opinion of Dr. Robinson the milk had been bad when packed. The order was at once granted. The use of condensed milk has very much increased in the north, especially in the winter, and, as a rule, it is found to be pure and economical.

BOLTON INFIRMARY AND DISPENSARY.—The annual meeting of the subscribers to this institution was held on the 10th inst., when the secretary reported that the average daily number of in-patients during the past year was seventy-two, the greatest number at one time being ninety-two, and the smallest number fifty. The total receipts for the year amounted to £5023, and the total expenditure to £5417. The committee appeal for additional annual subscriptions to enable them to provide fourteen more beds, for which there is room in the hospital, but which, through want of funds, it has hitherto been impossible to maintain.

ST. MARY'S HOSPITAL, MANCHESTER.—The annual general meeting of the subscribers to this charity was held on the 14th inst., when the secretary stated that the income for the past year had amounted to £3514, and the expenditure to £3862. The number of cases under treatment during 1886 was 15,098, as compared with 14,240 in 1885. It was resolved to appeal to the general public in Manchester, Salford, and surrounding district for funds necessary to provide for an extension of the present accommodation in the hospital, and a list of donations for this object amounting to about £10,000, which have been already promised, was read out.

Digitized by Google

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—The annual meeting of the governors of this hospital was held in the Medical Institute, Cleveland-road, on the 8th inst. The annual report stated that during the last year the number of in-patients had been 1956, and the number of out-patients 11,858. The income had been £6854 8s. 10d., and the expenditure £7116 12s. 2d. The Hospital Saturday contributions have amounted to £2182 0s. 5d., being a decrease of £30, and the Hospital Sunday collections to £578 15s., being a decrease of £76. The bequests received during the year have amounted, after deduction of legacy duties, to £1202 9s. 2d. The average stay in the hospital of each patient was twenty-four, days, as against twenty-two days last year. The number of patients sent to various convalescent homes has been 97.

SANITARY REGISTRATION OF BUILDINGS BILL.—At the meeting of the Council of the Sanitary Assurance Association, on March 14th, a communication was read from the Association of Municipal and Sanitary Engineers and Surveyors requesting the Council to convene a conference on the subject of the Sanitary Registration Bill, and, in the event of the request being acceded to, offering to co-operate in the matter. After some discussion, the following was passed unanimously:—"That, in compliance with the request of the Association of Municipal and Sanitary Engineers and Surveyors, a conference be convened to consider and report upon the principle and details of the Sanitary Registration of Buildings Bill which is now before the House of Commons; that the first meeting of the conference be held on Monday, April 4th, at 3 P.M.; that Sir Joseph Fayrer, Sir Kennett Barrington, Mr. Mark H. Judge, and Mr. H. Rutherfurd, barrister-at-law, be appointed to represent the Sanitary Assurance Association at the conference; that Mr. C. C. Lacaita, M.P., Dr. R. Farquharson, M.P., Sir Guyer Hunter, M.P., Dr. Charles Cameron, M.P., and Sir Henry E. Roscoe, M.P., be invited to attend the conference; and that the governing bodies of the following institutions be requested to appoint four gentlemen to represent them at the conference: The Royal Institute of British Architects, the Institution of Civil Engineers, the Royal Institute of Architects of Ireland, the London Sanitary Protection Association, the Society of Medical Practitioners registered as qualified in Sanitary Science, the Institution of Surveyors, the Association of Municipal and Sanitary Engineers and Surveyors, the Society of Medical Officers of Health, and the Sanitary Institute of Great Britain. Further, that the question of inviting other bodies to join in the conference be left in the hands of the conference."

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ARGO, ADAM, M.B., C.M.Aber., has been appointed Medical Officer for the Bridworth District of the Runcorn Union.

COLLINSON, F. W., M.B., C.M.Edin., M.R.C.S., has been appointed Senior House-Surgeon to the Preston and County of Lancaster Royal Infirmary, vice W. F. Moore, resigned.

FRASER, ANGUS, M.A., M.D., C.M. Aber., has been appointed Second Physician to the Aberdeen Royal Infirmary, vice Beveridge, deceased.

GOSTLING, T. P., M.R.C.S., L.R.C.P.Lond., L.S.A., late House-Surgeon, House-Physician and Obstetric Assistant to University College Hospital, London, has been appointed House-Surgeon to the General Infirmary, Worcester, vice J. Allman Powell, M.D., resigned.

GRIFFIN, ALBERT W., M.R.C.S., L.R.C.P.Ed., has been appointed Medical Officer for the First District of the Uckfield Union.

MACKIE, JOHN, M.D.Ed., L.R.C.S.Ed., has been appointed Medical Officer to the Brechin Local Authority, vice Lawrence, resigned.

MORIARTY, PATRICK HICKSON, L.R.C.S., L.R.C.P. Ed., has been appointed Medical Officer for the Listowel Union, and Medical Officer of Health, vice Rice, deceased.

MUDGE, THOMAS H. T., M.R.C.S., L.R.C.P.Lond., has been appointed Medical Officer for the Paignton District of the Totnes Union.

RODGER, JAMES, M.A., M.D., C.M.Aber., has been appointed Assistant Physician to the Aberdeen Royal Infirmary.

ROSS, RICHARD A., M.R.C.S., L.S.A., has been appointed Medical Officer for the Eighth District of the Bedminster Union.

SMITH, PATRICK BLAIKIE, M.D., C.M. Aber., has been appointed Third Physician to the Aberdeen Royal Infirmary, vice Fraser, promoted.

THOMPSON, WILLIAM C., L.K.Q.C.P.I., L.R.C.S.I., has been appointed Medical Officer for the West Drayton District of the Uxbridge Union.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

BETHLEM HOSPITAL.—Two Resident Medical Students who have recently obtained their diplomas to practise medicine and surgery. Apartments, rations, and attendance.

BURTON-ON-TRENT FRIENDLY SOCIETIES' MEDICAL ASSOCIATION.—Resident Surgeon.

CHELTENHAM GENERAL HOSPITAL.—House-Surgeon. Salary £80 per annum, with board and apartments.

CHILDREN'S HOSPITAL AND DISPENSARY, Manchester.—Medical Officer. Salary £180 per annum.

GENERAL HOSPITAL, Birmingham.—Resident Surgical Officer. Salary £130 per annum, with residence, board, and washing.

HUDDERSFIELD INFIRMARY.—Junior House-Surgeon. Salary £40 per annum, with board, lodging, and washing.

MACCLESFIELD GENERAL INFIRMARY.—Junior House-Surgeon. Salary £70 per annum, with board and residence in the Institution.

MANCHESTER ROYAL INFIRMARY.—Resident Medical Officer of the Convalescent Home at Cheadle. Salary £150 per annum, with board and residence.

OLDHAM INFIRMARY.—House-Surgeon. Salary £80 per annum.

OWENS COLLEGE, Manchester.—Senior Demonstrator in Physiology. Stipend £150 per annum.—Junior Demonstrator in Physiology. Stipend £100 per annum.

ROYAL FREE HOSPITAL, Gray's-inn-road.—Junior Resident Medical Officer. Board and residence are provided in the hospital.

ROYAL PORTSMOUTH, PORTSEA, AND GOSPORT HOSPITAL.—Assistant House-Surgeon. Salary, with board and residence, £60 per annum.

TOTTENHAM AND EDMONTON DISPENSARY.—Dispenser. Salary £50, plus £20 a year allowance for fuel and service, with house free.

YORK COUNTY HOSPITAL.—Assistant House-Surgeon. Salary £50 per annum, with board and residence.

Births, Marriages, and Deaths.

BIRTHS.

BALLANCE.—On the 11th inst., at 56, Harley-street, Cavendish-square, W., the wife of Charles A. Ballance, M.S., F.R.C.S., of a son.

NICHOLS.—On the 9th ult., at Nowgong, Bengal, the wife of Surgeon F. P. Nichols, M.B.Cantab., M.R.C.S., Army Med. Staff, of a daughter, who only survived her birth a few minutes.

OAKES.—On the 9th inst., at Merimbula, Priory-road, N.W., the wife of Dr. Arthur Oakes, of a daughter.

SMYTH.—On the 15th inst., at Holly Lodge, Brockley, S.E., the wife of F. Sydney Smyth, L.R.C.P., F.R.C.S.E., of a son.

STEWART.—On the 16th inst., at Glenharr, Mapperley-road, Nottingham, the wife of Donald Stewart, M.D., of a son.

WELLS.—On the 11th inst., at Cuckfield, Sussex, the wife of A. R. Wells, M.D., of a son.

MARRIAGES.

ELLIOTT—SLADE-GULLY.—On the 9th inst., at Chute, F. H. Elliott, M.D., to Eleanor Louisa, eldest daughter of the late Captain Slade-Gully, Bengal Staff Corps.

JOLLY—LESTER.—On the 10th inst., at St. Mary's Episcopal Church, Glasgow, Sydney Blake Jolly, M.B.Cantab., M.R.C.S., to Maude Helena, younger daughter of Wm. Lester, Esq., of Donne-terrace, Glasgow.

LOWNDS—IMRAY.—On the 16th inst., in the Chapel Royal, Savoy, by the Rev. Henry White, M.A., Chaplain of the Savoy, and Chaplain in Ordinary to the Queen, Henry Arthur Lownds, L.R.C.P., L.R.C.S., of Kirkburton, Yorks, to Ethel, daughter of John Imray, Esq., M.A., of Sedgemere, East Finchley.

ORR—WILKINSON.—On the 12th inst., at Granard Presbyterian Church, Putney, London, Wm. Young Orr, M.B.Ed., M.R.C.S., to Margaret, fourth daughter of the late Frederick Wilkinson, of Cleveland House, Barnes, S.W.

PRIESTLEY—JACQUES.—On the 12th inst., at the Parish Church, Streatham, S.W., Joseph Priestley, B.A., M.D., M.R.C.S., to Edith Blanche, youngest daughter of Edwin Jacques, M.D., of Fir-grove, Brixton, S.W.

DEATHS.

FLECK.—On the 14th inst., at Frogmoor Lodge, High Wycombe, Kathleen, only daughter of William Fleck, M.D. (of croup), aged 2 years.

FRANCIS.—On the 6th inst., at Brighton, Dayrell Joseph Thackwell Francis, M.D., F.R.C.P. Lond., of Wethersell Grange, Cranleigh, Surrey, aged 67.

GILLAND.—On the 8th inst., at Sevenoaks, Robert Bryce Gilland, M.D., late Medical Superintendent of Berks County Lunatic Asylum, Moulsford.

HARTLEY.—On the 10th inst., at Roxeth Lodge, Carshalton, Surrey, James Hartley, M.R.C.S.

MARKWICK.—On the 12th inst., at his residence, Ventnor-villas, West Brighton, Alfred Markwick, L.R.C.P., F.R.C.S. (late of Leinster-square, Bayswater), aged 64.

STUTTER.—On the 9th inst., at Wickhambrook, Newmarket, Suffolk, William Gaskoin Stutter, F.R.C.S., aged 71.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, March 21.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.
ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.
CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M; Thursday, 2.30.
ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesday, 2.30 P.M.
HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.
METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.
ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.
CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.
SOCIETY OF ARTS.—8 P.M. Prof. W. C. Unwin: Machines for Testing Materials, especially Iron and Steel (Cantor Lecture).
MEDICAL SOCIETY OF LONDON.—8.30 P.M. Mr. R. Brudenell Carter: A case of Swollen Optic Disc in which the Sheath of the Optic Nerve was excised behind the Eye.—Dr. Ralfe: Renal Calculus passed after the Use of Solvents.—Dr. Allchin: Case of Intussusception.—Mr. J. Astley Bloxam: Case of Congenital Malformation of the Diaphragm.

Tuesday, March 22.

GUY'S HOSPITAL.—Operations, 1.30 P.M. and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.
ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.
CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.
WESTMINSTER HOSPITAL.—Operations, 2 P.M.
WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 1.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M.
ROYAL INSTITUTION.—3 P.M. Prof. Gamgee: Function of Respiration.
ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. Broadbent: The Pulse (Croonian Lecture).
ANTHROPOLOGICAL INSTITUTE OF GREAT BRITAIN AND IRELAND.—8.30 P.M. Dr. H. Rink: On the Migrations of the Eskimo.—Mr. Coutts Trotter: Notes on the Inhabitants of the Polynesian Islands.—Lieut. F. Elton, R.N.: Extracts from Notes on Natives of the Solomon Islands.
ROYAL MEDICAL AND CHIRURGICAL SOCIETY.—8.30 P.M. Mr. Godlee: On a case of Obstruction of one Ureter by a Calculus, accompanied by Complete Suppression of Urine.—Mr. R. W. Parker: On a case of Suppression of Urine, following Injury to a Sacculated Kidney containing Calculi, the other kidney being entirely disorganised.—Dr. Warner and Dr. Fletcher Beach: A case of Chronic Meningitis, probably syphilitic, and causing Progressive Dementia.

Wednesday, March 23.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.
MIDDLESEX HOSPITAL.—Operations, 1 P.M.
ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.
ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.
LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.
GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.
SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.
UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.
ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.
KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.
CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M.; Saturday, same hour.
SOCIETY FOR THE ENCOURAGEMENT OF ARTS, MANUFACTURES, AND COMMERCE.—8 P.M. Dr. Percy Frankland: Some of the Conditions affecting the Distribution of Micro-Organisms in the Atmosphere.
HUNTERIAN SOCIETY.—8 P.M. Dr. Turner: Actinomycosis.—Dr. Dundas Grant: (1) A case of Caries of the Vertebræ from a Fish-bone in the Throat; (2) Laryngeal Growths; (3) Carcinoma of Œsophagus.
SOCIETY OF ARTS.—8 P.M. Dr. Percy Frankland: Some of the Conditions affecting the Distribution of Micro-organisms in the Atmosphere.
BRITISH GYNÆCOLOGICAL SOCIETY.—8.30 P.M. Specimens will be shown by Drs. Pearse, J. Mansell-Moullin, Bdls, and others.—Mr. Lawson Tait: Methods of Cleansing the Peritoneum. Council at 8 P.M.

Thursday, March 24.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Ophthalmic Operations, Friday, 1.30 P.M.
CHARING-CROSS HOSPITAL.—Operations, 2 P.M.
NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.
ROYAL INSTITUTION.—3 P.M. Prof. F. Max Müller: Science of Thought.
ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. Priestley: Pathology of Intra-uterine Death (Lumleian Lecture).

Friday, March 25.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.
SOCIETY OF ARTS.—8 P.M. Mr. Frederick Clifford: Indian Coffee.
CLINICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Davies Colley: On Contraction of the Metatarso-phalangeal Joint of the Great Toe.—Dr. Samuel West: Cases of Internal Suppuration, acute and chronic, without fever.—Mr. Treves: A Form of Glandular Swelling that is cured by Arsenic.—Mr. Parker and Dr. Robinson: Inherited Congenital Deformity of the Hands and Feet, Plastic Operation on the Feet.
ROYAL INSTITUTION.—9 P.M. The Right Hon. Lord Rayleigh: Colour of Thin Plates.

Saturday, March 26.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.
ROYAL INSTITUTION.—3 P.M. The Rt. Hon. Lord Rayleigh: On Sound.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

OBSTINATE CONSTIPATION IN INFANTS.

ON this subject *Whole Meal* writes that Dr. Simmonds (see THE LANCET, *ante*, p. 506) has "hit the right nail on the head" in his suggestion of the use of wheat bran for the constipation of infants. Our correspondent says he had been a martyr to both indigestion and constipation for years, but the sole use of whole meal as bread has entirely freed him from the pain and discomfort attending those affections.

L.R.C.P.—1. The nervous system of the patient should be thoroughly investigated. The positive pole should be placed at the back of the neck, and the negative moved about the forehead.—2. Perhaps the Secretary of the Royal College of Surgeons would give our correspondent the information he desires. It would obviously be unadvisable to publish the details referred to.

Dr. N. Whitelaw Bourns.—The qualifications are ample for the recovery of all reasonable medical and surgical charges.

M.R.C.S. will find the information he desires in Cates' Dictionary of General Biography (published by Longmans), under the heading "Roderic."

PROFESSIONAL ETIQUETTE.

To Editors of the THE LANCET.

SIRS,—Some time ago one of my patients was sick, and during her illness her mother went home to London. In London she consulted a physician about her daughter, and he gave her a prescription and actually sent out medicine, at least the medicine and the prescription duly arrived, though too late to be of any use, as my patient had quite recovered. This was, perhaps, fortunate, as the case was such as made it impossible for him to be sure of his diagnosis. But as yet there has been no word to me of excuse for the liberty that has been taken with my practice. As this is the second time such a thing has been done to me by London medical men, I would be glad to know if it is the usual custom, if it fulfils their idea of "doing to others as they would have others do unto them." The position of my patient being known to both, and being such that no time would pass before seeking medical aid in every case except the most trifling, neither can have the excuse of "not knowing that I was in attendance." Medical practice in Jerusalem is disagreeable enough, in all conscience, without being made so by conduct such as I have described. We number nineteen in Jerusalem, mostly all of different nationalities, and the jealousy of race is added to professional jealousy, and in consequence, we make a very unhappy family. I have not written to either of the gentlemen to whom I refer above, but probably they will know whom I mean when they see this letter in THE LANCET. It is not at all uncommon for tourists of our profession, especially in its middle grades, to give their advice here to patients who may seek it without ever inquiring, or ignoring that they were under treatment at the time.—Yours faithfully,

Jerusalem, Feb. 28th, 1887. JOHN H. OGILVIE.

Errata.—"J. B. Trap, Esq.," should have been J. B. *Trapp*, Esq., and "T. S. Marley, M.D.," should read T. S. *Morley*, M.D.

C. O'H.—It is usual to call medical evidence in such cases, but the coroner is not under any obligation to do so, especially when the cause of death is obvious.

Dr. M'Mordie's letter shall have attention.

REMARKS ON VACCINATION AND REVACCINATION.

To the Editors of THE LANCET.

SIRS,—In a society journal this week the following occurs:—"The illness of Prince Alexander of Battenburg has put the Darmstadt *ménage* in a very pretty fright, and vaccination has become a rage with Prince Alexander of Hesse's household, every soul of which has now a sore arm, which it takes him all his time to guard from injury. One lady, proud of her arms and unwilling to have their beauty marred by inoculation marks, wanted the operation to be performed on the calf of her leg. Her request was refused by the physician." Without entering into discussion on the above passage, I shall ask the question, Should a physician refuse to comply with the patient's request under similar circumstances? I say, No. I have for some years advised vaccination and revaccination on the thigh in preference to the arm or any other part. The position I prefer is the middle or lower third of the outside, in infants selecting the leg which is least likely to come in contact with the mother or nurse. I find the operation to be more easily performed here than on the arm; the surface is larger, smoother, and less apt to bleed, the arm being frequently congested at the time from the undressing of needlessly profuse and tight-fitting garments. In cold weather this situation has increased advantages. I have never had the vesicles injured afterwards. It is especially for women that the question of site is of so much importance, with their ever-eccentric tyrant, fashion; and never was fashion more unseemly and insanitary than the present style demanded by the etiquette of the Court!

I am, Sirs, yours faithfully,

Ladbroke-grove, W., March 11th, 1887. W. SINCLAIR THOMSON, M.D.

H. X.—No; there is no illegality in the operation *per se*. The duty of a medical man if consulted on such a question is quite clear. As a rule, he ought to discountenance the practice. It is, moreover, highly reprehensible, as offering an inducement to vice.

Puzzled.—The only reply we can make our correspondent is that made by Lord Bacon to so many of his own queries—*Fiat experimentum*.

Mr. G. Nelson has not enclosed his address.

THE TREATMENT OF PHTHISIS.

To the Editors of THE LANCET.

SIRS,—I see by THE LANCET of the 5th inst. that Professor Kremianski of Moscow has been endeavouring to effect the cure of phthisis (tuberculous) by means of atomised aniline. I may say that I have been for some time experimenting in the same direction, using a spray of solution of mercuric chloride ($HgCl_2$) of the strength of 1 in 5000. And so far as I have been able to judge, the results are decidedly promising, and likely to prove very satisfactory. I shall prepare a record of all cases which I may treat by this method (both successfully and unsuccessfully), and when the list is completed and arranged, I shall, if you consider the matter of sufficient importance, send the same to you for publication. I should have communicated with you regarding this subject before this, but thought it better to wait until fairly sure of my ground. The article above referred to in your last issue has induced me to ventilate the matter sooner than I had intended.

I am, Sirs, your obedient servant,

J. REYNOLDS, M.D. Brux., &c.

Cold Harbour-lane, Brixton, S.W., March 9th, 1887.

IMPROVED METHOD OF PACKING TINNED PROVISIONS.

IN view of the injury to health sometimes resulting from the ingestion of provisions secured in tin boxes, any intelligent attempt to avoid the possible dangers attendant upon that method of food preservation is to be commended. Such an attempt has been made by Mr. N. Ruffin, of Charlotte-street, Fitzroy-square, who has submitted to us specimens of tin cases in which the contents are kept from contact with the metal by means of a covering of muslin in the first place, followed by a coating of fat, and then by a layer of gelatine. This plan seems well calculated to effect the purpose intended.

G. Sheppard.—We understand that a proposal for giving the nursing in Indian hospitals into the charge of English ladies is now engaging the attention of the Indian authorities. Military nursing in England and in the Colonies is conducted by lady nurses who must have been trained before acceptance. Application should be made to the Director-General, Medical Department, Whitehall. Regarding other hospitals—to mention one or two,—the lady superior, All Saints, Margaret-street, would be able to give information about the Cape Town and, probably, many other colonial hospitals. The nursing at Kimberley is under the Bishop of Bloomfontein's Mission. There is a Greek hospital at Alexandria, where, we believe, English nurses are wanted. The superintendent might be communicated with. According to a letter in the *Hospital* for Nov. 20th, 1886, trained nurses are much valued and highly paid at the Philadelphia hospital.

N. L.—We certainly think that testimonials of the kind submitted to our notice are highly objectionable. But in this case, as in some others, evidence is wanting to show how far the testimonial-giver approves of the use made of his expression of opinion.

Dr. Elder.—The paper is marked for insertion.

STREET SEWER-VENTILATORS.

To the Editors of THE LANCET.

SIRS,—I would call attention to a very manifest possible cause of disease—i.e., the unprotected sewer ventilators which are generally placed in the centre of the road. The exhalations are not only unpleasant, but dangerous. I have myself suffered from them, and have attended patients who have similarly suffered (one died of intercurrent pneumonia after six weeks' illness). The symptoms are great feverishness, subsequently followed by exuviation of the mucous epithelium of the tongue and gullet (so that in swallowing there is a sensation as of burning, which extends to the stomach), inflammation of the tonsils, the gums (particularly) becoming inflamed, very painful, and spongy, and the teeth loosened in severe cases; where there are bad teeth or stumps inflammation of the periosteum occurs. I attribute this disease, which, in order well to fix its cause, I have called "gully-hole fever," to those ventilators from the fact that all my patients have lived close to one.

Of course, the ventilation ought to be conducted through hollow iron shafts, and drawn through this by means of burning gas-jets. Modifications of the Argand burner would be best, as the air would then have to pass through the flame, thoroughly destroying the germs by burning (as I suggested ten years ago as the resolution of the small-pox hospital difficulty). One advantage of this system is that the ventilation remains no longer passive, but becomes active, the vacuum formed by the heat drawing up the air forcibly, so that probably not more than one-tenth the present number of ventilators would be required. In addition, the shafts so arranged could be used as brilliant gas-lights.

I am, Sirs, yours obediently,

HENRY GODRICH, B.A., 1st B.Sc. Lond.

Long Ditton, March 9th, 1887.

PROVIDENT DISPENSARIES: THE WANDSWORTH MEDICAL AID SOCIETY.

IN answer to the letter on this subject from Dr. Nicholas, which appeared in our last issue, "A Grumbler," whose communication appeared on the 12th ult., states that he knows nothing of the promoters of the Wandsworth Medical Aid Society, nor of the place itself. He distinctly stated in his letter that he only took that particular society as a type, and contends that its promoters have really acknowledged the justice of his remarks, which were directed against the system of combination to obtain medical services at small fees.

A Recent M.R.C.S., L.R.C.P.—There is no basis for doing so, either in law or bye-laws.

Ambulator is referred to THE LANCET of March 12th, page 541.

MEDICAL PRACTICE IN THE WESTERN STATES.

To the Editors of THE LANCET.

SIRS,—I shall feel much obliged if any of your readers will give me some information about medical practice in Western America, especially in California and British Columbia. Are British diplomas fully recognised in both places? Is there a fair opening in either? And is the climate suitable for patients suffering from lung diseases? Can drugs be obtained easily there? Any other information will very much oblige.

Yours faithfully,

March 15th, 1887. A CONSTANT READER.

PLACENTA PRÆVIA.

As Dr. Murphy, in his letter published last week, intimates, there *is* a misprint in our article on the above subject. On page 479, second column, the commencement of the first paragraph should read as follows: "These accoucheurs treated *139* cases, with eight maternal deaths—a mortality of 4·3 per cent." It is hardly necessary to remark that the argument is not affected by the error.

Sister Jessie's lines are hardly of sufficient merit for our columns.

NITRITE OF AMYL: RELIEF OF AFTER-PAINS.

To the Editors of THE LANCET.

SIRS,—The following note may be found interesting to many of your readers.

A lady whom I had the day before delivered of a fine boy complained to me on my second visit of excruciating after-pains, which she declared were worse than any she had experienced during the labour. On examination I found the womb firmly contracted. Her loss was slight, and no clots larger than beans had been passed. As it was some distance from home, and several hours must necessarily have elapsed before I could have sent her any medicine, I broke a couple of nitrite of amyl capsules (four grains in each) into a smelling-bottle, and directed the patient to take two or three deep inhalations when she felt a pain coming on. The effect was simply magical; the pains were immediately relieved, and shortly ceased altogether, the patient being soon able to take some refreshing sleep. She quickly made an excellent recovery. I have since tried the same remedy in two other cases of less severity, with similar results. I have also found this useful drug invaluable in the sickness of pregnancy and in obstinate cases of dysmenorrhœa. I have hitherto not had a single failure or bad result. Inhalation seems to be more certain and lasting than the internal exhibition of the drug. To all who are called upon to prescribe for the above common ailments I can strongly recommend this simple and, in my hands, efficacious plan of treatment. I am, Sirs, yours truly,

South Molton, March 4th, 1887. F. WELLESLEY KENDLE, M.R.C.S.

CONSTIPATION.

To the Editors of THE LANCET.

SIRS,—I shall be glad if any of your readers can give me a hint as to the treatment of the following case: The patient, a lady aged twenty-two, has been suffering the last four months from obstinate constipation. All the usual remedies have been tried, but without success; and relief can now only be obtained by the use of enemata. I may add that the patient is about three months advanced in pregnancy, and there is nothing abnormal with the pelvic viscera.

I am, Sirs, yours faithfully,

March, 1887. A CONSTANT READER.

COLORADO.

To the Editors of THE LANCET.

SIRS,—In your issue of Feb. 19th "A Physician" asks for information relative to Colorado as a health resort. I have seen no replies to that request, and would therefore suggest that he refers to papers noted in the Medical Digest and Appendix, Section 676: 4.—Yours truly,

Boundary-road, N.W., March 11th, 1887. RICHD. NEALE, M.D. Lond.

Croonian Lectures
ON
THE PULSE.

Delivered at the Royal College of Physicians of London, March, 1887.

By W. H. BROADBENT, M.D., F.R.C.P.,
PHYSICIAN TO ST. MARY'S HOSPITAL, CONSULTING PHYSICIAN TO THE LONDON FEVER HOSPITAL, AND PRESIDENT OF THE CLINICAL SOCIETY.

LECTURE I.

MR. PRESIDENT AND GENTLEMEN,—The subject I have chosen for the lectures which I have the honour to deliver before you, if it is to be judged of by its importance to the medical man, is well worthy of the attention of the College. It is to the pulse that we look first of all for trustworthy information as to the condition of the patient who seeks our aid, and the knowledge obtained from it is a sort of foundation upon which is built up the opinion we form from the collective symptoms he exhibits and from the results of our physical examination. On the other hand, since the pulse has been the object of attentive examination on the part of every physician here, from the first moment of his entering upon the study of medicine up to the present time, and by countless generations of physicians from the time of Galen onwards, it may appear to be an act of presumption on my part to bring before the College a subject with which every Fellow is equally familiar with myself. I might reply to this that there has been a great reawakening of interest in the pulse; that new methods of study and of investigation have been brought to bear upon it; that greater precision has been introduced into the descriptive terminology of its variations. But the justification I would plead is simply this, that I have myself learnt much, and still find that I have much to learn, with regard to the pulse, with regard to the significance of the changes observed in it, and especially with regard to the indications for treatment to be obtained from it.

We examine habitually the pulse at the wrist, and at first sight it seems strange that the radial artery, which supplies merely the structures of a part of the hand, a few small bones with their articulations, a few muscles and tendons, the skin and the nerves distributed to it, should afford the varied and far-reaching knowledge we look for in the pulse. The hand is not essential to life; it contains no organ of any importance, and *a priori* it might have been supposed that the variations in the circulation of the blood in so small a member could have no significance. We know as a matter of observation, however, that the pulse of the wrist indicates the condition of the circulation generally, and on reflection it is seen that, as a branch of the great arterial system, it receives every impulse starting from the heart, and reveals the frequency and force of its beats; and not only this, but as fluid pressure is equal, or tends to become equal in all parts of a freely communicating system of tubes, it shows the degree of freedom of the general outflow through the capillaries as well as the kind of propulsion by the heart. The very fact that the hand has no special circulation of its own liable to extreme variations for functional purposes, such as, for example, those which occur in the salivary glands, makes the radial pulse a more trustworthy index of the general circulation.

A preliminary question, upon which a distinct understanding must be arrived at, is the following: The pulse, what is it; and what is the exact information it furnishes? Now, it is not, as is commonly understood, and as is explicitly stated in text-books of physiology, much read by our students, an expansion of the artery. This, at any rate, is not what we feel or what is recorded by the sphygmograph. A moment's reflection as to the volume of blood discharged by the left ventricle into the aorta, and a comparison of this with the capacity of the entire arterial system, will convince us that it is altogether inadequate to produce any expansion of the smaller arteries appreciable to the touch. The aorta and its primary branches are, it is true, dilated somewhat by the injected blood, but even in a vessel the size of the carotid it is difficult to measure the increase of diameter, so minute is it; whereas in the radial, in which it must be much less, the sphygmograph, if its trace were taken to indicate actual enlargement of the artery, would show it to be considerable. Nor is the pulse a sinuous movement of the artery in its bed from elongation, which throws it into curves. To feel the pulsation in an artery, or to take a sphygmographic trace, a certain degreee of pressure must be applied to the vessel, and, as is well known, there must be a bone behind it against which it can be compressed. What happens, then, is as follows: in the intervals between the pulsations, when the resistance by the contained blood is at its lowest, the tube of the artery is more or less flattened; then comes the so-called wave of blood propelled by the systole of the left ventricle, or, to speak more accurately, the liquid pressure in the vessel is increased, and this forces the artery back into the circular form. It is this change of shape from the flattened condition impressed upon the vessel by the finger, or by the sphygmographic lever, to the round cylindrical shape which it assumes under the distending force of the blood within it which constitutes for us the pulse. Such a pulsation can be felt on a large scale by placing the foot on the unyielding and unelastic leather hose of a fire-engine in action, or shown in a schema of the circulation with inelastic vessels. It is not, then, an increase in the diameter of the vessel, but an increase of the blood-pressure within it, created by the systole of the ventricle of the heart, which constitutes the pulse.

Another common misconception must be cleared up—namely, that the pulse signifies onward movement of the blood in the artery. Since a certain amount of blood is propelled into the aorta at each systole, it would seem, at first sight, that there must be a corresponding propulsion of blood along the vessel which is under the finger, and misapprehension has been carried so far that the pulse wave has been understood to mean the actual transport of the blood, and even to indicate the rapidity of such motion. Short of this, it is more commonly taken for granted that the rate of movement of the blood in the vessels is directly proportionate to the strength of the pulse—that a good strong pulse implies a vigorous rush through the capillaries, and a weak pulse a languid flow. The stream from a divided artery and the pulsatile jet seem to countenance this conclusion. It is, however, an erroneous idea; if the radial is compressed close to the hand, the pulsation above is not extinguished, but exaggerated, and when an artery is tied the pulsation up to the ligatured point is more vehement than before. Pulsation is thus no evidence of onward movement of the blood, and resistance in the arteries and capillaries will have *pro tanto* the effect of a ligature, hindering or even arresting the onward current; and there can be no doubt that peripheral obstruction does at times reach a point which almost stops the flow from the arteries to the veins, the pulse appearing to be all the stronger on this account; in fact, we infer the existence of obstruction in the cerebral circulation from the exaggerated carotid beat on that side. This is a consideration which, it seems to me, is not adequately borne in mind. I think it enters into the explanation of dropsy, and especially of the varying amount of dropsical effusion under apparently similar conditions, and that it also helps to clear up obscurities in the relation between circulatory conditions and head symptoms.

The pulse, then, indicates simply the degree and duration of increased pressure in the arterial system caused by the ventricular systole. There is a certain mean blood-pressure maintained by the elasticity of the large arteries, varying greatly in different individuals, which keeps up the flow through the capillaries, and the level of which is determined by the resistance in the capillaries and the amount of force stored up by the elastic walls of the large arteries. This pressure is lowered by the outflow through the capillaries into the veins, and is reinforced by the successive contractions of the left ventricle and the pulse marks, and indicates the minimum and the maximum pressures, with the gradation from one to the other. The term "tension," as applied to the pulse, means simply the degree of fluid pressure within the artery, putting its walls on the stretch. Distension might, perhaps, be more expressive than tension, if less exact and technical. With these preliminary observations we may proceed to consider the factors of the pulse.

There are three factors in the production of the pulse, and the influence of each on the variations observed in it must be understood. I shall not enter upon them minutely here,

Digitized by Google

but certain observations are necessary to a full comprehension of the effects which will be studied later. The three factors are—1. The action of the heart. 2. The elasticity of the great vessels. 3. The resistance in the arteries and capillaries. The heart determines unconditionally the frequency and regularity or irregularity of the pulse, and, with certain qualifications, its force or strength. The great vessels, acting as an elastic reservoir, convert the intermittent jet issuing from the ventricle into a more or less continuous stream, impressing at the same time certain characters upon the pulse, according as the elasticity of their walls is perfect or impaired, and according as they are kept fully distended or only slightly on the stretch. The capillaries and arterioles, by the varying resistance which they offer to the passage of blood through them, determine the character of the pulse, and influence materially the action of the heart. Each of these must be considered in some detail.

It has just been said that the heart determines absolutely the frequency of the pulse; and this is true, in so far that the number of beats of the pulse corresponds with the number of the heart-beats, except when a certain proportion of the latter are too weak to reach the wrist, or when very little blood enters the ventricle during its diastole; with the exception, again, of that curious modification of the heart's action, in which there are two heart-beats coupled together for every beat of the pulse. It must not be lost sight of, however, that resistance in the peripheral circulation reacts upon the rate of the heart's action, as well as upon its character, the frequency being increased as resistance is lessened, and *vice versâ*, subject, however, in both cases to the intervention of the nervous system. The rhythm as well as the rate of the pulse is determined by the heart, and the pulse, generally speaking, is regular or irregular, according as the action of the heart is regular or irregular. The pulse, however, may be made irregular, when the heart is acting regularly, by beats failing to reach the wrist, and irregularity of the heart's action may be greatly exaggerated in the pulse.

With regard to the strength or force of the pulse, again, this must be directly dependent upon the strength of the ventricular systole. The pulse cannot be strong or forcible when the heart's action is weak, and it will not, as a rule, be weak when the heart's action is vigorous. But the volume of blood discharged by the ventricle into the aorta is another element in the production of the pulse. If from any cause the ventricle is not properly filled, as may be the case when there is obstruction in the pulmonary circulation, or when the mitral orifice is greatly narrowed, or when the ventricle has not time to dilate, as may happen in palpitation, the systole will have little effect in increasing the pressure in the arterial system; and there may, under such circumstances, be powerful action of the heart with a feeble pulse. As will be seen, however, when the influence of peripheral resistance is discussed, the apparent strength of the pulse may not correspond with the energy of the ventricular contraction, even when the amount of blood propelled is normal, and tension, or the degree of distension of the arteries while it is maintained by the heart and is dependent upon the pressure supplied by the ventricular systole, is by no means proportionate to its vigour.

The principal effect of the large arteries is to act as an elastic reservoir, which converts the intermittent jet of blood which issues from the ventricle into a continuous stream. They are kept in a state of continual distension, which is increased momentarily by each ventricular systole, and runs down to some extent in the intervals, but never during life, to a point at which the elastic coats of the vessel cease to exercise some compression on its contained blood. The force of the heart is thus stored up and delivered out gradually in the form of a steady pressure, which keeps up an almost uniform flow through the vessels of the periphery. The regular current of blood sustained in this way is essential to the functional efficiency of the central nervous system.

But the elasticity of the great vessels is concerned in the production of the dicrotism of the pulse. The conditions favourable to its manifestation are low tension in the arteries and sharp contraction of the heart. When the outflow by the capillaries is rapid, the pressure in the aorta and great vessels will run down speedily during the cardiac diastole, and there will be a great and sudden rise with the systole. There being, moreover, comparatively little resistance to the blood entering the aorta from the ventricle, its systole takes place rapidly. The force of the systole is divided; there is, at the same time, a launching forwards of the column of blood, and an expansion of the great vessels laterally, their elastic coats not being on the stretch, and so yielding easily. A rebound follows, which starts along the arteries the dicrotic wave from the closed semilunar valves. When, on the other hand, the onward movement of the blood in the periphery is obstructed, the pressure in the great vessels cannot reduce itself, the aorta is distended and its coats are on the stretch, there is little room for the contents of the ventricle, and the exact converse of the effects above enumerated will hold. There will, in particular, be little or no dicrotic wave. In proportion as the distension is extreme, the condition obtaining in the arteries will resemble those which would be present in a system of inelastic tubes. When, from atheromatous or other senile changes, the aorta and its primary branches have lost their elasticity, the resemblance to a system of inelastic tubes is more complete, and the pulse curve not being modified resembles that of the ventricle.

Not less important than the action of the heart in its influence on the circulation of the blood, and even more important in the modifications it produces in the character of the pulse, is the resistance in the arterioles and capillaries. It is by their resistance in front and the force of the heart's action behind that the mean pressure in the arterial system is determined. If the outflow through the capillaries is free, then no amount of blood which the heart in a normal condition can pour into the arteries, and no degree of energy with which this is projected into the aorta, will maintain the general arterial pressure at a high point. It is possible that great frequency of the heart's action, with the discharge of a full volume of blood by each systole, may pour blood into the arteries more quickly than it can run off by the capillaries even when relaxed, in which case the pressure would rise; but this is a rare occurrence, except for brief periods in excitement or the early stage of effort. On the other hand, when the passage through the capillary network is obstructed, the blood is dammed back in the arteries, and the pressure within them is raised, it being understood always that the heart is capable of supplying the requisite force, which must, of course, be sufficient to overcome the peripheral obstruction and keep up some onward movement of the blood, or life would cease. This average or mean tension present is a most important part of the knowledge to be obtained from the pulse; it is measured by the degree of fulness and resistance in the artery between the beats; the variations in the character of the pulse contributing to an accurate estimate of it. It follows from theoretical considerations which need not be here discussed, and it is proved both by observation and experiment, that the higher the constant or mean pressure in the arteries, the less is the difference between the maximum and minimum; or, in other words, the more full and firm the artery is between the beat, the less marked will be the pulse, and, *vice versâ*, the lower the tension and the more conspicuous the pulsation. The significance, again, of the constant or mean and the variable or pulsatile pressure is different. The mean pressure tells most with regard to circulation and the circulatory system. The variable pressure or pulse tells most with regard to the general state of the individual. These variations in the pulse, and the way in which they are produced by changes in the arteries and capillaries, must now be considered.

When the peripheral vessels oppose little resistance to the passage of the blood through them, the pressure in the arteries will not only be low, but it will also be variable. It will rapidly run down in the intervals of the ventricular systole and rise suddenly with each systole. This would be the case even were the rapidity of the individual contraction constant, and uninfluenced by the amount of force to be overcome; such, however, is not the case, for with diminished resistance the ventricle expels its contents more rapidly. The pulse, then, will be more sudden or sharp, and will seem to be more vehement. The artery at the wrist and elsewhere will allow itself to be flattened more easily and completely, as there is little pressure of blood within it to resist the external pressure; it is then suddenly distended and resumes its cylindrical form, repelling the finger and jerking up the sphygmographic lever. This effect is all the more marked from the fact that the walls of the artery will be relaxed and its diameter increased.

The converse effect will be produced by peripheral resistance. With a higher mean pressure the variations will be

Digitized by Google

less, and the rise of pressure, which constitutes the pulse, more gradual; this difference being accentuated when the artery is contracted. But another consequence flows from the varying resistance in the peripheral arterioles and capillaries. A given volume of liquid will pass more rapidly through a large channel than through a smaller under the same pressure. When, then, the resistance in the periphery is weak—which is equivalent to the channel being larger—the pulse will be short; that is, the wave is sudden and soon over, and, conversely, it will be long when the resistance is considerable. It is easy to confound the fulness of the artery between the beats with a prolonged beat; but, although these two conditions are often met with together, they are distinct, and must be kept so in our minds.

The sphygmograph has been invaluable in research; it has given precision to our ideas, and, in the hands of Marey and others, has made clear and comprehensible many intricate and doubtful problems of the circulation. It is capable, too, of rendering important aid in clinical investigation, especially where demonstration and records of changes in the circulation are required. To me personally the sphygmograph has been of immense service. I worked with it under the eye of Sibson, and shared Anstie's enthusiasm with regard to it when he and Professor Burdon Sanderson took up the instrument with which Marey endowed medical science. It is not, therefore, from ignorance of or want of familiarity with the sphygmograph that I have come to the conclusion that it is not specially useful in practice—that in any form known to me it is not a clinical instrument for every-day work. It is rarely necessary for diagnosis, and scarcely ever to be trusted in prognosis. The indications obtained from it are not, like those of the thermometer, independent of the observer. Skill and practice are required in applying it, judgment is called for in determining the position and pressure which give the best trace, and, indeed, in deciding which of the traces obtainable is the best representative of the particular pulse; the personal equation of the observer therefore comes in, and if any special result is greatly desired, an enthusiastic investigator can obtain it, and may without the least conscious intention twist facts in the required direction. It is necessary, also, before a trace can be interpreted with any degree of confidence, to know what form of sphygmograph has been employed. Marey's is still, in my opinion, the best, and his traces appear to me to correspond most closely with traces taken without instrumental multiplication and magnified by the lens. English modifications of Marey's sphygmograph often magnify the pulsation too much, and in doing so introduce exaggerations due to the rapid movement of the writing lever. Pond's and Dudgeon's instruments are extremely handy and convenient, but a gratuitous provision for exaggerations and for extraneous jerks and vibrations exists in the loose and unmechanical way in which the motion of the intermediate lever is communicated to the writing lever and in the weight which acts as counterpoise in the last-named lever.

The pretence, again, to measure the exact pressure employed in taking the trace, and thereby to obtain corresponding knowledge of the intra-arterial pressure, is illusory. To say nothing of the varying thickness and resistance of the skin, which would of itself vitiate all conclusions of this kind in at least three ways—by difference of flexibility, by affecting the position of the spring, and by varying the area of the button or pad actually in contact with the skin,—the size of the artery would introduce an element of uncertainty. Hydraulic pressure is equal at every point of the containing surface, and its force is multiplied by increase of area; the greater surface, therefore, of a large vessel would exercise greater lifting power, so that the same blood-pressure would appear to be higher or lower according to the diameter of the artery. For the same reason buttons or pads of different size resting on the vessel would affect the degree of force required in order to compress it, as would slight differences of adjustment. A knife-edge resting transversely across the vessel eliminates some of these uncertainties, and gives a more accurate trace, but requires delicate adjustment of the strength of the spring. The above would be true if the pressure exercised by the spring were accurately graduated; but this is far from being the case in any sphygmograph known to me, and graduation by the eccentric commonly employed is ridiculously inexact. While, then, I think that every student ought to be familiar with [illegible] sphygmograph, and will gain from a study of its [illegible] of the pulse in its different forms obtainable in no other way, I am of opinion that we learn by means of the educated finger all that the sphygmograph can teach, and more. It is invaluable as a means of educating the sense of touch, and of cultivating the faculty of observation; it is most useful in resolving doubts as to the difference between the pulse of the two sides in some cases of aneurysm, and in recording pulses in the graphic form; but it is not an infallible court of appeal, and there are niceties of information which are out of its reach. I need only point to the groups of pulse-tracings exhibited, which are by experts, to show that a sphygmogram does not speak for itself, but requires interpretation. One set is a series of normal traces made for me by the late Dr. Mahomed to illustrate my lectures at St. Mary's; the other is a copy from Marey's pulse of aortic regurgitation.

In examining the pulse our object is to obtain the most complete and exact knowledge attainable as to the circulation, and to interpret accurately the facts we observe, and I must be the more careful in describing the method to be followed, as I do not propose to refer to the sphygmograph. The point first noted is the frequency, the number of beats per minute and the regularity or irregularity of the beats, with regard to time, and their equality or inequality in force. This is simple and easy. We should naturally wish, in the next place, to estimate the force or strength of the pulse, but, considerations which modify the idea derived from the impression made on the fingers may first be conveniently discussed. It will be well, therefore, after counting the pulse, to give attention to the size of the artery. This varies greatly in different individuals, and may differ in the two wrists of the same person. It varies, again, greatly according as the muscular coat is relaxed or contracted. We have, then, to distinguish between congenital differences in the diameter of the vessels and variations induced by physiological or pathological influences. Now a large artery will communicate a more perceptible impression to the fingers placed lightly upon it than a small one, and the beat will seem more forcible. On the other hand, the pulse wave can usually be arrested more readily by pressure in a large artery, and the pulse is more compressible; one mode of examination thus controls or corrects the other. When the artery is small, and especially when it is rendered small by contraction of its muscular coat, there appears to be little pulsation in it, and the pulse may easily be set down as weak; but let an attempt be made to obliterate it by compression, and it often seems as if the pulse grew stronger as the pressure on the vessel increased.

An important point to be investigated is the degree of constant pressure prevailing in the arteries. The constant intra-arterial pressure, or pulse tension, is determined first by rolling the artery transversely under the three fingers, or endeavouring to do so. In a pulse of average tension, the vessel only stands out so as to be felt distinctly during the actual beat, and subsides gradually or rapidly in the interval; it cannot, therefore, be rolled by the fingers at all periods, though it may generally be distinguished with care, even between the beats, especially when the skin is thin and flexible. In a pulse of low tension the vessel can scarcely be said to be felt as such at all; it starts up with the beat, and is at once lost again when the brief wave has passed. In a pulse of high tension, on the other hand, the artery stands out among the structures of the wrist like another tendon, and can be rolled like a cord under the fingers, and followed often half-way up the forearm. While the vessel is thus being rolled about, the pulsation in it may scarcely make itself felt, and the artery can often be seen distinctly, if the skin is thin, projecting on the surface without any appearance of pulsation, except where it is thrown into curves. Pressure, however, brings out the pulsation and develops its force.

The character of the beat is another matter for study; and, brief as is the period occupied by it, each pulse-wave presents a rise, duration, and fall. It may strike the finger suddenly, or lift it deliberately; the distension of the artery may be momentary only, or it may persist for a time; the fall of pressure finally may be abrupt or gradual. For the most part, a sudden rise, brief duration, and abrupt fall go together, and constitute the short pulse of large arteries and low tension; while a gradual rise, persistent fulness, and slow decline are usually associated, and give the long pulse of contracted arteries and high tension. Exceptions, however, occur, and they are often of great significance. There may be a large vessel and sudden pulse when the tension is relatively high with dilatation of the left ventricle, and a

Digitized by Google

small artery, slowly and feebly filled, in extreme low tension with cardiac weakness.

We are now prepared to estimate the strength of the pulse. Three fingers are placed on the vessel, as is supposed to be the case from first to last. With that nearest the heart, pressure is made till the wave is arrested, so as not to be felt by the other fingers, or, if necessary, two fingers are employed to extinguish the pulsation. In this way, by the degree of pressure required, and by varying the pressure with one, two, or all three fingers, an idea is obtained of the force with which the heart is propelling the blood onwards. Account will have been taken already of the size of the vessel, and the method of noting the tension will have brought out other points which enter into consideration.

I have spoken of the manœuvre of rolling the vessel transversely under the fingers as a means of estimating the pressure and tension by which it is maintained in the cylindrical form. Another manœuvre by which the state of the coats of the artery is ascertained is to carry the skin along it longitudinally with varying pressure; curves in its course and bulging in its walls are thus detected; inequalities of thickness and density in the coats are felt, sometimes mere thickening and hardening, at others actual patches of rigidity and calcareous deposit; or the entire vessel may be found to have a thick, leathery, inelastic feel, or may be converted into an irregular, hard, calcareous tube, or may feel like a string of beads under the finger.

One more question of observation must be taken up—the recognition of dicrotism. For this purpose the fingers must rest as lightly as possible on the vessel, and uniform gentle pressure must then be made by all three. The dicrotic wave, when well within physiological limits of variation, will be felt like an echo of the principal beat, and when well marked is extremely distinct. A complete account of the pulse then should specify (1) the frequency—that is, the number of beats per minute, with a note of any irregularity or intermission or instability of the rhythm; (2) the size of the vessel; (3) the degree of distension of the artery between the beats; (4) the character of the pulsation, whether its access is sudden or gradual, its duration short or long, its subsidence abrupt or slow, note being taken of dicrotism when present; (5) the force or strength of both, the constant and variable pressure within the artery, as measured by its compressibility; (6) the state of the arterial walls. How far the description of the pulse usually given, even in cases in which much turns upon it, falls short of these requirements it is unnecessary to state.

It is impossible to examine with attention a large number of pulses, whether among the healthy or sick, without being struck by the extraordinary diversity of frequency, size, character, tension, and force met with. This diversity prevails quite independently of disease, in both sexes and at all ages, especially with regard to diameter of vessel and tension and force of pulse. If we judged only according to the size of the blood-channels, together with the pressure within them, we should be compelled to estimate the amount of blood flowing through the arterial system as three or four times as much in some persons as in others. But the amount of blood actually put in circulation is determined by the volume of blood discharged at each systole, and the number of contractions a minute, and assuming that the ventricles empty themselves at each contraction, there is no such difference in the capacity of the ventricle or in the rate of the heart's action as would corroborate the above estimate. Still, taking everything into account, there must, when we compare the small, short, compressible pulse of one man with the large, firm, and long pulse of another, be great differences in the rate and energy of the movement of blood through the capillaries in different individuals, and clearly there are great differences in the circulation of the same person at different times. The fact that such differences are compatible with health and vigour is conclusive evidence that nutrition and functional efficiency, even of the nerve centres, are not in such close relation with and intimate dependence upon the blood-supply as we are sometimes apt to suppose; and additional evidence, pointing in the same direction, is furnished by certain cases of valvular disease of the heart, as, for example, mitral stenosis, and of such functional derangements, for example, as that in which the pulse-rate is only 35 or 40 a minute, and there are two beats of the heart to one of the pulse, which still render the transit of blood through the heart more slow. There must, in effect, be provision for a very large margin of excess beyond the minimum blood-supply required for the purposes of the tissues and organs generally. It is a noteworthy fact, too, that in acute disease, which is attended with weakness and wasting, the circulation of the blood is accelerated, as is indicated by the larger diameter of the vessels and the increased frequency of the heart's action.

I have not been able to connect differences in the circulation with any constant bodily or mental character. A marked tendency to obesity appears usually to be associated with small arteries and low tension; and the thin wiry individual commonly has large arteries, which are conspicuous, not only from the thinness of the skin and absence of subcutaneous connective tissue, but also because, together with their size, they are markedly full between the beats. People with low arterial tension seem to wear out less quickly, and to furnish most of the examples of longevity; but they appear to have less power of resistance in acute disease. These, however, are given as mere impressions. Speaking generally, I have found physical strength, energy, and endurance impartially associated with small low tension pulse, and with large arteries and high tension, and the reverse. I can say the same of intellect, perseverance, courage, and force of character generally; they appear to be absolutely independent of circulatory conditions. It is, indeed, clear that the circulation is not the determining influence in the production of the differences which are found to exist in respect of bodily or mental energy. The circulation is the servant, and not the master; and, physiologically, it is tissue activity which conditions the blood-supply, and not the blood-supply which conditions the tissue changes. In disease, again, the modifications of the circulation which are observed are far more frequently effects than causes, and the pulse is an index not so much of a more or less rapid movement of the blood, to be taken into account as a factor in the morbid processes, as of the state of the nervous system and of the body generally which has determined its rate and character.

It would be impossible to discuss systematically all the indications afforded by the pulse in the course of these lectures, and it would be most undesirable to attempt it. Many of them do not depend upon a comprehension of the circulatory conditions which the varieties of pulse denote, or, indeed, upon a knowledge of the circulation at all. Observant physicians before the time of Harvey could gauge thoroughly the state of the patient in fever from the pulse, and it is not for the purpose of estimating the movement of the blood that we ourselves in a case of fever count the beats and note their force and volume. We calculate from the data thus obtained the strength of the sufferer and the effect upon him of the disease; and we might or might not do this more accurately than our predecessors. On the other hand, it is only through a knowledge of the conditions which govern the circulation that such facts as the connexion between kidney disease and cerebral hæmorrhage can be understood, and that the prognostic significance of the hard pulse which betrays this connexion can be appreciated. The ordinary diagnostic and prognostic indications of the pulse, then, which are learnt only by experience, and which would gain nothing by exposition in lectures, will not be considered, and I shall take up only such points with regard to the pulse as illustrate either effects of circulatory derangements or advances in our knowledge obtained by the more profound investigations of recent years.

I propose, then, to consider, first, deviations from normal frequency and abnormalities of the rhythm, which I hope to dispose of in this lecture; next, variations of tension, their causes and consequences, and the indications for treatment which they furnish—these, with perhaps the pulse of heart disease, will occupy the second lecture; the subject of the third will be the pulse and cerebral affections.

Frequency.—The rate of the heart's action, with which the frequency of the pulse corresponds, is governed by various influences. Resistance to the onward current of blood in the arteries, or, in other words, increase of pressure in the arterial system, whether produced by compression of large vessels, such as the femorals and brachials, or by obstruction in the arterioles and capillaries, tends to slow the action of the heart and render the pulse less frequent, and, conversely, diminished resistance or lowered tension accelerates the heart and pulse rate. But more direct and powerful than these varieties of the arterial pressure, and entirely overruling their tendency, are nervous influences, of which the channels are the pneumogastric and sympathetic nerves. It is not my intention to enter at all upon a discussion or

Digitized by Google

explanation of the respective action of these nerves; this would help us very little clinically, and knowledge with regard to them has not yet reached a perfectly stable condition. The question, too, is rendered complex by the fact that nervous influences reach the arterioles and capillaries as well as the heart, and modify the outflow of blood and the arterial tension; and an effect upon the heart, apparently direct, may be brought about indirectly through variations in the degree or resistance in the circulation. Almost all departures from a normal state of health are attended by increased frequency of the pulse, and it would serve no useful purpose to enumerate and attempt to classify the causes of pulse frequency, while its prognostic indications are so varied and delicate that they would elude description. They are, besides, among those matters of experience which are independent of scientific investigation, and are excluded under the rule which I have taken for my guidance. There are, however, cases in which frequency of the pulse, or rather of the heart's action, constitutes in itself the disease, or if not actually the disease, yet at least a source of danger and suffering. Such frequency is one form of palpitation of the heart. The fugitive attacks of hurried and violent action of the heart, induced by indigestion or emotion or over-exertion, need not occupy our attention; and I shall not do more than allude to the persistent frequency of the pulse in Graves' disease, or in hysterical conditions, or associated with aortic pulsation.

Persistent frequency of pulse.—Persistent frequency of pulse is one of the consequences of over-strain of the heart by exertion. It is met with in young men who have over-taxed their powers in rowing, training for races, or heavy gun drill; and was observed on a large scale in the American war. The name "irritable heart" employed as a descriptive term may very well be accepted. Besides the beating of the heart of which the patient is conscious, there are breathlessness on exertion, nervousness, depression of spirits and anxiety, sensations of faintness, sleeplessness, and incapacity for sustained exertion. In all the cases of this kind which I have seen, the pulse tension has been high. The great remedy for this condition is rest, and from one to three weeks in bed, however irksome and wearisome at this period of life, may be well spent in allowing the heart to settle down. During and after middle age, persistent frequency of pulse may be induced by a single act of excessive exertion, such as running to catch a train. The effects upon the heart of such an imprudence vary; there may be dilatation of the heart, with or without insufficiency of the mitral valve, or a valve may be actually damaged, or the action of the heart may become irregular; but, besides these, it may become hurried without irregularity, and the frequency may persist till the strength of the patient is worn out. Here, again, the arterial tension is, according to my experience, high, spasm of the peripheral vessels contributing to the effect, so that the distension of the arteries is not simply the result of blood being driven into the arterial system in consequence of the increased frequency of the heart's contractions. No satisfactory explanation has been given of these cases, and I have none to offer. Perhaps the most plausible is that the plex of minute nerve-ganglia and network of fibres so copiously distributed beneath the endocardium may have been stretched and rendered unduly irritable.

Paroxysmal palpitation.—It is late in life that paroxysmal palpitation with frequency of pulse is most commonly a cause of suffering and danger, shortening life and rendering it miserable. It may complicate heart disease of any kind, and may possibly sometimes be one of the consequences of the disease, but it may occur independently of valvular affection or of any structural change sufficiently advanced for recognition, and it has seemed to me that when disease of the heart is present the palpitation is often rather a complication than a consequence. The exciting cause may be indigestion and flatulence, or the mere act of taking food, lying down, emotion, apprehension of an attack at a particular hour or under given circumstances associated with former attacks; but, whatever this may be, the onset of the paroxysm is frequently accompanied by a sudden relaxation of the arteries, and the palpitation seems to resemble the excited action of the heart set up by nitrite of amyl or nitro-glycerine. Resistance to which it is habituated is suddenly removed, and the heart starts off like the engine of a locomotive when the wheels fail to bite the rails. In the course of a prolonged attendance upon a medical man advanced in years and long subject to gout, who suffered greatly from palpitation, this occurred more than once; when my hand was on the pulse the artery became large and soft, there was a flutter of the heart, which then bounded off. A remarkable complication occurred in this case which is worthy of being related. Early one morning the patient began to bring up bloody fluid from the lungs, and in the course of twenty-four hours expectorated several pints of it. A pink froth covered the bright-red liquid to the depth of half an inch, and the whole looked very much like the boiling red-currant juice in the process of making jelly. There was no rise of temperature, the flux of blood-stained serum gradually ceased, and palpitation did not recur for several months, when, after imprudent fatigue and exposure, it returned, and ultimately wore out the patient. It should be added that there was no valvular disease, and only moderate dilatation and hypertrophy with old-standing high arterial tension.

There still remains for notice the extraordinary rapid action of the heart, which can only be referred to some neurotic condition, lasting for days or weeks or months, of which numerous examples are on record. One of the most remarkable is that recently brought before the Neurological Society by Dr. Bristowe, to whom I am indebted for the following particulars: The patient was nineteen years of age, and there was reason to think that the affection dated from the age of eight, the attacks of rapid action of the heart recurring from time to time. When he entered St. Thomas's Hospital, he was suffering from anasarca and pulmonary apoplexy, which had supervened in the course of an attack which had lasted some months. The pulse varied, but often numbered 200 or 240. Under the influence of iron and digitalis, the action of the heart quieted down to about the normal, but was easily excited, and during one visit to the hospital the beats were counted at the rate of 304 or 308 a minute. He had resumed work as a draper's assistant, and on Feb. 26th was at work till midnight. Next morning he did not seem much the worse for it, but at midday, while playing the piano, he suddenly stopped and fell down dead. The heart was somewhat enlarged and dilated, but the valves were normal, and no other disease was discovered.

For particulars of another interesting case, with post-mortem examination, I am indebted to Dr. Dreschfeld and Dr. R. Maguire. The patient, a labourer, aged thirty-six, who had had syphilis and had been a heavy drinker, had suffered, when first seen in October, 1883, from attacks of palpitation for twelve months, which came on suddenly after a heavy supper, and were attended with vomiting, and usually lasted from fourteen to twenty days. The pulse rate was found to be from 215 to 230. No cardiac or other disease was discoverable. He improved under digitalis, the pulse falling rapidly to 86. He was again seen in December, 1883, and March, 1884, with relapse of palpitation and a pulse of from 200 to 215. On this last occasion, while under treatment by convallaria, he died in an attack of convulsions. The heart was large, and its structure presented degenerative changes, but nothing was found which could explain the rapid heart action.

Several cases have come under my observation in hospital or in consultation of which the course and sequel have not been known to me. In one seen with Mr. Stanley Smith in the course of last year, the patient, a lady aged sixty-four, died after seventeen days' illness, during which the pulse ranged from 150 to 200, the heart being apparently worn out. In one case I saw the patient, a lady of about forty-five, almost daily for about three weeks. The pulse was never under 200, usually 240, and there was every reason to believe that the heart was beating at the same rate during the whole of the time. The artery was small, full between the beats, not easily compressible, and the pulsation felt more like a vibration than a beat, and gave the impression of there being little or no onward propulsion of the blood. The heart sounds were short and equi-distant, and reminded me of the puffing of a distant locomotive. There was no opportunity of examining the pulse or heart during sleep, but the sleep was broken, and the feelings attendant on the palpitation were always present. This was a second attack after an interval of some years. I saw her in the first, which lasted about five days, and left her looking old and worn. She survived the second for at least two years, since which time I have not heard of her.

Another case was brought to me by Dr. Slocombe, in April, 1886. The patient, a gentleman aged fifty-six, was stout, and had a good colour, had lived freely in all respects, and worked hard. He had been suffering from palpitation night and day for three weeks, sleeping for two hours only, and

Digitized by Google

then restless all night. The pulse was 160, and had the character described in the last case. [A trace was here shown.] There was a reduplication of the second sound of the heart, best heard near the apex. The liver and spleen were large. Three weeks later the patient still looked extremely well, and his appetite was good, but he was subject to feelings of suffocation, during which he flushed, and his eyes had an expression of distress; these were brought on by very slight exertion or by stooping. He refused to consider himself an invalid, and went about much as usual. He could lie in any position, but when on his left side required a pillow under the side. He usually slept till 3 A.M., and then woke up suddenly. The palpitation had never ceased; the pulse was always 160; the heart was not much enlarged, the sounds equi-distant, the aortic second having a ringing note at the right second space; slight jugular pulsation was visible on the right side, and the liver was large; crepitation was heard in both lungs posteriorly, as high as the angle of the scapula. In June, when seen again, the palpitation continued, having lasted now three months. He had been out of town, and looked as well as ever, but evidences of stasis in the circulation had made their appearance, the legs had suddenly swollen, he could not lie down, and the liver was extremely large. The pulse was still 160; the heart beats as before, equidistant. Various lines of treatment had been tried without effect, and digitalis seemed to do harm. I have not seen the patient since, but I learn from Dr. Seccombe that he continued to suffer very much until November, when improvement began, and the patient was recently said to be so much better as to wish to resume his official duties. A later account, however, describes him as having had an attack of hemiplegia. This rapid action of the heart is, so far as I know, unexplained, except by referring it to some obscure neurotic influence. It is met with almost at all ages (Dr. Bristowe's patient appears to have been subject to it from the age of eight, and died of it at nineteen, and I have seen it in a child of ten), although it is more common after middle life than before; usually there is some apparent exciting cause, such as would put stress upon the heart; overwork and anxiety are the most common, but the predisposition, which is of more consequence, eludes us; sooner or later sudden death is the result.

It is interesting to speculate on the condition of the circulation. Clearly it is not accelerated, and the dropsy in Dr. Bristowe's and Dr. Seccombe's cases show that the tendency is to stasis. The pulse, too, gives one the idea of vibratory alternations of pressure with little onward movement. The question then arises, What is the condition of the left ventricle? Either it does not fill in diastole, or it fails to empty itself on systole. It may be that in some cases it is contracted, and refuses to dilate to receive blood from the auricle, and that in others it is in a state of over-distension; but it seems to me that the former is the more probable condition. I have usually found the heart of normal size, whereas persistent distension would sooner or later give rise to dilatation. Again, the cardiac impulse is often extremely powerful—I have seen the stethoscope lifted through a woman's stays—and this is inconsistent with over-distension. It might be asked, again, whether the peripheral arterioles and capillaries played any part in the phenomenon, or the pulmonary circulation? These are questions which I am unable to answer, and it is a satisfaction to me to know that the subject is engaging the attention of Dr. Bristowe.

A CREMATION CONGRESS.—It is intended to hold an International Congress on Cremation in September of the present year, the place selected for the gathering being Milan. French will be the official language, but the speakers may, if they like, make use of any other language. Reports will be submitted as to the progress made in the practice of cremation in different countries, and the formation of an international league will be proposed. An exhibition of models of crematories, urns, and other objects connected with the campaign now being conducted against the present methods of disposing of the dead will be open during the congress.

MR. T. M'LEAN has already opened his spring exhibition of oil paintings in the Haymarket. The collection is of the usual cosmopolitan character, and contains some sixty pictures, of which a "Foraging Party" of wild boars by Rosa Bonheur and Sir John Millais' "Fern Gatherer" will probably command most attention.

Gulstonian Lectures
ON THE
NATURE OF FEVER.

Delivered at the Royal College of Physicians,

BY D. MACALISTER, M.A., M.D., F.R.C.P.,
PHYSICIAN TO ADDENBROOKE'S HOSPITAL, LECTURER IN MEDICINE AT THE UNIVERSITY OF CAMBRIDGE.

LECTURE III.

MR. PRESIDENT AND GENTLEMEN,—In the last lecture I gave at some length my reasons for believing that the thermogenic function of the skeletal muscles, the chief sources of heat in health and in disease, is dependent on their innervation. I spoke of this innervation as twofold, corresponding to the motor and inhibitory innervation of the vascular and visceral muscles and of the heart. From the point of view of the chemical changes which take place in thermogenesis, I spoke of the nerves concerned as respectively catabolic and anabolic. The latter nerves were inhibitory of heat production, inasmuch as their influence is towards the upbuilding of the hypothetical "thermogen" and the simultaneous absorption of energy. The former were excitors of heat production inasmuch as they induce destructive metabolism with oxidation and the liberation of energy. Briefly this view of thermogenesis was suggested (1) by the chemical fact that in the normal thermogenic, as in the normal contractile, metabolism of muscle there is no adequate evidence of increased nitrogenous waste, but only of the absorption of oxygen and the liberation of carbonic acid and water; the nitrogenous molecule of the muscle substance must be continuously upbuilt again as it is continuously being unbuilt, anabolism going hand in hand with catabolism; and (2) by the cardinal physiological doctrine taught us by Dr. Gaskell, that catabolism or disintegration is the symptom of "motor" or "excitor" nervous action, and anabolism or restoration of "inhibitory" nervous action. The physiological doctrine was, you will remember, strongly supported by the phenomena presented by the heart muscle and its double nerve-supply through the sympathetic and the vagus; it was rendered probable in the case of the visceral and vascular involuntary muscles, and on analogical and other grounds inferred in the case of the voluntary muscles and the secreting glands.

Another line of analogical reasoning to which you may or may not be inclined to give weight suggested that, as the nervous mechanisms of heat loss—namely, those subserving circulation and respiration—had a twofold character, and were maintained in balance by the joint action of opposing influences, respectively motor and inhibitory, so too the nervous mechanism of heat production was twofold, and in health maintained a "thermogenic tonus," a balance between tendencies towards the liberation of thermal energy on the one hand and its repression or absorption on the other.

I have to confess that we know little or nothing as yet of the anatomical course of the thermal nerves of the muscles. The motor trunks would appear to contain the thermogenic fibres—if, indeed, they are not identical with the motor fibres. But as to the course of the anabolic fibres we can only conjecture, and the analogies which we have to guide us are too obscure for me to dwell on here. This ignorance would be more depressing if we held to the notion that anatomy had fulfilled its task and explored exhaustively the whole field of the peripheral nervous system. But when I remember that it is only since the other day that the physiological, anatomical, and morphological relations of the so-called sympathetic system to the spinal nerves have been at all clearly understood, I do not despair of further great discoveries. In my own opinion the work of anatomy, guided by the light of physiological research, is in this domain scarcely even begun. When it is complete I have little doubt that the relations, anatomical and morphological, of the anabolic nerves to the central system will appear as definite as those of the motor nerves.

I proceed to consider some of the attempts that have been made to trace the thermal nerves into and through the central nervous system. I do not for a moment profess to

Digitized by Google

give a complete summary of all that has been done, even in recent times, to investigate the relations of the cerebro-spinal system to thermogenesis. A very large number of these researches are to my mind vitiated, in that they are merely thermometrical. Without calorimetry, or—what in a sense we may regard as equivalent—the measurement of the oxidative or other destructive metabolism accompanying experimental lesions of the nervous centres, we can infer little that is certain as to the mechanism of heat production. The concurrent effects of the processes of heat loss are not easily to be eliminated or allowed for, and the results thus complicated are at best ambiguous.

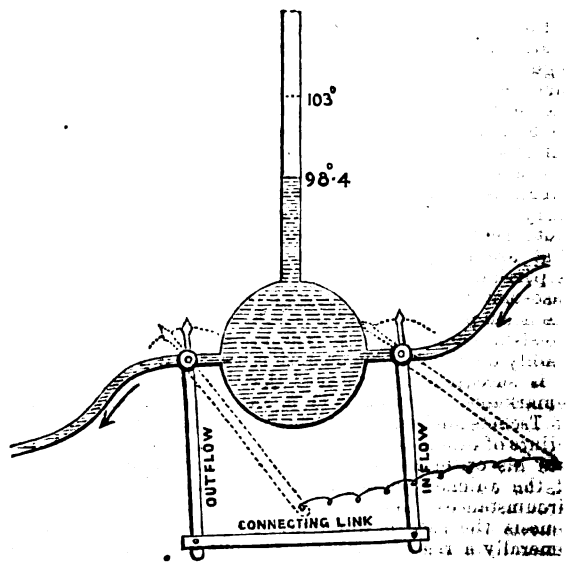
To take a familiar example: it has been known from the time of Sir Benjamin Brodie that section of the spinal cord is in some cases followed by a surprising rise of the body temperature. In other instances the temperature falls; and some observers have found that according as the animal is exposed to a warmer or cooler medium, according as it is wrapped up or naked, its temperature will ultimately rise high or sink low. Wood has shown how these inconsistencies may be reconciled by measuring the actual heat produced by an animal before and after section. As the result of many rigorous experiments, he is able to state as demonstrated, that "section of the spinal cord above the origin of the splanchnic nerves is usually followed by an immediate very decided increase in the amount of heat dissipated from the body, and also by a decided lessening of the amount of heat produced." The vaso-motor tracts being divided in these experiments, it is certain that vaso-motor paralysis has a great deal to do with the increased loss of heat, while the paralysed muscles, being cut off from their regulating nerve-supply, are apt to have their thermogenesis increased or diminished by the high or low temperature of the surrounding medium, much as when they are poisoned with curare. The temperature of the body is thus the resultant of a number of diverse thermal tendencies; and as one or the other is in the ascendant the temperature rises or falls. Successively higher and higher sections of the cord at length carry us to a level above the highest or dominating vaso-motor centre in the medulla, and not till then do we get results that are fairly uniform and intelligible. If the medulla is partially divided close to its junction with the pons, the vaso-motor mechanism appears to remain intact; at any rate, the usual physiological test of its integrity—marked rise of blood-pressure when a sensory nerve is stimulated—is readily obtained. The operation itself is not easy, but when it is successfully performed the thermal consequences are remarkable. I attach little importance to the alleged results of Tschetschichin, now twenty years old, or to the alleged failure of others since to confirm them. Both the discoverer and his critics seem to have tested merely the temperature of the animals operated on; and this varies according to circumstances. But when we come to measure the thermogenesis the case is different. In the dog at least there is generally a rise of temperature; but whether this happens or not, the rate of heat production is invariably augmented. Heat loss is also increased, but it seldom keeps pace with the heat production. Moreover, the increased heat production is not simply transient, it goes on for a long time, and in some instances is greater twenty-four hours after operation than it is at first. Again, when the same region—namely, the part of the medulla which immediately adjoins the pons—is mechanically irritated by a puncture, in several instances a marked temporary fall in the rate of heat production has been observed (Wood), though in others electrical stimulation of the part is said to have been followed by a prompt rise of temperature at least.

These experiments certainly suggest the hypothesis that the region in question is traversed by some of the anabolic or inhibitory fibres. Severance of them is followed by a disturbance of the balance I have called thermogenic tonus; the inhibitory influence being cut off, the excitor influence has full sway. Irritation of the same tract is followed by a temporary diminution of thermogenesis, just as irritation of the vagus tract is followed by a temporary diminution of the contractile activity of the heart. I have scrutinised the tabulated results of the published experiments to see whether there were any traces of an increased vigour of the thermogenic function following the temporary diminution, such as might be expected to result from the stimulation of an anabolic nerve, and such as we find to follow the vagus inhibition of the heart (see Lecture II.). The figures are unfortunately insufficient for the purpose, with one exception, given in Wood's series. In this case puncture of the pons-medulla at first lessened the heat production by no less than two-thirds. But in twenty-four hours, in spite of the exhaustion of the animal, in spite too of its prolonged abstinence from food, the rate of heat production increased again to within one-fifth of the normal rate. This at least suggests considerable vigour in the thermogenic function, and it may be an instance of improvement following inhibition.

Professor Wood has gone further in his attempts to trace upwards the inhibitory tract. He has sought, following Eulenburg and Landois, to determine the influence of certain cortical and subcortical lesions upon thermogenesis. His methods for producing the experimental lesions are no doubt less refined and precise than those to which the classical researches of Dr. Ferrier have accustomed us. But his results, extending to some twenty laborious experiments, are so uniform and so striking that, if we accept his statement of them at all, it is difficult to resist the conclusion that severe injury of certain regions in the cortex or beneath it is, in the dog at least, followed not merely by rise of temperature—that is of secondary importance—but by increased production of heat. The cortical area is just posterior to the crucial sulcus, and corresponds in Hitzig's and Ferrier's scheme to the motor region for the muscular masses of the limbs. The experiments in which stimulation rather than destructive injury of this region was attempted are neither numerous nor altogether satisfactory, but so far as they go they agree with the older experiments of Eulenburg and Landois, in which local electrical stimulation of one of the areas was followed by a slight temporary *cooling* of the opposite extremities. Dr. Ferrier, in the last edition of his great work,[1] regards this as due to contraction of the bloodvessels, and the long enduring and considerable increase of heat production which follows destruction of the areas as due to dilatation of the vessels. Changes in the distribution of temperature may, and do, result from changes in the vascularity of the tissues; but I know of nothing that justifies us in straightway assuming that such changes affect thermogenesis. The *mere* flushing of a muscle with blood need not increase the metabolism of the muscle substance, unless the latter is simultaneously stimulated to functional activity, unless it is moved *ab extra* to take advantage of the opportunities for assimilation which are offered to it. Cut off the innervation of a muscle by curare, and you may cause the arterial blood to rush through its vessels without appreciably increasing its oxidative metabolism. For this reason, in addition to those given by Professor Wood, I am unable to correlate the thermogenic phenomena resulting from destruction or stimulation of the cortex with vaso-motor changes: I say nothing for the present of the thermometric phenomena. So far, then, it would appear that there is experimental evidence that the tract containing the nerve fibres inhibitory of the thermogenic function of the muscles runs through the medulla into the pons; there is, moreover, experimental evidence that, in the dog at least, a cortical or subcortical region coinciding in part with the motor region is concerned with thermogenesis, and is probably in connexion with the inhibitory tract.

Allow me next to call your attention to an interesting series of experiments by Messrs. Aronsohn and Sachs of Berlin. They are thermometric, not calorimetric, and therefore at first sight bear on temperature rather than thermogenesis; but as simultaneous measurements were made of the oxygen consumed and the carbonic acid discharged, we are able to draw from them certain conclusions of interest as regards febrile heat. Some of the striking phenomena in question were shown to a number of the visitors to the Berlin Medical Congress in 1885.

When a puncture with a fine needle is made through the brain of a rabbit in such wise as to pass vertically through the medial side of the corpus striatum near the *nodus cursorius* of Nothnagel, the temperature in the muscles and in the rectum promptly rises from 1½° to 2½° C., or say 2½° to 4½ F., and remains high for many hours, returning ultimately to the normal again. The animal appears to be but little affected by the operation, and eats and moves about gaily. It need not be tied up or confined in any way, and the temperature of the room may be ordinary. But the result seems invariably to follow, and it can be reproduced again and again in the same animal. It is not due to irritation or injury of the cortex or of the white



[1] Functions of the Brain, ed. 1886, pp. 87, 253.

Digitized by Google

matter immediately underlying it, for superficial or shallow punctures are without effect. The sensitive region is of no great extent, and can be defined with considerable precision. The question that always rises in experiments of the kind rises here also: Is the result due to stimulation or to destruction of the nervous elements that are punctured? Our experimenters have apparently answered this question in a satisfactory way. By a highly ingenious method they succeeded in passing a weak electric current through the sensitive region, and that without exciting any of the neighbouring parts. The result was striking. The temperature in the muscles rose with every passage of the current, and could at will be kept at a febrile height for many hours together. The rise of temperature appeared thus to be unmistakably due to stimulation, and not to injury. And here remark that the febrile condition could hardly be due to any contraction of the cutaneous vessels, to any *retention* of heat, for it was observed that the temperatures of the skin, the muscles, and the rectum rose and fell together. Moreover, when means were provided for estimating the oxygen consumed and the carbonic acid given off, they were found to be increased during the artificial fever to about the same extent as in ordinary fever of like intensity, and the nitrogen excreted in the twenty-four hours after the puncture was something like 25 per cent. greater than in the twenty-four hours before the puncture. From all these facts the conclusion is hardly to be resisted—that by the stimulation of a particular region to the inner side of the corpus striatum the thermogenic function of the muscles is abnormally increased, and therewith their catabolic or oxidative metabolism; and this, without encroaching on the motor tract, without exciting the motor function, and without any action that can fairly be called vaso-motor, coming into play. I am not going to say that the circumscribed region of the brain so carefully explored by Messrs. Aronsohn and Sachs is a thermogenic "centre," for I know that by some pathologists the word is banned. But I do say that, if the evidence is worth anything, it proves that the region is connected intimately with the thermogenic tract; that the catabolic fibres which proceed to the muscles and in them excite the thermogenic function, are here capable of being reached and stimulated apart from the motor nerves. It is this fact which makes one hesitate at once to say that the thermogenic fibres to the muscles are identical with the motor fibres. It is not easy to see how they can dichotomise again at their central terminations, the motor running through the internal capsule, the thermogenic quite to the inner side of the corpus striatum.

There is another aspect in which we may view these experiments. During the period in which the sensitive spot is being at intervals electrically stimulated, the animal's temperature is markedly raised, its rate of heat production is apparently increased, it is consuming more oxygen and giving off more carbonic acid than is normal; by all the signs of disordered body heat, by all the symptoms which imply pyrexia, the animal is in a state of fever. When the stimulation ceases the fever subsides. In other words, by exciting to excessive action a particular spot within the brain, we can bring about a fever of moderate intensity indistinguishable while it lasts from any other produced in more familiar ways. We have generated a fever by a direct action on the central nervous system.

Before I proceed to suggest to you my own belief that all fever is due to an action on the central nervous system, I must anticipate a possible misunderstanding. I have more than once remarked, in passing, on the distinction between high temperature and increased heat-production. It is due to you, and necessary to my remaining arguments, that I should make clear wherein the distinction is of importance. In my first lecture I spoke of disorder of the body heat as the essential condition of fever, whose frequent and most manifest symptom is high temperature. But I now go further, and say that high temperature is not necessarily fever, and that fever is not necessarily accompanied by high temperature. We may have a *febris sine febre*, a morbid thermogenesis without high temperature, the increased heat-production being compensated or more than compensated by increased heat loss. And we may have a rise of temperature even with diminished thermogenesis, if the heat loss is so diminished as no longer to balance even the diminished production. The former would be fever, though the patient were cool; the latter would not be fever, even though the patient were hot. It is the excessive thermogenesis, with the excessive catabolism of nitrogenous tissue which that involves, that constitute fever. Without this condition the mere temperature may run for a time to a "paradoxical" height, to a point at which we might expect the albumens of the body to coagulate; and yet the patient may recover, and promptly too, for there has been no excessive combustion, no consuming of the tissues. Consider on how slight a dislocation of the normal relation of gain to loss a marked rise of temperature may depend. An adult man in ordinary health breeds enough heat in half an hour to raise his own temperature one degree Centigrade. In half an hour he discharges an equal amount of heat into the air, and so his temperature is *not* raised. But suppose for a moment that all automatic connexion between the two processes were broken for the space of an hour, that the two could work independently of each other and of the temperature. Suppose further that the heat loss were somehow checked entirely for the hour and then restored to its normal rate. The heat-production need not alter a jot, but it would all go to raise the temperature: at the end of the hour the temperature would be higher by 2° C. or 3·6° F. Open now the channels of heat loss: they will carry off at the old rate, and the temperature will rise no further; but it will now remain permanently at 102° F. This rise of temperature has been produced, not by any increase of thermogenesis, not by any ultimate diminution of heat loss, but simply by a little "lagging" of the latter process behind the

former. The two have become balanced again, but the temperature does not fall unless the loss goes beyond the balancing point. And what is thus true of lagging in time is obviously true of lagging in degree. If the heat loss is not in abeyance, but merely a little less than the heat gain, the temperature will rise until it reaches a point at which the two are balanced again, and will remain there if the balance once obtained is maintained. In other words, the difference between the rate of heat production and the rate of heat loss at any moment is measured not by the temperature, but by the *gradient* of the temperature. The temperature itself, when it reaches its height, indicates the time it has taken for the one process to gain upon and at length overtake the other, but tells nothing as to the absolute activity of either. High temperature may thus be an indication of mere sluggishness or lagging, and is not *per se* an indication of increased heat or of increased combustion.

I have imagined that a working model might be arranged to illustrate this plain but constantly overlooked fact. (See woodcut.) Suppose a tall vessel containing water: the level of the water shall represent temperature. Let two pipes be connected with the vessel, the one bringing water to it, the other carrying it off. Let each be provided with a stopcock, and let the two stopcocks be connected by a rigid link which ensures that they always turn together and by the same amount. If, to start with, the inflow and outflow are equal, then, however I move the linked stopcocks, the height of the water will remain the same. Loss balances gain in every

Digitized by Google

position. Now remove the link and connect the stopcocks by a weak indiarubber band or a spiral spring. If I now move the inflow stopcock so as to increase the flow, the outflow one will not at once follow, and, the balance being broken, the level of the water will rise. Presently, as the elasticity of the spring comes into play, the outflow will become equal to the inflow, and the rise will cease; but the new high level will be maintained. Every movement of either stopcock will affect the level, which will fluctuate accordingly, but its height at any moment will not be an index of the amount of inflow at that moment. The inflow may be slight while the level is high. Of course inflow represents heat production, outflow heat loss, and the rigid link which first connected the two stopcocks the healthy thermotaxic mechanism. When this latter is weakened, or relaxed, or broken, the steadiness of the normal level is impossible. The fact that in fever, after the thermotaxic mechanism is disorganised, the temperature so frequently rises, shows that the next step in the process is usually excessive thermogenesis; and the fact that the temperature does not rise indefinitely shows that the mechanism of heat loss is less disordered or only transiently disordered, for though at first it lags behind the heat production, it ultimately overtakes it or overpasses it.

There is thus a certain order of progression observed in the disturbance of the thermal relations of the body. First and most easily disturbed is the thermotaxic nervous mechanism. If that is all that is disturbed, we shall have strange risings and fallings of temperature as the independent variations of production and loss are concurrent or the reverse, but there need be no fever. The balanced rhythm of anabolism and catabolism in the muscles is not disturbed; there is no excessive oxidation and no excessive inhibition. And the balanced rhythm of the respiration and the cutaneous circulation is also maintained, and with it the process of heat loss, but the latter need never be very excessive or very deficient. All that happens is that the two rhythms do not harmonise, and the fluctuations of the temperature correspond in a measure to the "beats" which are heard when two tones are sounded together that are nearly but not quite in concord. Cases of this thermal ataxia are not wanting; one such was under my charge for a time when acting for Dr. Paget at Addenbrooke's Hospital. He has described it in THE LANCET of July 4th, 1885. The patient was paraplegic, with at times a remarkably unstable temperature. For instance, on one day, when there was a trifling irregularity of the bowels, it ran up to 109·2° F., the pulse being at 80 and the respiration at 22; in three-quarters of an hour it was down to 97·8°. On another day it reached 110·4°, and in half an hour fell to 98·8° again. But there was no evidence of increased thermogenesis, no wasting, no failure of nutrition. Many similar "paradoxical" fluctuations of temperature, without fever, have been described.

The next degree of disturbance is that in which there is not only thermal ataxia, but disorder of the parts of the nervous system subserving heat production: there is under-action of the anabolic nerves with diminished construction and diminished absorption of energy; there is over-action of the catabolic nerves with increased oxidation and thermogenesis. Both factors of the normal thermogenic tonus are probably disordered together, but as I believe there is good reason for regarding the anabolic mechanism as "higher" than the catabolic, so there is reason for the view that it is in many cases the first and the most disordered. Weakening or abolition of the inhibitory influences with defective upbuilding of the "thermogenic stuff" in the muscles probably precedes excessive catabolic action, and to this may be due the pre-febrile discharge of urea which is occasionally observed. But soon the other factor of the thermogenic mechanism is disordered also, and there is excessive heat production. The net result is apparent wasting or "combustion," and generally high temperature. The thermotaxic mechanism is in abeyance; the immediate adjustment of heat loss to heat production is consequently hindered, the thermogenic mechanism gets a start, as it were, before the heat-discharging mechanism is called into play. Once the temperature is somewhat raised, the latter mechanism, if it is not itself disordered, is capable of increased activity and presently overtakes the work thrown upon it. But the "lagging" of the one process behind the other finds expression in the heightened temperature. This is ordinary pyrexia, and the nervous disorder does not in general go further. But there is another stage—namely, when the mechanism of heat loss is also profoundly disordered, so that the rise of temperature from the antecedent excessive thermogenesis does not stimulate it (or does not stimulate it enough) to make it overtake the latter until the temperature reaches an excessive or even a fatal height. This is hyperpyrexia.

To resume. The thermal nervous system has three parts; let us call them briefly the thermotaxic or adjusting, the thermogenic or producing, and the thermolytic or discharging mechanism. Disorder of the first implies irregularity of temperature only; disorder of the first and second implies, in general, heightened temperature and increased body heat—that is, ordinary fever; disorder of the first, second, and third implies, in general, hyperpyrexia, dangerous increase of heat, and steadily *rising* temperature. In the ascending scale of evolution we seem to rise from the thermolytic to the thermogenic and then to the thermotaxic nervous system. Cold-blooded animals possess the mechanism that in mammals becomes thermolytic—a nervous mechanism that controls the vessels and the breathing. The thermogenic system in them is ill-developed, and probably not well differentiated from the system of motor and inhibitory nerves that subserves locomotion. The frog in a normal condition hardly needs to generate heat in his muscles, but when the motor trunks are artificially stimulated heat *can* be produced in them. But his oxidative thermogenic metabolism is at best feeble, and we cannot easily throw him into an enduring fever. In young mammals the thermogenic system is developed before the thermotaxic. The instability of an infant's temperature is its chief characteristic. A little sends it into a high fever; a little restores it again. As the child grows, the range of its power of regulation increases, its temperature grows stable, and the thermotaxic mechanism is evolved.

Time fails me to say more as to the successive evolution of the three mechanisms from what we may call the historical point of view. The consideration of their organisation leads us, however, to a like result. In Dr. Hughlings Jackson's words, "Evolution is a passage from the most to the least organised—that is to say, from the lowest well-organised centres up to the highest least-organised centres; putting this otherwise, the progress is from centres comparatively well organised at birth up to those, the highest centres, which are continually organising through life." The order of organisation is, like that of evolution, — thermolytic, thermogenic, thermotaxic. The localisation of the thermolytic centres is admitted even by the opponents of localisation; they do not object to speak of the vaso-motor, respiratory, and sweat centres. The best organised and the most automatic centres are the best recognised, and the lowest. The cerebral thermogenic mechanism I have hardly ventured to speak of as consisting of "centres." Yet some observers claim to be able to point to the inhibitory centre, and others, as competent, to the excitor centre. I have laid before you specimens of both claims; that they are not universally admitted is to me evidence that the organisation of these thermogenic centres is less complete and therefore less localised; that they are, in a sense, in process of evolution; that they are higher than the thermolytic. As to the thermotaxic mechanism, no one, so far as I am aware, has been able to say it is at this spot or at that. Least organised, least automatic, least and last developed, its localisation is necessarily the most imperfect. But its existence I take to be as necessary as that of the "highest motor centres," which control and connect and represent the "middle motor centres" localised in the cortex. It coördinates because it represents the thermogenic and the thermolytic centres.

You will see from what I have said that, regarding the thermal mechanisms as a functional and evolutional hierarchy, I regard fever as a "dissolution," a progressive negative process, a relaxation of control from above downwards, in the same sense (and with the same reserves) that the term is used by Dr. Hughlings Jackson in his Croonian Lectures of 1884. The ideas set forth in that most suggestive course with reference to the evolution or dissolution of the motor functions I venture in all deference to apply to the correlative thermogenic function. If I may so express myself, the pains that have been taken to adjust our thermal relations to our environment, the nicety of the balance in widely varying circumstances, the impairment of all the higher functions which ensues when the balance is but a little disturbed in either direction move me to regard

Digitized by Google

thermogenesis as no mere by-end of our nature, no mere casual but unavoidable concomitant of chemical processes performed for another primary purpose. I would put it in the vital scale a little "higher" than circulation and respiration, and a little "lower" than voluntary muscular action. The motor function of the muscles is related to the highest centres; their thermogenic function connects them with the lower or animal centres; and the innumerable variety of causes which disturb or "dissolve" the controlling nervous mechanism, the readiness of "fever" to result from injurious influences of so many kinds, is the expression of the fact that the habit of stable temperature is, so to speak, recently acquired. As a last test of the "dissolution" hypothesis, consider what happens in recovery from a typical febrile attack. First, the thermolytic mechanism is waked to adequacy, there is a critical sweat or a relaxation of the vessels of the skin, and a gush of heat from the surface brings down the temperature with a run. But the thermogenic centres have not yet recovered, and the temperature will swing backwards and forwards for some days, and an epicritical excretion of urea takes place. Thermogenesis becomes less and less excessive, and is vigilantly counterbalanced by thermolysis; but thermotaxis is yet feeble. The patient's temperature is down, but it is still far from stable. As convalescence proceeds the stability increases, and at length thermotaxis, the first to be disturbed and overthrown, is the last to be restored.

The task which I proposed to myself is fulfilled; it was to set before you, if not an idea, at least the germ of an idea concerning the nature of fever. At every turn I have been indebted to the work of others; theirs are the pearls of observation and experiment which I have so inadequately displayed to you: only this tenuous filament of a theory on which I have strung them together is mine. But as some coherent theory is better than none,[2] if only as an aid to the ordering of our facts, and as I have found this manner of looking at fever useful to myself, not only as a pathologist but as a physician, I have ventured thus imperfectly to propound it. I have said nothing of the many clinical facts which might be adduced in support of the nervous origin of fever; Dr. Hale White has done so once for all in an excellent paper in the Guy's Hospital Reports (1884). I have said nothing of the therapeutics of fever, for indeed there is probably no Fellow of the College here present who could not teach me many lessons as to its treatment. And if, lastly, I have said nothing about etiology, that has at least this advantage, that you have been spared even a single allusion to bacteria.

CASE OF

CEREBRAL ABSCESS DUE TO OTITIS MEDIA,

UNDER THE CARE OF DR. BARR, AND OPERATED ON.

REPORTED BY

WILLIAM MACEWEN,

SURGEON AND LECTURER ON SURGERY, ROYAL INFIRMARY, GLASGOW.

SUMMARY.—*Abscess in temporo-sphenoidal lobe, due to septic otitis media; doubtful condition of lateral sinus; lungs involved; symptoms; operation; complete recovery.*

W. H——, a boy, aged nine years, was admitted into the Hospital for Diseases of the Ear under the care of Dr. Barr, on Jan. 13th, 1887, suffering from septic purulent otitis media and abscess of the brain, for the latter of which I was ultimately consulted, and afterwards operated upon him.

History.—The history prior to his admission into the hospital, as given by his mother in answer to questions, is as follows:—A month prior to the operation about to be described he complained one day of pain in the region of the right ear, which made him fret and prevented him from sleeping at night. On the following morning his skin was hot and dry, and he vomited, after which he became drowsy, being frequently awakened, however, by sudden startings and "crying fits" due to acute pain. The pain over the region of the ear, the drowsiness, the feverishness, and the occasional vomiting continued to characterise the first seven days of his illness. On the eighth day he had a rigor which lasted a quarter of an hour, in which he shook all over, and his teeth chattered. Between this time and his admission into the institution, he had in all six rigors, at intervals of about two days.

On the nineteenth day of his disease he was admitted into the Hospital for Diseases of the Ear. His condition was then as follows: He was a greatly emaciated child, having a pale, shrunken face, with livid lips, his upper one being covered by herpetic eruptions. He had a short catching cough. His axillary temperature was 100·8°; pulse 108. He was very drowsy, and complained of pain over the right ear, from which there was an offensive discharge. Dr. Barr found a perforation to exist in the upper part of the tympanic membrane, from which some purulent secretion was escaping, although the quantity was not great. There was defective hearing on that side, but the boy's mental condition prevented an exact estimate of the degree of deafness. For two days after admission (twentieth and twenty-first days of illness) his complaints of pain were not obtrusive, but the drowsiness continued. On the next day the pain had become aggravated, and he had a slight rigor. There was no evidence of an acute inflammatory process, or of retention of pus in the ear, to account for the pain, and there was neither redness nor swelling over the mastoid process. The temperature at this time was 99·6°; pulse 92. Dr. Barr perforated the mastoid process, and opened into the mastoid cells by chiselling behind the external auditory canal, and succeeded in passing a stream of antiseptic fluid through the antrum and tympanic cavity, out by the external meatus, and also in the reverse direction. A small quantity of purulent and caseous débris was washed out. A drainage-tube was introduced into the orifice in the bone through which an antiseptic solution was injected twice daily from the opening behind to the external meatus, and *vice versâ*. For two days subsequently no change was observed in his condition, but a slight rigor occurred on the second day after the perforation (twenty-fifth of the disease), while the pain in the head and the drowsiness became worse. On the twenty-ninth day of his illness a copious discharge of most offensive odour escaped from the ear. His tongue was red and smooth, and he refused to take food or drink. Pulse intermittent and irregular. A blush of redness frequently suffused the face.

On the thirtieth day of his illness Dr. Barr asked me to see a case in which he suspected cerebral abscess. The boy's state was then as follows: On approaching his bed one perceived a heavy fetid odour, traceable to the discharge from the right ear. One saw an extremely emaciated child, with a pale, greyish face, wrinkled skin, prominent cheek bones, and somewhat sunken eyeballs. He lay upon his right side in bed, his hand beneath his head, looking as if he were asleep with his eyelids half open. His lips were livid, and on the upper one herpetic remains appeared. His tongue was red and dry. Sordes covered the teeth. When an attempt was made to rouse him the right upper eyelid drooped, and there was a shade of passivity of the right side of the face, with a slight dragging of the angle of the mouth toward the left. The conjunctiva of the right eyelid was congested, and the lids were smeared with pus. The pupils were equal, about medium size, and responded sluggishly to the action of light. The veins over the right side of the head were congested, and stood prominently out on his shaven head. Pain on percussion was elicited over the right temporal, while percussion over the head generally was calmly borne. There was no œdema about the mastoid process. The right sterno-mastoid muscle was rigid. There was no hard cord-like feeling along the line of the internal jugular, though the external jugular was prominent. Acute pain was elicited on digital pressure just behind the origin of the sterno-mastoid, in the tissues near the exit of the vein which passes through the posterior condylar foramen. He was in a state of stupor, from which he could only be partially aroused, and not to such an extent as to give an intelligent answer to any question. His pulse was markedly slow, 50 to 60 per minute, and was feeble and intermittent. His limbs were extremely attenuated, and there was an irregular muscular tremor over the body generally, such as one frequently finds in approaching dissolution. He had a frequent cough, with purulent expectoration, which had an offensive odour, and there were moist râles over both sides of the chest. His bowels were and had been obstinately constipated. His urine was

[2] "We should follow the method of science, and investigate by the use of hypotheses. This may seem a strange remark to those who erroneously suppose an hypothesis to be a conclusion in which we may rest. It is only used for the methodising of work by observation and experiment."—(Hughlings Jackson: Bowman Lecture, 1885.)

Digitized by Google

free from albumen. It was somewhat difficult to believe that some weeks previously this boy was apparently stout and robust, and was vigorously engaged at playing football. There was a flow of excessively fetid fluid from the external ear, and as this was greater in amount than what would be likely to come from the antrum or middle ear, it was suspected that there might be a connexion between the middle ear and the intra-cranial cavity. There was no difficulty in concluding that this patient suffered from cerebral abscess, originating in septic otitis media. It was almost positive that it was situated in the temporo-sphenoidal lobe, and it probably had a tortuous and minute communication with the middle ear. It was feared that the lung affection was secondary to the septic absorption. The prognosis was almost hopeless, his youth being the one favourable point. Immediate operation was advised, and with Dr. Barr's concurrence it was at once carried out.

Operation.—The middle ear was washed out with an antiseptic solution, and rendered as nearly aseptic as possible. The scalp and parts around the ear were carefully washed with soap and water, then they were cleansed with turpentine, and finally with methylated spirit. An anæsthetic was administered. A half-inch disc of bone was removed from the squamous portion of the temporal, at a point an inch above and half an inch behind the centre of the external auditory meatus. The bone was normal; the dura mater was here slightly congested, and did not impart any brain impulse to the finger, neither was any discernible when the aperture in the skull was filled with fluid. When the membrane was opened and turned aside, the brain tissue immediately bulged into the osseous cavity and rose above its external level. The pia mater covering it was congested, and the brain substance had a yellowish-red appearance. A hollow needle was inserted into the brain in a direction which, if introduced far enough, would strike the eminence in the petrous bone above the middle ear. After it had penetrated the brain tissue for about three-quarters of an inch, there was a sudden escape of foul gas, accompanied by a bubbling sound and the escape of a few bells of fluid. Evidently the upper part of an abscess cavity had been tapped, and this contained fetid gas. The needle was inserted a little further, when pus flowed out. It was of an ordinary yellowish colour, and had a most offensive odour. After two drachms had slowly welled away, the aperture in the brain tissue was enlarged by forceps, and portions of the brain tissue, which had become necrosed, were removed. The latter consisted of shreds, two about the size of a large horse-bean, the others that of barley grains. On their removal more pus welled away. The cavity was then washed out with a saturated solution of boracic acid. After that, however, there was still a slow oozing of pus, along with the extrusion of minute shreds of brain tissue. It was evident that there was a considerable zone of purulent inflammation surrounding the abscess cavity, from which the pus continued to ooze. An aperture was then drilled into the base of the skull, just above the osseous boundary of the external auditory meatus, involving the squamo-petrosal suture. The dura mater was examined here and found intact. It was penetrated, and the abscess cavity was reached. A stream of boracic lotion was passed from this aperture so as to wash out the cavity of the abscess, and it was continued until it passed freely out by the upper opening. The current was then reversed. Even after that, when the drainage-tube was inserted, an oozing of purulent fluid took place into the tube. The ear was again cleansed. Chromicised chicken-bone drainage-tubes were introduced into both apertures. The parts were thickly dusted over with boracic acid powder, and dressed with sublimated wood-wool pads.

When placed in bed the patient was extremely weak, but rallied after the first few hours. A marked improvement was observable during the first week. The pulse became quicker and the temperature a little higher, both good signs. The face became brighter, the eyes clearer, the eyelids free from pus, the ptosis vanished, and the mental condition improved. After the first week, though kept on restricted diet, he improved in flesh, and continued subsequently to do so at a rapid rate. The wounds were dressed about once a week, when the parts were thoroughly syringed with saturated boracic solution, the drainage-tubes being gradually curtailed as the granulation tissue blocked them out. The softened brain tissue at the seat of the upper opening in the skull soon presented a mass of granulations, which increased in size, and rose into the aperture in the bone, uniting with the layer which formed on the exterior of the skull. Soon the two became blended together, and cicatrisation rapidly progressed. The chromicised chicken-bones answered admirably as drains, notwithstanding the action of the tissues, until they were removed, the upper one after fully five weeks. They also presented the advantage over silver ones, of being easily shortened when required.

The child put on flesh rapidly, and at the end of six weeks was quite plump.

Dr. Reid examined the eyes about the end of the fourth week after the operation, and could find no trace of optic neuritis. He was of opinion that optic neuritis could not have been present at the time of the operation, without having left some traces of its presence four weeks after.

On March 17th, Dr. Barr examined the affected ear. There was still slight purulent secretion coming from the granulation tissue in the middle ear. The hearing power was as follows: A watch heard forty inches from the ear in normal hearing was audible at a distance of five inches and a half. By bone conduction hearing was very good. A tuning-fork (C) applied to the middle line of the head was heard louder in the affected ear. Pressed in the mastoid process, the tuning-fork was heard much louder than when held near to, but not touching, the orifice of the ear. The results of these tests with the tuning-fork point to a normal state of the labyrinthine and nerve structures.

PYREXIA AND HYPERPYREXIA.

BY T. J. MACLAGAN, M.D., M.R.C.P.,

PHYSICIAN IN ORDINARY TO THEIR ROYAL HIGHNESSES PRINCE AND PRINCESS CHRISTIAN OF SCHLESWIG HOLSTEIN.

(*Continued from page 566.*)

THE poisons of the specific fevers are minute organisms which are reproduced in the system during the course of the diseases to which they give rise. It is this reproduction of the organism in the system which causes the whole disturbance. Before it takes place there is no fever; during its continuance fever is the prominent condition with which we have to deal; after its cessation the fever rapidly declines. How does such a result flow from such a cause? How does the propagation of this poison in the system raise the body heat? It can be only in one of two ways—by impairing heat inhibition, or by stimulating the processes which result in heat production. In favour of the former view, it is difficult to find anything to say except that it is possible. As rise of body heat may be produced in this way (as, for instance, in injuries of the nervous centres), it is within the range of possibility that the fever poison might act by impairing heat inhibition. A very little consideration, however, will show that, though not much can be said for this view, a great deal may be said against it. According to this view of the matter, the poisons of the specific fevers exercise for the time a more or less paralysing effect on the heat-inhibiting centre—the result of which is, of course, rise of temperature. But if such were the case, this action ought to be more and more pronounced as the poison which gives rise to it increases in amount in the system, and the temperature should go on rising as the disease advances, getting daily higher and higher, and keeping pace in its rise with the increasing prominence of the other symptoms—wasting, prostration, delirium, &c. It ought, too, to remain high so long as the poison exists in the system. That is what ought to be if the rise of temperature were due to a direct toxic action of the poison on the heat-inhibiting centre. But the facts are quite the reverse. Take typhus and typhoid fever as typical instances. We find that in these fevers the temperature reaches its highest point very early in the disease—may be even before its characteristic symptoms are fully developed,—and is no higher after two or three weeks of fever than after five or six days of it, though the poison which causes all the disturbance is being largely reproduced during the whole time. Again, it is a fact that in each of the specific fevers the temperature returns to the normal while there is still in the system a large quantity of the poison of the disease, as is abundantly evidenced by the contagiousness of these [illegible] during

Digitized by Google

the early days of convalescence. Did that poison have a direct paralysing effect on the heat-inhibiting centre, and were the rise of temperature due to such an action, the body heat would rise with the increase of the poison, and fever would continue so long as that poison existed in any quantity in the system, and the temperature would not fall till it had been eliminated. As it is, the temperature does not rise after the first five or six days, and there is good reason to believe that the system contains more of the poison at the commencement of defervescence, when the temperature is rapidly falling, than it does during the first few days of the fever, when it is rapidly rising.

The evidence is all opposed to the view that the increased body heat of the specific fevers is of neurotic origin—due to the direct action of the fever poison on the heat-inhibiting centre. Indeed, nothing worthy of the name of evidence can be adduced in support of such a view, and there remains for us nothing but to reject it. It is quite otherwise with the view which attributes the rise of temperature to increased production of heat. What we have now to do is to consider how such increased production is brought about. It will facilitate our inquiry if we bear in mind, what has already been insisted on, that heat is essentially an excretory product, destined for elimination, and that it is not the only such product which is in excess in fever. Fever does not consist solely in rise of temperature; it is a collection of different and various phenomena, all of which are abnormal, and the coexistence of which in the system constitutes a condition which is conveniently characterised by the term "fever." In considering the pathogenesis of this condition, no one of its essential phenomena should be divorced from the others; they are all linked together by the bonds of a common causation, and must therefore be considered together. The specific poison of the disease is the cause which gives rise to each of the specific fevers; that poison must, therefore, be, directly or indirectly, the cause of the individual phenomena which go to constitute the fever. The question for consideration is not the competence of such a cause to produce such a result, for that is demonstrated by the occurrence of the fever, but its mode of action. How does the propagation of the contagium in the system give rise to the thirst, dry skin, quick pulse, rise of temperature, waste of tissue, and disturbance of the nervous centres characteristic of these maladies?

In investigating the action of ordinary poisonous and medicinal agencies, we have to consider only their action on one or more organs, or on the system generally, and have to deal only with the action of the quantity which has been swallowed. It is otherwise with the poisons of the specific fevers. Here we have to deal with an organism which is reproduced in large quantity in the system, and which in its growth and reproduction consumes the same materials as the tissues themselves. All organisms have a definite action on their environment. This action (in the case of such organisms as those of the specific fevers) essentially consists in the consumption of nitrogen and water. The environment of these organisms is the blood and tissues of the human body. The action of these organisms on the body therefore essentially consists in the consumption of its nitrogen and water. As nitrogen and water are the chief elements requisite to the nutrition and building up of the tissues, and as these tissues are dependent for their continued vitality and functional activity on a due supply of nitrogen and water, it is evident that the growth and reproduction in them of millions of organisms which consume these elements must have a seriously disturbing action on the whole system. It shall be my endeavour to show that all the essential phenomena of the specific fevers are attributable to this action—to the consumption by the poisons of these diseases of nitrogen and water destined for the nutrition of the tissues.

The essential phenomena of fever are:—1. Wasting of the nitrogenous tissues. 2. Increased consumption of water. 3. Increased elimination of urea. 4. Increased rapidity of the circulation. 5. Preternatural heat. What we have to do is to apply this view of the mode of action of contagia to the explanation of each of these phenomena.

All the tissues, nitrogenous and non-nitrogenous, waste during fever. In spite of all that is done to support him, the fever patient rapidly emaciates, and wastes almost [illegible] weeks of fever a strong, robust [illegible] as to be unable to sit up [illegible] in it. He may have administered to him during that time a quantity of milk and beef-tea which, were he in health, would tend to make him fatter and to increase his bulk. But the fever process which is consuming him more than counterbalances our efforts to keep him up. Under it he rapidly wastes. What is this process? and how is such wasting brought about? The one cause to which must be ascribed this, as all the other phenomena of the form of fever with which we are now dealing, is the poison which gives rise to the disease. This poison is an organism which is largely reproduced in the system during the course of the malady to which it gives rise, and which in its growth necessarily consumes a large quantity of nitrogen. The only source whence it can get this is one or other of the nitrogenous elements of the body. There exists in the system no spare store of nitrogenous material, but only what suffices for the wants of the system itself. The nitrogen requisite for the growth and propagation of the contagium must therefore be taken from this source, and must represent a loss to the tissues, which is directly as the extent to which the contagium is reproduced.

This consumption of nitrogen by the contagium is one of the main causes of the wasting of the nitrogenous tissues which takes place in the course of the specific fevers. But nitrogen exists in various forms and combinations, liquid and solid, in the body; and we have to consider at what point or points in its changing course through the system it is most likely to be laid hold of by the contagium. Voit has distinguished between the fixed or organ albumen which enters into the composition of the solid tissues and changes slowly, and the circulating or store albumen which is contained in the blood and fluids of organs, and very readily undergoes change. But a still further distinction must be made. The circulating albumen must consist of two parts—a *constructive* and a *retrogressive*: the former derived from the assimilated ingesta, and destined for the nutrition and building up of the tissues; the latter derived from the retrograde metamorphosis of these tissues, and destined for excretion. The former is converted into solid nitrogenous tissue; the latter is converted into urea in the urea-forming glands, and as such is eliminated by the kidneys. Nitrogen thus exists in the system in four different forms—as constructive store albumen, as solid nitrogenous tissue, as retrogressive store albumen, and as urea. From which of these is the contagium most likely to takes its nitrogen? Two things are likely to determine this point: first, the facility with which the nitrogen is yielded up by each of these compounds; and secondly, the special fitness of each for the purpose for which it is wanted by the contagium. The most stable of the nitrogenous compounds, and that which would least readily yield up its nitrogen, is the fixed or organ albumen; that is, therefore, the source whence the contagium is least likely to obtain its nitrogen. The increased wasting of these tissues would, on the first glance, point them out as its probable source; but such a result would equally follow the appropriation by the contagium of the nitrogen destined for their nutrition and repair.

Next in stability is the urea; next to the organ albumen, it is therefore the least likely source from which the contagium should get its nitrogen. But there are more cogent reasons for rejecting it. First, the consumption of the nitrogen of the urea would not lead to wasting of the nitrogenous tissues—would not, indeed, have any effect on these tissues; for nitrogen does not enter into the combination which results in the formation of urea till it has served all the purposes for which it was taken into the system, and is about to be eliminated. Indeed, it takes the form of urea only for that purpose. Secondly, the consumption by the contagium of the nitrogen of the urea would necessarily lead to greatly diminished excretion of that substance by the kidneys; but during the specific fevers there is increased elimination of urea. These reasons make it certain that the urea is not the source whence the contagium derives its nitrogen.

The only other available source is the store albumen. This consists of two parts—a constructive and a retrogressive. From one or both of these the nitrogen of the contagium must be derived. So far as the readiness with which their nitrogen is yielded up is concerned, the two are pretty much on a par; each is a transition compound, and has for one of its leading characteristics a readiness to undergo change and to part with its nitrogen, the one yielding it up to the albuminous tissues, the other parting with it in the gland cells which form it into urea. Any advantage which does exist is on the side of the constructive store albumen; for

Digitized by Google

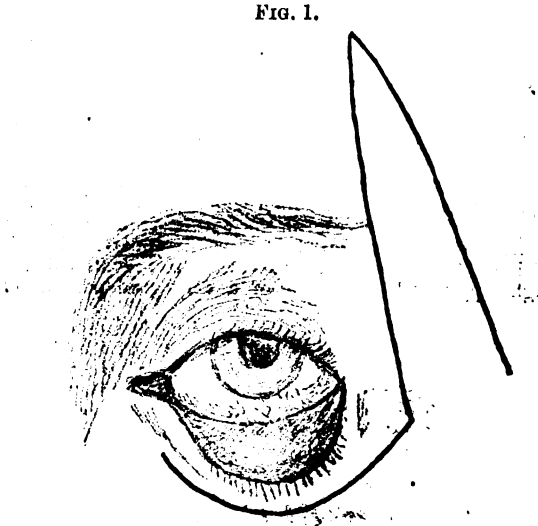
while this is ever undergoing change, and constantly giving up its nitrogen to the albuminous tissues in all parts of the body, the retrogressive yields up its nitrogen only in the urea-forming glands. Now, there is no reason to suppose that the growth of the contagium takes place only in these glands, or that it gets its nitrogen in them only. On the contrary, there is good reason to believe that the contagium appropriates nitrogen all over the body, and in all its tissues.

But there are more cogent reasons for rejecting the claims of the retrogressive store albumen—the same reasons, indeed, which led us to reject those of the urea. The nitrogen does not go to form retrogressive albumen till it has served all the purposes of the tissues; it is no longer required by them—is, indeed, rejected by them,—and assumes this form only that it may be conveyed to the glands, in which it is changed into urea for the purposes of elimination. The retrogressive store albumen is as essentially an excretory compound as is urea. The consumption of its nitrogen by the contagium, therefore, could not cause wasting of the nitrogenous tissues; it would lead only to decreased formation of urea. But all this is exactly the reverse of what takes place: the tissues do waste, and there is increased formation of urea. The retrogressive store albumen is evidently not the source whence the contagium derives its nitrogen. The only remaining source is the constructive store albumen; and a little consideration serves to show that it is also the one whence the contagium would by preference naturally take its nitrogen. The constructive store albumen is the source whence is derived the nitrogen destined for the building up of the nitrogenous tissues; it is only in it that they get nitrogen in the form suitable for their repair. Now, it needs no argument to show that the process by which the protoplasm of the contagium is formed bears a much closer analogy to that by which the albuminous tissues are built up than it does to any other action which goes on in the system. Each is a constructive step, and essentially consists in the appropriation by living protoplasm of the elements requisite for its growth. The particular nitrogenous compound, which serves to build up the protoplasm of the tissues is likely also to be the one which would best serve to build up that of the contagium. Every reason and argument thus lead to the conclusion that the source whence the contagium derives the nitrogen requisite for its growth is the constructive store albumen. The reproduction of the contagium in the system during the course of the specific fevers results in the consumption by it of the nitrogen of the constructive store albumen. This represents a direct loss of nitrogen to the nitrogenous tissues, and such loss is one of the primary causes of that rapid wasting of these tissues which forms one of the characteristic features of an attack of the specific fevers.

But though a primary, it is not the sole agency in producing this loss of bulk. All living and active protoplasm consists mainly of water. Of 100 parts of human flesh, 74 consist of water. A proper supply of water is, therefore, as requisite to the nutrition of the tissues and to the renewal of their protoplasm as is a due supply of nitrogen. But water enters as largely—probably even more largely—into the composition of the protoplasm of the contagium, and is therefore consumed by it during its growth. The growth of the contagium in the tissues means a large consumption of the water as well as of the nitrogen destined for their repair; and this appropriation by the contagium of the water destined for them is probably as potent a factor in the production of that wasting of the tissues which we are now considering as is the consumption by the same agency of the nitrogen of the constructive store albumen. Certain it is that this double loss to the tissues—the loss of water and the loss of nitrogen which must result from the growth of the contagium in the system—affords a reasonable and adequate explanation of the rapid wasting of the tissues which characterises the course of the specific fevers. This consumption of water by the contagium serves also to explain some of the other characteristic and essential ph[illegible]

(To be concluded).

[illegible] supporters of the [illegible] Hospital for Accidents was held on the 16th inst., when satisfactory financial and medical reports were [illegible]



AN OPERATION FOR THE CURE OF ECTROPION.[1]

BY N. DAVIES-COLLEY, M.C. CANT.,
SURGEON AND LECTURER ON ANATOMY, GUY'S HOSPITAL.

I DO not know whether the mode of procedure adopted in the treatment of the following case is new, but, as I can find no mention of it in our text-books, I venture to bring it before the profession, in the hope that it may prove serviceable where the ordinary operations for the relief of this unsightly deformity have failed.

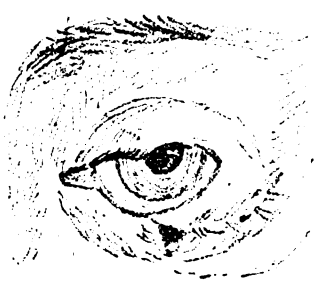
My patient, Michael R——, was a delicate boy of three years of age, who was admitted under my care into Guy's Hospital on Oct. 25th, 1883, with necrosis of the superior maxilla following measles. The left lower eyelid was then much everted, and it became still more so after the removal of sequestra from the front and outer walls of the antrum. In January, 1884, the eyelids were pared and stitched together, and an incision was at the same time made below the lower eyelid to free it. For ten months the child went about with the eye thus closed up, but at the end of that time, when, at the urgent request of the friends, the union between the edges of the lids was divided, immediately the eversion of the lower lid returned. In a short time he was found to have an ulcer of the cornea and considerable conjunctivitis, as the result of the exposure of the eyeball. In January, 1885, I again operated in the same way as before, but this time, in addition to the paring and uniting of the

FIG. 1.

lids, I took a flap more than two inches long, as indicated in Fig. 1, from the temple, and stitched it carefully into the gaping wound produced by the incision necessary to free the lower eyelid. The eversion was so great that I had much difficulty in paring the edge of the lower lid, for it lay at the bottom of a groove which intervened between the prominent granulations of the palpebral conjunctiva and the skin of the cheek. I was disappointed to find, at the end of a few months, that the flap which I had transplanted had not, as in many other cases in which I have operated similarly before, taken the place of the skin of the lower eyelid, but that although it had united perfectly, it had been drawn downwards by the contraction of the soft parts, so as to form the integument of the upper part of the cheek, while the upper eyelid had been elongated, so that its lower border was about on the level of the floor of the orbit. There was a small chink still patent between the inner thirds of the eyelids, through which the boy was able to see a little, but it was evident that if this chink were enlarged by the division of the artificial union between the lids, the eversion of the lower lid would return, and it was

[1] A paper read at a recent meeting of the Medical Society of London.

Digitized by Google



probable that in addition to the deformity the boy would also suffer as before from the exposure of the cornea and conjunctiva. The only way which I could devise for restoring the use of the eye without producing these results was to divide the upper eyelid, and to convert that portion of it which had for some time occupied the position of the lower eyelid into a substitute for it. Accordingly, in May, 1886, sixteen months after the previous operation, I divided, under ether, all the structures of the upper eyelid with a pair of scissors, beginning my incision at the outer end of the chink between the edges of the inner thirds of the lids, and extending it, as indicated in Fig. 2, outwards and slightly upwards for from five-eighths to three-quarters of an inch. To prevent the cut edges uniting again, I then attached

FIG. 2.

the skin to the mucous membrane by fine catgut sutures. From that time until now the boy has been able to use the left eye as well as the right, and there has been no return of the eversion. At first there was some epiphora, but of late the tears only occasionally fall down the cheek. The angle which was formed by the junction of the normal and artificial edges of the new upper eyelid has rounded off, and now hardly attracts notice. He is able to open his eye well, but cannot close it completely, the gap between the lids being about an eighth of an inch wide. There is, however, no conjunctivitis or disease of the cornea from this slight exposure. There are two defects still apparent in his condition. As will be seen by reference to Fig. 3, which is a rough copy that I have made of a very good portrait of

FIG. 3.

him, taken by my late dresser, Mr. Theodore Fisher, some eyelashes emerge from the lower border of what is now his lower eyelid, and there is a small gap, about one-eighth of an inch broad, which must have remained ununited when the eyelids were stitched together two years ago. The great tension of the parts has produced a triangular aperture below the gap, through which a patch of conjunctival granulations can be seen. When the boy has a cold, a few tears escape by the aperture and cause a slight epiphora. I hope on some future occasion to remove these slight defects by a further operation. If I had from the first intended to divide the upper eyelid, it would have been easy to produce a better result by paring away the eyelids so freely as to remove the eyelash bulbs before inserting the stitches. Moreover, I do not think that the preliminary transplantation of a flap is at all necessary to the operation.

Harley-street, W.

RHEUMATIC CEREBRO-SPINAL INFLAMMATION.

BY J. BROWN SIM, M.D., L.R.C.S. EDIN.

THE following case presents many points of interest, as the supervention of grave changes in the cerebro-spinal system are not commonly met with in the course of a rheumatic affection. In this case that disease could never have gone beyond the subacute stage; and beyond the suspicion that the mental faculties had not for some time been quite so sharp as they previously had been, there was no apparent cause why symptoms of so serious and grave a character should have been set up. It possesses many features of resemblance to the case of disseminated myelitis reported in THE LANCET of Nov. 13th of last year, as having been brought before the Royal Medical and Chirurgical Society by Dr. Thomas Barlow, where symptoms of a somewhat similar character had occurred during an attack of measles; and it will serve to point out that the liability to the occurrence of such complications is not confined to the acute specific fevers. Without attempting any explanation of them, I will proceed to give the clinical notes, only drawing attention to the transient character of the first paraplegic attacks, and the subsequent rapid progress of the disease to a fatal termination. I have to express my obligation to Dr. Ransom for his kindness in supplying me with the early notes of the case.

H. S. M——, aged seventeen, occupied as a clerk in a counting-house, first consulted Dr. Ransom of Nottingham on October 30th, 1886, complaining of his left knee-joint being enlarged, and of a swelling on the dorsum of the left hand. On inquiry it was found that the patient's father had had several attacks of rheumatic fever, and frequently the same malady in a subacute form. In other respects the family history was a good one. The patient had about a year before an illness accompanied with pain and swelling of the left knee-joint, which continued for some weeks, but did not lay him up in bed, and from which he completely recovered. For a month previous to his visit to Dr. Ransom the patient had a swelling on the dorsum of his left hand. This had become much reduced in size, but at the time of his visit it was readily felt as a firm substance about the size of half a nutmeg, and apparently deeply placed near the bone. It had been painful, but was not then so. A week previously the left knee-joint again swelled, and was slightly painful and tender. Dr. Ransom detected fluid in this joint. There was also some pain in the back and head. But he did not appear to be feverish, or to suffer much general malaise. Treatment consisted of salicine and iodide of potassium. On Nov. 8th the patient again visited Dr. Ransom, who noted that the symptoms were a trifle better all round. On Nov. 13th the father called on Dr. Ransom and reported that on the afternoon of the 11th his son had suddenly lost the power of moving his legs, and had remained in this state for about a quarter of an hour; that he then recovered, and walked upstairs. That again, about two hours previous to his call on Dr. Ransom, a similar temporary loss of power had come on and passed away. The same afternoon the patient was seen at his own home by Dr. Ransom and myself. He was in bed, and was noted to be thin, pale, and overgrown for his age. It was found that he had completely recovered the use of his legs, and that sensation was normal, as evidenced by his being able readily to localise a pinch or a light touch. The swellings on the hand and knee had almost completely disappeared. On asking the patient to describe the seizure on the 11th, he had at first no recollection of it. On being reminded by his mother, he was then able to recall and give a fairly connected account of it. He described the attack as coming on gradually, beginning with a feeling of numbness in his legs, and passing on to entire inability to move them. He thought it would be quite fifteen minutes in reaching this stage. There was also partial but very slight loss of power in both arms. Since this seizure he was noticed to have some difficulty in passing urine, and to fail in obtaining much relief after doing so. The second attack of paralysis was described as similar to the first, but only affecting the legs, and did not last long. He had not much pain, but complained of some over the region of the stomach. Examination of the spine failed to show any tenderness. The heart

Digitized by Google

and lungs were both normal. The bladder contained a good deal of urine. The mental faculties were clouded, the patient often requiring to be helped out with his facts by his friends. He was stated to have been a bright, lively, intelligent boy, but his father thought him to have been less so for some months past.

Nov. 14th.—10 A.M.: Patient's mind appears to be more hazy this morning. He states that he has had a good night, and has no pain except in his abdomen, which he refers now to the hypogastric and now to the left hypochondriac regions. His memory is worse, as shown by his not remembering that two doctors had been to see him the previous evening. His friends state that he appeared to suffer acutely for four hours during the night, but this he had no recollection of himself. After this attack of pain he appeared to become hot and feverish. He forgets what month it is, and though he made inquiry as to what the thermometer was for when it was put into his axilla, yet he had no recollection of having seen it when it was taken out again. He had also an illusion that there was a clock on the wall. Patient had passed thirty-one ounces of urine during the night, but as his bladder still seemed distended a catheter was passed and thirty-one ounces withdrawn. On examination afterwards the urine was found quite free from albumen. Temperature 100·2°; pulse 114. At 4 P.M. I was summoned to see him, as he had become very violent. He was struggling so much that it was with difficulty he could be kept in bed, and he answered questions very incoherently. Temperature 100·2°.

15th.—10 A.M.: Patient had slept one hour and three-quarters after a sedative prescribed at the last visit, but since then he has been very restless, biting his upper lip, which was cut and much swollen in consequence. He has been passing urine in bed. Temperature 99·8°; pulse 124. Catheter passed and thirty-four ounces of urine withdrawn. —7.30 P.M.: Patient has passed a quiet day, taking liquid nourishment moderately well, but remaining unconscious. He has not been noticed to move his legs to-day. Tickling or pinching them makes no impression. He moves his arms freely, but with this exception he remains in the position he is placed in till he is moved into a fresh one. There has been no urine passed during the day. Twenty-three ounces withdrawn by the catheter. Temperature 98·4°; pulse 126.

16th.—10 A.M.: Patient has passed a quiet night, but was never conscious. He has taken a moderate quantity of milk and beef-tea. Coma this morning is not so profound, as he replies on being asked a question in a loud sharp tone, but could not recognise his friends. No urine passed during the night; thirty-one ounces withdrawn by the catheter. Temperature 102°; pulse 108.—7.30 P.M.: Patient has been comatose all day, only occasionally replying to a question; but has taken more nourishment. He has not been observed to move his legs at all to-day, though it has been specially watched for. He has been perspiring freely, and has been frequently belching. The urine is still retained; twenty-four ounces withdrawn by the catheter. Temperature 103°; pulse rapid, but difficult to count, as he is constantly moving his arm about.

From this time the coma rapidly became more profound, death taking place about 11 A.M. on the 17th, nearly six days from the time he had his first attack of paraplegia. No post-mortem was obtained.

Nottingham.

HULL ROYAL INFIRMARY.—The annual meeting of the governors of this institution was held on the 16th inst., when it was reported that, owing to the transition state which at present existed, it was difficult to frame any report as to the work that had gone on during the past year, or to compare the accounts with those of other institutions. The alterations of and additions to the building were reported to be nearly completed. Dr. Macmillan announced his intention of presenting to the infirmary, as a jubilee offering, a hospital ambulance carriage for the better conveyance of patients to the institution.

THE LUNACY BILL.—At the meeting of the Exeter Town Council on the 23rd inst. it was decided to communicate with the Lord Chancellor, with a view of securing the introduction into the Lunacy Bill now before Parliament of a clause authorising the repayment of money borrowed for building the asylum, to be spread over sixty instead of only thirty years. The Council has just spent £90,000 on a new asylum, and on the present terms of repayment the sum required entails a very heavy addition to the rates

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

AN OVERDOSE OF ESERINE.

BY ANDREW DUNLOP, M.D.,
CONSULTING PHYSICIAN TO THE JERSEY GENERAL DISPENSARY AND INFIRMARY.

A LADY of about sixty years of age, who had slowly advancing cataract in the left eye, and incipient disease of the same kind in the right, began, early last October, to suffer from irritation of the conjunctivæ. The eyes were suffused and the conjunctivæ often somewhat injected, and the discomfort was increased by fatigue, exposure to cold, or strong artificial light. The patient consulted an oculist in London in November, and a variety of constitutional and local remedies were employed without any very satisfactory result. On the 19th of January my friend Mr. Hind saw her with me, and recommended the use of eserine, with the view of lessening the amount of light passing into the eye. Accordingly a solution of the strength of one grain to the ounce was prescribed, and a drop was ordered to be placed in the eyes twice a day. At about 4.30 the same afternoon the first application was made, and a small drop of the solution placed in each eye. A good deal of smarting and lacrymation followed, and as this passed off, in about a quarter of an hour severe clonic spasm of the eyelids set in, the upper eyelid, as the patient described, falling down on the lower every few seconds. About a quarter of an hour later a feeling of spasmodic stiffness in the lips, especially the upper, set in, and soon there was the same sensation under the jaw on the left side. Within an hour there was a feeling of tremor or spasm, but without any actual muscular movements in the arms and thighs, and at the same time there was a sensation of pressure on the eyeballs and of weight and pressure within the head. The patient also began to suffer from some mental confusion, and her memory was impaired. By 11 P.M. the movements of the eyelids had diminished considerably, but the other symptoms had altered very little. She slept uneasily waking at frequent intervals during the first part of the night, and when she awoke was conscious of the same sensation, though in diminishing degree. In the morning the muscular sensations had disappeared, but she felt weak and shaken. I saw her a little before noon on the 20th, when I found the pupils contracted to a fine point, and the conjunctivæ a good deal injected. All the spasmodic muscular feeling had disappeared, but she complained of the pressure on the head and on the eyes. She said there was some mental confusion and a general feeling of weakness. Next morning, the 21st, the pupils were still minutely contracted, and as she still complained of the pressure on the balls I ordered a weak atropine lotion, at the same time advising her to go out for a drive. On the morning of the 22nd she told me that after her drive, and before using the atropine, the weight in the head and the pressure on the eyeballs passed off, and that she felt stronger and better. The pupils were now pretty fully dilated after two applications of the atropine lotion. When I saw the patient on the 20th I was much astonished at the effects produced by a comparatively weak solution of eserine, and after reassuring myself by an examination of the prescription that no mistake had been made in ordering it, I thought that possibly the unusually vigorous action of the drug might be due to the constitution of the patient, who was exceedingly susceptible to the action of some nervine excitants. A visit to the druggist who dispensed the prescription fully explained the matter, however, for it appeared that by mistake he had made the solution of the strength of one grain to the *drachm* instead of one grain to the *ounce*. I have thought that this case might be worth recording, as such an accident cannot often occur, and as the symptoms reminded one more of an overdose of strychnine than one of its antagonistics, the Calabar bean. It appears, however, that in poisoning by physostigma muscular twitchings and tremors often take place before relaxation sets in.

ABDOMINAL SECTION FOR PYO-SALPINX AND SUBPERITONEAL MYOMA; SUBSEQUENT HÆMORRHAGE, REQUIRING RECOURSE TO HYSTERECTOMY; RECOVERY.

By GEORGE ELDER, M.D., C.M. GLAS.,
SURGEON TO THE SAMARITAN HOSPITAL FOR WOMEN, NOTTINGHAM.

MRS. R——, aged forty-two, living in Nottingham, had been an out-patient of the Samaritan Hospital for Women off and on for many months, complaining not so much of pelvic troubles as persistent and severe gastric symptoms, always aggravated by movement, sexual intercourse, and menstruation. These symptoms were nausea, occasionally sickness, and extreme pain after food; and so much had the reflex mischief overshadowed and masked the cause that several practitioners had treated her for stomachic ulceration. The pelvic trouble was diagnosed a considerable time before the consent of the patient could be obtained to the operation, and it was only after treatment by rest &c. had been long and fairly tried that the pains and induced weakness brought her to see the necessity of having something of a radical nature performed.

On Nov. 1st, whilst under the influence of ether, abdominal section was performed, and a firmly adherent left pyo-salpinx removed, and also a myoma about the size of a Tangerine orange, with a long thin pedicle, which was transfixed and tied by a Staffordshire knot. In tightening the silk a crack was made in the peritoneal coating of the uterus, from which oozing took place. Before the completion of the operation this was stopped by sponge pressure, but a drainage-tube was placed in position, to register, so to speak, the condition afterwards. Several times during the day recently effused blood, in no considerable quantity, but still showing no disposition to cease, was withdrawn by the syringe, and in the evening the abdomen was again opened. Ineffectual attempts to arrest the oozing by means of the actual cautery and the continuous suture were made; so after tying off the left broad ligament no difficulty was found in getting the wire of Koeberlé's serre-nœud round the cervix, and constricting it sufficiently to stop all hæmorrhage.

A good stump was obtained; the cervical canal was thoroughly scooped out and swabbed with strong carbolic acid; pedicle pins were applied, and the abdominal wound brought together and well round the stump, no drainage-tube being used. After rubbing the surface of the stump thoroughly with solid perchloride of iron, it was dusted with iodoform, and this was continued almost entirely till the clamp came off on the seventeenth day. The patient made a very good recovery. The highest temperature registered was on the evening of the fifth day, when it was 100·9°. On Jan. 9th she was up and getting about the house, with a small granulating sore left, which was rapidly lessening.

Remarks.—The prominence of the reflex symptoms was in this case the reason of mal-diagnosis and misdirected treatment, as it is in many others, on account of the insufficient appreciation which exists of the close intimacy there is between pelvic troubles and gastric disturbance. One very serious defect of Koeberlé's clamp came out very markedly in this case, and this is the impossibility of sufficiently constricting a thin stump by its means. A modification with an endless screw would be a great gain, and Mr. Lawson Tait's practice of removing it after a few days must of necessity do much to lessen the pain to the patient and to minimise the risk.

Nottingham.

ACUTE GASTRIC ULCER; HÆMATEMESIS; MELÆNA; FISTULA IN ANO; DROPSY; RECOVERY.

By WILLIAM FRASER, M.B. DUB.

ALBERT K——, aged thirty-seven years, a wheelwright, of short, stout build, with a good "corporation," a good liver and moderate drinker, (beer or cider), left work on the evening of Dec. 31st, 1885, complaining of a severe pain across the bowels. This was an old complaint of his, but now it seemed sharper than usual. When seen, the pain was just below and under the end of the sternum, ranging across and around the two sides; tender on pressure; bowels costive and very flatulent; tongue something like a ploughed field, with a dirty greenish brown fur on it. He continued to get worse. Vomiting set in; would eject any and everything, and was in great pain till the stomach was emptied. This pain coming on immediately after food made me suspect that I had to deal with an ulcer of the stomach, and to that I pointed my treatment. Things did not improve. Some days the man felt better and quiet, then went back to the old state. The pain continued, with vomiting now and then, and he lost flesh fast. His face was the picture of misery, and was getting haggard. His tongue remained the same, but looked glazed. On Jan. 28th, 1886, I suggested a consultation with Dr. Ramsay of Torquay, who agreed with my diagnosis. The patient was in great pain on the 29th and 30th, which seemed more violent and less controllable than before, but next day was easier. On Monday, Feb. 1st, about 2 P.M., I was suddenly called, and found him lying stretched on the floor, with three ordinary-sized chamber vessels nearly full of a reddish-black treacly fluid, having a horrid stench; two came from the bowels, and one from the stomach. He was at once placed in bed. He was quite cold, pallid, pulseless, and speechless—more dead than alive. Now came the critical period of the case. I prescribed lead (half a grain) and opium (quarter of a grain) every hour for two days and nights, then every three or four hours if required; ice both to suck and to be applied to the stomach. The watching and anxiety during this week cannot be described; it was like watching the dead, and at times it was even hard to say that he was living. The melæna did not return, but the hæmatemesis continued till 5.30 A.M. of Feb. 4th: he was now better, the pain had ceased, and things seemed favourable, when on the morning of the 9th he threw up some acid material, and at 11 A.M. he again vomited blood, this time fresh, which continued all that day and the next. The end seemed to have come; still we fought against it, and he again rallied. When seen on Feb. 12th the bowels had not been open for the previous ten days. I ordered an injection of a pint of warm gruel; he at first passed about a tablespoonful, but a little time afterwards a quantity of bloody watery material came away. I can best describe the amount by giving his wife's words: "I had a pair of blankets, a small blanket, a large quilt four or five times doubled, and right through the bed-tick, saturated." He remained in a stupor all the afternoon and night, but towards the morning he rallied again and went on to all appearances *in statu quo*. During April he improved; there was no more hæmorrhage, no pain, and the vomiting had ceased. He had been for the last few days complaining of pain about the rectum, when on examination I found that the poor fellow had added a fistula to his previous troubles; it did not communicate with the rectum, and was about an inch and a half deep; the pain of this dulled the ulcer, which had been progressing very well—in fact, healing up. This fistula with ordinary care and boric acid compresses healed up in due time, so that on April 24th he got downstairs for the first time. General dropsy now supervened, which was due to debility, for as he became stronger this disappeared. Convalescence was very slow, he being reduced to a skeleton. On June 16th he was sent to Brixham for change of air, and on July 12th he resumed work.

The treatment pursued during this long illness and the few headings I give do not represent the amount of medical and dietetic care he required, for, as everyone knows, the number of changes rung during an acute illness is legion. At the outset we used bismuth both solid and the liquor, with dilute hydrocyanic acid and nux vomica, sometimes adding morphia or chloral. Blisters were applied to the stomach, and then dressed with morphia ointment. The treatment for the hæmorrhage I have stated above. Later on iron and arsenic were given for fully three months.

Ashburton.

PRIMARY HUNTERIAN CHANCRE OF THE CHEEK.

By H. MITCHELL, B.A. CANTAB., M.R.C.S.,
SURGEON, ARMY MEDICAL STAFF.

THE following case may be of sufficient interest to justify its publication in THE LANCET.

Early in December last a soldier twenty years of age was admitted into hospital with an ulcer in the middle of the right cheek. In character this ulcer was circular, about the size of a sixpence, shallow, clean cut, but the edges not

Digitized by Google

undermined; the surface had a glazed appearance, and secreted a very little watery discharge; its base was surrounded by slightly indurated tissue, which was somewhat inflamed. At the angle of the jaw on the same side was an enlarged gland, not inflamed, about the size of a bean. As the situation of the ulcer corresponded with the position of the chain of the man's helmet, it was thought probable that either the metal of the helmet chain or some substance used in cleaning it had irritated an abrasion on the cheek and so caused the ulcer. The man had no constitutional symptoms. The ulcer was considered to be a poisoned wound, and treated accordingly, first with poultices and hot fomentations, then, when the inflammation had subsided, with diluted red oxide of mercury ointment. In less than three weeks it had quite healed; the slight amount of induration at its base had disappeared; the gland, however, remaining as before, and showing no signs of inflammation. The man was about to be discharged from hospital, and was being examined as to his general condition for this purpose, when a copious rash was seen on his chest, back, and abdomen, extending also to the arms. The rash was mainly papular, but squamous and roseolar in places, and markedly polymorphic; in appearance and colour it was undoubtedly a secondary syphilitic eruption. There was no previous history of syphilis, or any appearance or traces of a sore in the usual situations, and the man stated that he had never had one. The patient was kept in hospital and treated with perchloride of mercury and small doses of iodide of potassium, and by Jan. 20th the rash and the enlarged gland were nearly gone.

The interesting points of this case are—(1) the very unusual situation of the infecting sore; and (2) the early appearance of secondary symptoms, which is probably accounted for by the very free blood-supply to the part. The sore was probably caused by an abrasion on the cheek becoming accidentally poisoned by syphilitic virus.

Portland.

ON THE INFLUENCE OF SALICYLIC ACID UPON ACUTE RHEUMATISM.

By T. F. RAVEN, L.R.C.P. LOND.

IN the treatment of acute rheumatism with salicylate of soda or potass very different results are obtained. Sometimes the remedy acts in a wonderfully satisfactory way, and in a few hours the patient is free from pain, and in a few days convalescent. At other times, but fortunately less frequently, the drug produces no beneficial effect whatever. Until lately I have been at a loss to distinguish the cases amenable to treatment with salicylic acid from those which give no results, but a recent experience has given me a clue which may possibly be of some value. During the prevalence of an epidemic of membranous tonsillitis in an institution, three severe cases of acute rheumatism, with cardiac complications, presented themselves, certainly resulting from the prevalent poison. In the treatment of these cases salicylate of soda entirely failed either to reduce temperature, to relieve pain, or to arrest the disease. I was so struck with the failure of the drug in three successive cases that the possibility occurred to me of explaining it by the origin of the disease. It may be that the acute rheumatism which results from zymotic influences is different in its nature, though not apparently in its symptoms, from that which arises from cold and damp.

AN ENORMOUS CALCULUS.

By E. COLSON, M.R.C.S.,
SURGEON-MAJOR.

JABTER NASSIR, a Bedouin Arab who had come eight days' journey to Hodeedah, and thence by sea to Aden, presented himself at the Civil Hospital for treatment for calculus of the bladder. On Feb. 1st, when on the operating table, the stone was carefully examined with the sound and per rectum. Having come to the conclusion that the stone was a very large one, I determined on the supra-pubic operation. The bladder was injected with twenty ounces of warm water, which raised it well above the pubes. An incision about three inches in length was made vertically above the pubes, and the parts carefully dissected down until the veins above the bladder were exposed. Whilst separating these with a director, it passed through into the bladder, which appeared soft and friable. The finger was immediately introduced through the opening, and an enormous stone was found to occupy the cavity of the organ. To extract this the original incision had to be much enlarged, and with great difficulty the stone was removed. This was found to weigh 9¼ oz. avoirdupois, and measured 7½ in. in its horizontal and 8½ in. in its vertical circumference. A large catheter was fastened in the bladder per urethram, and the wound in the skin closed and dressed antiseptically. The man recovered well from the immediate effects of the operation, and was doing well also in the evening. I regret to say he died suddenly on the following morning. No post-mortem examination was made, as the Arabs object to such a measure. The distension of the bladder alone appeared to answer every purpose, as the peritoneum was not seen from first to last. The man said he had had the stone for ten years, but as he would be entirely ignorant of means of computing time, such a history is quite untrustworthy.

ST. BARTHOLOMEW'S HOSPITAL.

SARCOMA OF THE TONGUE; REMOVAL OF HALF OF TONGUE RECOVERY; REMARKS.

(Under the care of Mr. BUTLIN.)

CONNECTIVE-TISSUE tumours of the tongue are so very rare that the account of the following growth will be read with great interest. Appended to the remarks will be found references to other tumours of this part, and the list is not a large one. The diagnosis has to be made from gumma, and in order to do this it is necessary to give large and increasing doses of the iodide of potassium. This treatment was fully tried in this case, and the swelling punctured, without improvement. For the following notes we are indebted to Mr. Knight.

C. J——, aged forty, car-driver, was admitted into Rahere ward, Oct. 12th, 1886, with a swelling of the left half of the tongue. The patient first noticed a soreness about the middle of the left side of the tongue two months ago, and a swelling at the same spot one month ago. The swelling had increased rapidly. He had had no pain except on eating; he never had syphilis; he had smoked cigars, but never a pipe. Always enjoyed good health. Family history good.

On admission he was a healthy-looking, strong man. Situated in the substance of the left half of the tongue was a smooth, soft, elastic swelling, bulging on the upper and under surface of the tongue, and about the size of a fives ball. It did not extend across the middle line, but reached from the junction of the anterior and middle thirds to the back of the tongue. The latter could not be protruded from the mouth. There was no ulceration. A hard and enlarged gland was felt beneath the jaw in the submaxillary region. The teeth in the upper jaw were mostly in a decayed condition. Under the impression that the tumour contained fluid it was punctured five days previously, but only blood exuded. He was ordered ten grains of iodide of potassium three times a day.

Oct. 16th.—Fifteen grains of the iodide were ordered. No change in swelling.

19th.—Iodide increased to twenty grains. Tongue can be protruded a little further.

22nd.—Twenty-five grains of the iodide to be taken. No further change.

23rd.—The under surface of the tongue was painted with a 4 per cent. solution of cocaine and the swelling again punctured. A few drops of blood only exuded.

25th.—Thirty grains of iodide of potassium ordered.

Digitized by Google

28th.—No material alteration has taken place in the swelling since admission.

After consultation with his colleagues, Mr. Butlin decided to make an incision into the tumour, and if it should prove to be malignant, to remove it. Accordingly, on Nov. 5th the patient was placed under the influence of an anæsthetic, and Mr. Butlin cut into the tumour, which proved to be solid. He then cut through the mucous membrane in the median line above and below the tongue, and tore through the muscular tissue from the tip to the back. The left half of the tongue was then snipped through with scissors behind the tumour, all vessels being clamped as soon as divided. There was a good deal of hæmorrhage. The vessels were secured with silk ligatures, and the wound dusted with iodoform. The gland under the jaw was not removed. The growth on section proved to be a soft white tumour about the size of a fives ball; it was circumscribed, with the appearance of a capsule at one point. The microscope showed it to be a small round-celled sarcoma (lympho-sarcoma). Some hæmorrhage ensued five hours after the operation, and two small vessels were ligatured; the general oozing was stopped by the application of some styptic charpie.

Nov. 6th.—Temperature 99·8°; pulse 136. Fed, by a tube passed through the nose three times a day, with eggs, milk, essence, and beef-tea. Wound dusted frequently with iodoform; very little swelling.

8th.—Temperature 99·6°; pulse 96. Takes a little iced milk by the mouth. He is still fed by the tube.

10th.—Evening temperature 100·6°; to-day 98°; pulse 86. The gland in the submaxillary region is smaller. Takes liquid food, and is fed twice a day by the tube.

15th.—Got up for the first time. Wound nearly healed. Takes all his food by the mouth. Temperature 98·8°.

17th.—The enlarged gland has entirely disappeared. Wound healed. Talks fairly well, and takes solid food.

On the 19th the patient was discharged from the hospital. Three weeks afterwards he was in good health, and could talk plainly. There was no glandular enlargement, and no sign of recurrence.

Remarks.—The above case differs in some important points from those previously recorded—namely, in the age of the patient, the rapid growth of the tumour, and the healthy condition of the mucous membrane over it. The tumour, though not encapsuled, was perfectly circumscribed. The enlargement of the submaxillary gland was probably due to pressure upon the duct.

Previous cases.—Jacobi: *American Journal of Obstetrics*, 1870. Godlee; "Holmes's System of Surgery," vol. ii., art. "Tongue," by Barker. Hutchinson: Medical and Chirurgical Transactions, vol. lxviii., p. 311, 1885. Eve: Pathological Transactions, vol. xxxvii., p. 223, 1886.

CHARING-CROSS HOSPITAL.

FRACTURE THROUGH SARCOMA OF FEMUR; SECONDARY DEPOSITS IN SKULL AND CLAVICLE; DEATH; NECROPSY.

(Under the care of Mr. BELLAMY.)

THIS case presents several points of pathological interest, and is of value in showing how the real cause of fracture and of the non-union was unsuspected or overlooked. For the following notes we are indebted to Mr. H. L. Arnim, ward clerk.

Fred L——, aged forty-seven, was a sufferer from sciatica and rheumatism, and walked rather lamely with a stick. On Nov. 9th he was at Shaftesbury-road station, and on putting his walking-stick to the platform it slipped through a crevice. He fell heavily forward, at the same time putting out his left leg to save himself. He heard and felt something snap in the limb, and felt a sudden pain. Patient was unable to rise to his feet or, indeed, to bear any weight upon the left limb, and was brought to the hospital in an ambulance. The fracture, which was in the middle third of the left femur, with very little displacement, was put up in a long Liston splint with a starched bandage.

Nov. 18th.—No pain; temperature normal.

28th.—Progressing favourably.

Dec. 1st.—There is no pain; patient feels quite comfortable.

14th.—A bedsore about three by two inches has formed over the right buttock. It is dressed with boracic ointment.

21st.—A swelling of about the size of a Tangerine orange has appeared over the left side of the scalp. On an exploratory puncture being made, the contents were found to be blood. Over the anterior aspect of the inner third of the clavicle is a painful swelling occupying about two inches of the anterior aspect of the bone. The pain is of a lancinating character, worse at night. Skin not discoloured. A plaster-of-Paris bandage substituted for the starched bandage.

26th.—Patient got up yesterday and the day before.

27th.—The plaster-of-Paris bandage has been removed; there is much pain at the seat of fracture.

28th.—Skin over back broken; painted with balsam of copaiba.

Jan. 4th.—Patient put under ether. Ends of ununited bone rubbed together. Leg put up on long Liston splint.

6th.—The clavicle is better; swelling and pain decreased; fracture still painful.

18th.—Thigh put up in plaster-of-Paris. Sore on back size of palm of the hand. Slough separating and leaving ragged ulcer, which is discharging freely. Dressed with iodoform and boracic dressing. The sore extends from the tip of the coccyx to the upper border of the sacrum.

Feb. 2nd.—The patient is very emaciated; complains of loss of appetite. Slight sore appearing under right angle of the scapula. Still dressed with iodoform and boracic dressing. Leg put in plaster again.

21st.—For the last eight or ten days the patient has been in a half-conscious condition; mind wanders occasionally. Sore on back getting larger; edges of the ulcer undermined. Ulcer presents an indolent appearance. Patient's appetite bad; very weak. The patient died this evening at 11 P.M.

Necropsy.—Body emaciated; no rigor mortis. Abdomen (superficial view) normal. Heart distinctly fatty. Liver fatty; no secondary nodules; weight 3 lb. 8 oz. Kidneys normal. Spleen rather soft; post-mortem change. Apex of right lung emphysematous; base congested with purulent fluid passing from the bronchi. Left lung congested and slightly emphysematous; rest same as right. The convolutions of the brain were marked on the left side by a tumour pressing on them; the dura mater was not destroyed, and the tumour was not adherent to the brain substance. There was a large ovoid swelling on the left thigh at the junction of the upper and middle third; the upper and lower parts could be freely moved on each other, with a peculiar crackling distinctly felt by the hand. On removing the femur this ovoid swelling externally looked very much like brain tissue, being convoluted; and on section it was the same, but it cut much harder than brain tissue. There was a tumour on the left parietal region of the skull. On dissection it was beneath the pericranium, and the dura mater was intact on the internal surface; the whole of the parietal bone for the diameter of two inches and a half being replaced by a soft, brain-like tumour of the same nature as the tumour of the femur. The mass occupied the anterior superior portion of the parietal bone, extending about half-way from the sagittal suture down the bone, and less than half way back from the fronto-parietal suture. It projected about an inch and a half from the surface, and was almost flat inside.

MANCHESTER ROYAL INFIRMARY.

HYDATID CYST OF LIVER; RESECTION OF RIB; REMOVAL OF CYST WALL.

(Under the care of Mr. WHITEHEAD.)

WE are indebted to Mr. Brazil for the report of the following case.

E. W——, a slightly-built and somewhat delicate-looking woman, aged thirty-two, was admitted into the surgical wards on Sept. 18th, 1886. The patient gave the following history of her trouble. In January 1885, she had a slight attack of pneumonia, and on recovery was left with a pain in the right side, which has continued with varying intensity up to the present date. About six months previous to admission she appears to have had an attack of jaundice, and at the same time some swelling of the lower extremities. About two months after this she was admitted into the Bowdon Consumption Hospital, where she remained three weeks. While there an aspirating needle was introduced into the hepatic region, and some clear fluid withdrawn. From Bowdon she came to the Manchester Royal Infirmary, and was admitted into the medical wards. Here she remained about three months, after which she was transferred to the surgical side. While in the medical wards she was tapped twice; on the last occasion 15 oz. of fluid were withdrawn. The fluid was clear, contained abundance of chlorides, but no albumen. No hooklets were dis-

Digitized by Google

covered on either occasion. Patient had lost flesh considerably during her stay in hospital.

Her condition on admission to the surgical ward was as follows: On physical examination some fulness was perceptible over the hepatic region. The liver dulness was markedly increased, and was found to extend upwards as high as the third intercostal space, and downwards for half an inch beyond the costal margin. There was slight tenderness on pressure. The patient complained occasionally of slight pain in the right side radiating into the right shoulder.

Operation.—On October 4th the patient was placed under chloroform, and an incision about two inches long was made parallel to and slightly below the right costal margin. The various layers of the abdominal wall were divided successively and the anterior border of the liver brought into view. No cyst, however, was found. The wound was now carefully stitched up again, each layer being sutured separately. From this operation the patient made a good recovery.

On Nov. 13th a second operation was undertaken. An incision about three inches long was made over the eighth rib in the mid-axillary line, and a portion of the rib about an inch in length resected, the periosteum being left. After cutting through a layer of thickened pleura a large cavity was reached, from which about twenty ounces of thick yellowish-brown fluid escaped. This fluid was afterwards found to be loaded with albumen and to contain distinct hooklets. The cavity was lined with a distinct homogeneous membrane of a bright yellow colour, about $\frac{1}{16}$th of an inch thick, and rather soft and friable. By careful manipulation the cyst wall was entirely removed. Numerous daughter cysts were removed at the same time, some coming away with the fluid, some with the cyst wall. After removal of the cyst the cavity was thoroughly washed out with boracic lotion and a large drainage-tube inserted.

Nov. 14th.—The patient passed a fairly good night. Temperature 98°. The dressings were soaked through with fluid highly coloured with bile. Cavity washed out as before. The patient is taking eight ounces of brandy a day.

20th.—The discharge is still very profuse and deeply bile-stained, but is now distinctly purulent. The cavity is washed out daily with boracic lotion. Portions of daughter cysts occasionally come away with the discharge.

December 6th.—The temperature last night went up to 101·6°, and the dressings were found to be saturated with blood. On examination it was found that the hæmorrhage proceeded from the cavity. This was washed out with boracic lotion and fresh dressings applied. This morning a quantity of blood was found on the dressings, and on syringing the cavity a few clots came away.

7th.—Temperature this morning 97·6°. More blood was found on the dressings, and a few more clots discharged.

10th.—There has been no more bleeding, and the temperature remains normal. The discharge is small in quantity, and consists of perfectly healthy pus. The cavity now holds rather more than an ounce of fluid. After this the patient continued to make a good and quite uneventful recovery. When seen in February, she was looking stouter, was in better health altogether than before the operation, complained of no pain, and ate and slept well. The wound in the side had not healed, but the discharge was perfectly healthy and trifling in amount.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST.—The seventy-third annual court of governors of this institution was held on the 15th inst., the Lord Mayor presiding. From the report it appeared that the financial condition of the hospital during the past year has been, on the whole, encouraging, but much remains to be done before it can be pronounced satisfactory. In order to carry on the work now in hand an annual income of between £4000 and £5000 is required, and when all the wards are in full work the annual expenditure will not be less than £7000. The present income from subscriptions and dividends amounts to less than £2000. These, added to the donations and collections last year, produced a general income of about £3100, exclusive of legacies. The Right Hon. Lord Charles Bruce has accepted the office of President of the Hospital.

Medical Societies.

ROYAL MEDICAL & CHIRURGICAL SOCIETY.

Obstruction of one Ureter by a Calculus, associated with complete Suppression of Urine.—Sacculated Kidney containing Calculi with Disorganisation of the other Kidney, and associated with complete Suppression.

AN ordinary meeting of this Society was held on Tuesday last, Mr. G. D. Pollock, F.R.C.S., President, in the chair.

Mr. R. J. GODLEE read a paper on a case of Obstruction of one Ureter by a Calculus, accompanied by complete Suppression of Urine. Up till June 4th, 1884, the patient, a medical man, who was then thirty-one years old, had enjoyed good health, with the exception of an attack of blood-poisoning following a poisoned wound whilst he was a student in 1872, and occasional attacks of colic, supposed to be intestinal, which were relieved by morphia. He was then attacked with frequency of micturition and pain in the bladder. A week later sickness began and right renal pain, with fever and hæmaturia. There was pus in the urine. After a few days these symptoms subsided, but they soon returned and became worse. Intense tenderness appeared in the right loin, and the urine became highly albuminous, and contained large numbers of hyaline and granular casts, as well as masses of bacteria, but it was never putrid. On July 13th a deep-seated perinephritic abscess was opened. The kidney could not be discovered. The casts disappeared completely from the urine, and the albumen diminished to a very small quantity. No urine escaped from the wound, which healed without trouble. The patient after this remained well, with the exception of occasional attacks of colic, till Dec. 10th, 1885, when an attack of great severity set in, for which he took several hypodermic injections of morphia. On the 14th complete suppression of urine occurred, and lasted a week. No operation was undertaken, because it was assumed that there was only one working kidney, the ureter of which was blocked. On the 19th, however, the left kidney was felt and punctured, but the pelvis was found to be empty. On the 21st he began to pass highly albuminous urine, and the amount and character of this became more and more normal; but he did not rally, and died exhausted on the 26th. At the necropsy the right kidney was found to be dilated into a loose bag of pus, and a stone was impacted half way down its ureter, which was dilated throughout its whole extent. The left kidney was large and comparatively healthy, but showed signs of chronic interstitial nephritis; the pelvis and ureter on this side were normal. The interest of the case depends on the following facts: 1. That an abscess around a diseased kidney may cause intense albuminuria and the presence of copious casts, even though the other kidney be comparatively healthy. 2. Irritation of such a diseased kidney (aided perhaps by the presence of a certain amount of morphia in the system) may cause complete suppression, similar to that caused by complete obstruction of the ureters, and not like that occurring in Bright's disease. 3. Though the stone was impacted halfway down the ureter, this tube was dilated throughout its extent.

Mr. R. W. PARKER read a paper on a case of Suppression of Urine, following injury to a sacculated kidney containing calculi, the other kidney being entirely disorganised. S. C.——, aged thirteen, a well-built boy, fell over some steps and struck his right side in the region of the kidney. Up to this accident he was said to have been quite well. The fall caused him great pain, and he had some difficulty in getting home. He went to bed, and remained there for some days. Two days after the accident the boy "passed blood instead of urine." He vomited frequently, and suffered considerable pain at intervals, and the urine continued to contain blood. At the end of a week he appeared to have regained his usual health, but his symptoms all recurred at the end of another week, and he was brought to the hospital, where he remained three weeks, and was then discharged apparently well. Examination at this time failed to detect anything abnormal with or about the kidney. He had some slight pain from time to time, and for two or three days after admission the urine contained blood. In two months'

Digitized by Google

time the boy was brought back to the hospital, with recurrence and aggravation of all his symptoms. It was then elicited, after closely questioning his mother, that the lad had had similar but less pronounced symptoms for twelve months past. On his readmission he was found to have a large, tense, elastic swelling in the region of the right kidney, extending as far forwards as the umbilicus. This was diagnosed as a traumatic hydronephrosis, and was tapped several times on account of the pain and discomfort which it caused. As it refilled rapidly, it was exposed in the loin and a free incision made into it. During the first five days in the hospital the boy passed an average of forty-five ounces of urine; in the next four days this average fell to thirteen ounces a day; on the tenth day only one ounce was passed. Unmistakable signs of uræmia now set in, and the boy died four days subsequently. The post-mortem examination showed that the left kidney was quite disorganised, and converted into a mere sac, in which one large and several small calculi were found. The right kidney (the injured one) was greatly hypertrophied; the calyces were much dilated, in one of these a large calculus was found, and in others smaller calculi. A small calculus was found in the right ureter, at the level of the brim of the pelvis. The author remarked on the awkward nature of the hydronephrotic sac as a complication; it prevented the finger reaching the front of the kidney, and the examination of the pelvis and ureter through the incision in the loin. It was thus impossible to make quite sure of the diagnosis. Calculus was suspected and the kidney was punctured in several places without result. When the urine diminished in quantity, less importance was attached to this fact than it merited, judged in the light of the post-mortem evidence; it was thought the urine found its way into the hydronephrotic sac, and that the diminished quantity, voided per urethram, represented the product of the other kidney. The treatment adopted was referred to, and the question was raised whether any surgical treatment directed through the loin could have dealt with this case successfully.

Mr. BELLAMY showed a specimen taken from a young man aged twenty-three. In this case it was difficult to reach the kidney, and altogether the case had considerable resemblance to that described by Mr. Parker.—Dr. S. COUPLAND said that the paper by Mr. Godlee raised questions of much moment in renal pathology. Was it possible that disease about one kidney could determine suppression of function in the other, presumably healthy, kidney. He inquired for further information as to the amount of disease found in it. Any irritation in the body would have a greater effect on a kidney which was the seat of some morbid change. The fact that the "good" kidney was slightly cystic and the seat of a little interstitial nephritis would predispose it to cease secreting. He inquired on which side of the body the patient experienced the last attack of renal colic preceding suppression of urine. He ventured to question, in view of the variety of clinical aspects of uræmia, whether it was not too much to endeavour to distinguish between the obstructive and non-obstructive kinds by a reference to mere symptomatology.—Mr. W. A. MEREDITH thought that the case illustrated the advantages of performing an abdominal exploration before determining on a lumbar incision. It might have been possible to have felt the stone in the right ureter.—Mr. HOWARD MARSH said that it must be admitted that in the three cases mentioned a defective diagnosis had been made. He thought that this circumstance, amongst others, was an argument in favour of an abdominal exploration. One point in renal surgery seemed to be coming to the front; that many stones were not to be reached from the loin. Our progress seemed to be in the direction of admitting the wisdom of an abdominal examination. Reference was made to the case read by him before the Clinical Society.[1]—Mr. A. A. BOWLBY raised with Dr. Coupland the question whether disease of one organ could cause suppression of urine in a sound kidney. He related the case of a man who sustained an injury in the loin, which was followed by sickness and hæmaturia. A urethral stricture gave some trouble at first, but after the catheter was tied in complete suppression of urine for thirty-six hours followed, and but twelve ounces were passed in the next twelve hours. The urine was then healthy, and had not a faint trace of albumen. As bearing on the question of the influence of injury on a subject affected with Bright's disease, he mentioned the case of a man who had a compound fracture of the tibia, and died soon after. It was found that there was evidence of chronic interstitial nephritis, on which an acute suppurative nephritis had supervened, probably as the result of the severe accident.—Dr. R. D. POWELL inquired what was the cause of the perinephritic abscess. Seeing that a perinephritic abscess existed, he asked whether it would be good surgery to attack it through the median line of the abdomen. He considered it would be bad surgery, from a physician's point of view, to perform the abdominal section in the presence of urine albuminous and containing casts. He also considered that it would be practically impossible to determine the state of the parenchyma of the kidney by mere palpation, or indeed by any other method of physical examination.—Mr. A. E. BARKER rather agreed with the views of Dr. Powell, and especially in the case of a perinephritic abscess. If a stone be impacted in the upper part of the ureter, and could be returned to the pelvis, a nephrolithotomy from the loin would still be necessary. In many advanced cases the lumbar nephrotomy would be most suitable. But he did not deny that there were cases in which the abdominal section would be not only justifiable, but more advantageous. The case of a young woman was narrated in which a stone was removed by the lumbar operation from the infundibulum of the renal pelvis; but it appeared that the stone had been there so long that it had led to an apparent cicatricial thickening of the upper end of the ureter; a permanent lumbar fistula was necessary. The patient remained well and suffered no discomfort. — Mr. MEREDITH said he only advocated abdominal exploration as a means of diagnosis. — Mr. BARWELL remarked on the importance of estimating the amount of urea discharged daily. Important information might thus be gained, and might be of service in determining the advisability of operation.—Dr. OGIER WARD said that much valuable information might be obtained by catheterising the ureters, a method which would allow of the separate examination of the urine discharged from each kidney.—Mr. GODLEE said there was some disease in the comparatively healthy kidney, and he did not contend that disease about one kidney could lead to cessation of function of the other kidney if the latter be perfectly sound. He did not venture to say whether we dwelt too much upon the distinction between obstructive and non-obstructive anuria. The stones in the kidney were the probable cause of the perinephritic suppuration. He considered that a hand in the abdomen could not determine the healthiness of a kidney. Reference was made to the invention some years ago of an instrument shaped like a lithotrite for the investigation of the urine from the ureters.—Mr. R. W. PARKER said that in his own case an abdominal exploration would have determined the state of the diseased kidney. The stone, too, would have been detected in the ureter.

MEDICAL SOCIETY OF LONDON.

Incision of Swollen Optic Nerve-sheath.—Solvent Treatment of Renal Calculus.—Intussusception.—Congenital Defect in Diaphragm.

AN ordinary meeting of this Society was held on Monday last, Dr. Hughlings Jackson, F.R.S., President, in the chair.

Mr. BRUDENELL CARTER read a paper on a case of Swollen Optic Disc, in which the sheath of the optic nerve was incised behind the eyeball. After alluding to the attempts of De Wecker and Power, he discussed the pathology of swollen optic nerve, and contended that it was primarily dropsical and only secondarily neuritic. He considered that there was a descent of fluid from the subarachnoid space to the space between the dural and pial sheaths of the optic nerve; the nerve was compressed by the fluid and the venous circulation was impeded. The results varied in different cases. Mr. Carter contended that incision of the nerve-sheath and evacuation of the contained fluid, if accomplished at or before the commencement of impairment of vision, would save the patient from blindness. The case related was that of a young woman who had impaired sight and headache of ten days' duration. The left optic disc was much swollen. Under iodides and mercury no improvement resulted. The disc swelled still more; hæmorrhages and patches of exudation also appeared; and, with the assent of Dr. Hughlings Jackson, Mr. Carter

Digitized by Google

decided upon an operation which he first practised on the dead subject. The external rectus muscle was divided; the eyeball then rotated inwards; the sheath of the optic nerve was exposed and opened, and gave exit to the contained fluid. Recovery was uninterrupted, the patient was at once relieved of headache, which did not return for a month, and in ten days after the operation the swelling of the optic disc was found to have diminished by one-half. Further recovery has resulted. Mr. Carter claimed that the operation could be performed with certainty and without danger, and he urged its adoption in all cases of cerebral disease in which sight was beginning to be impaired.—Dr. HUGHLINGS JACKSON remarked that the case was of great interest because of the monocular optic neuritis and of the blindness of the temporal half only of the visual field. He expressed his approval of the operation in the case mentioned, and considered it resulted in a great success.—Mr. JULER was much interested in the operation, and congratulated Mr. Carter on the result.—Mr. ASTLEY BLOXAM thought that opening the sheath of the optic nerve might act as a drain on the subarachnoid space in cases of tubercular meningitis associated, or not, with optic neuritis.—Dr. HERRINGHAM inquired whether Mr. Carter would operate on cases of uræmic neuritis.—Dr. S. WEST asked whether the operation would be performed on one or both sides in cases of double optic neuritis, and whether many cases of optic neuritis became blind.—Dr. ORMEROD spoke of the effect of this operation on the actual cerebral condition: the headache appeared to be relieved in the case related. The operation might be beneficial in preventing blindness in those cases which ultimately recover from the disease which caused the optic nerve swelling.—Mr. B. CARTER considered that true neuritis could not exist without affecting the function of the optic nerve. He would not be disposed to incise the sheath in cases of granular kidney, nor in other cases unless there was defect of vision.

Dr. RALFE exhibited a specimen of Renal Calculus passed after six weeks of solvent treatment. It was oat-shaped, eroded on the surface, measuring one-third of an inch long, and weighing three grains and a half. It was composed chiefly of oxalate of lime, with a few crystals of uric acid scattered over the surface. The remedies employed consisted of lithia and turpentine in a mixture, with Dover's powder at night. The patient was also directed to drink at least three pints of filtered rain-water daily. Under this treatment the urine, which at first had a specific gravity of 1025 and contained much blood and pus, became clear, and the specific gravity fell to 1014, whilst the attacks of colic diminished. Dr. Ralfe's method differs from that proposed by Sir William Roberts, in that he does not seek to diminish the size of the calculus by chemical solvents—a doubtful and difficult process,—but by checking its growth, by keeping the specific gravity of the urine low, and also by diminishing existing pyelitis to allow free passage to the concretion. Dr. Ralfe observed that there are many calculi small enough to easily slip down a ureter, but are prevented by the swollen condition of the orifice. He illustrated this by a specimen, which had been retained for several days, owing to the patient suffering from gouty pyelitis, though the concretion was quite minute. As soon as the pyelitis was relieved the calculus passed easily. In addition to distilled water and turpentine, Dr. Ralfe spoke highly of benzoate of lithia or potash. He advises recurrence to this mode of treatment: 1. When the calculus is recently formed and is still small, and is retained chiefly by the swollen condition of the mucous membrane of the pelvis of the kidney. 2. In recurrent calculi, the pisiform concretions of elderly people. In these cases the calculi passed before the administration of the remedies are about the size of a pea; after, they diminish to that of a mustard-seed (specimens shown), or cease altogether. 3. In cases when, owing to the obesity of the patient or broken health, nephro-lithotomy is not advisable. In these cases we may hope the distilled water may in time lead to the disintegration of the calculus, as in a case recorded by Dr. Ralfe;[1] whilst the terebinthine remedies undoubtedly diminish the pyelitis and the tendency to colic.—Dr. MAGUIRE considered that it savoured of the irrational to send patients to foreign spas when so much could be done for them at home by the employment of distilled water which contained no salts, and therefore would presumably have a greater solvent action on stone than waters impregnated with salts.—Mr. F. B. JAGGARD said that larger stones had been passed without the treatment, which benefited rather by its diluent than solvent action.—Dr. RALFE said he did believe in a solvent action, and he attached considerable importance to the treatment of pyelitis.

Dr. W. H. ALLCHIN showed a specimen of Intussusception removed from a male infant aged six months. The tumour was of the size of a Cambridge sausage; the jejunum was drawn down so as to be close to the intussusception, which had descended into the rectum. There was a second duplication of the colon, doubtless secondary in time to the primary intussusception.

Mr. ASTLEY BLOXAM showed a specimen of Congenital Opening in the Diaphragm in an infant aged three months; it was situate near the left external arcuate ligament. The left lung had never been expanded; chronic vomiting led to exhaustion. He also showed a case of Plastic Surgery in which a new mouth had been formed.

HARVEIAN SOCIETY.

Extirpation of the Axillary Glands: a necessary accompaniment of removal of the Breast for Cancer.

AT the meeting on March 3rd (Edmund Owen, M.B. F.R.C.S., President, in the chair), the sitting was occupied by a discussion on the above subject.

Mr. MITCHELL BANKS, in opening the debate, laid before the meeting a printed table showing the results of his practice in eighty-two cases. The complete operation as advocated by himself was indeed a very severe measure, and its mortality was very considerably in advance of that of the old incomplete method, in which the axilla was not opened. At the same time, however, his table showed that the duration of life was prolonged, and the recurrence of cancer less seldom occurred; and these results justified the greater risk to which the patient was exposed. The old incomplete operation he condemned as *unscientific* and *useless*. He laid great stress on not allowing the chest wound to remain exposed while the axilla was being cleared, but advocated closure of the wound from below upwards as the operation proceeded; the glands should best be removed by the knife, but enucleated with the aid of the fingers and two pairs of forceps. He did not hesitate to tie and remove portions of the axillary vein, if this last vessel interfered with complete removal of the glands.

Mr. BRYANT thought the operation advocated a very severe one, and its results, as shown by Mr. Banks' tables, disappointing. Theoretically, the complete operation was all that could be desired, but in practice he felt that it was open to criticism. In ordinary cases it might be right to perform the complete operation, but in some cases—e.g., in aged women with ulcerating cancers, and in feeble women possessed of only moderate powers—the incomplete one was justifiable. Speaking from his own experience, the mortality of the complete was but little over that of the incomplete operation. It would seem that the average duration of life after the severe operation was not much greater than after the milder procedure. Statistics showed that after the incomplete operation one-third of the cases lived for six years, and 25 per cent. for ten years and more. It might fairly be questioned whether the complete gave really better results; and, if not, was it justifiable to submit every patient to the greater risk? In his opinion, unless the glands could be easily felt, it was wisest, in dealing with aged or feeble patients, not to open the axilla. He approved of Mr. Banks' plan of closing the wound from below upwards as he proceeded, and likewise of his method of enucleating the glands in preference to removing them by section. No harm came from interference with the axillary vein, though he had only once had occasion to tie that vessel in the course of the operation.

Mr. PICK did not agree with Mr. Banks in his opinion that the operation for removal of the breast for cancer in the usual manner—by the method which Mr. Banks was pleased to call the "incomplete" method—was "useless or worse than useless," even though it did not prolong the patient's life by a single day. It freed the patient from the oppression of a disease which she knew was rapidly approaching a fatal termination, and gave her the chance, and certainly the hope, of immunity from recurrence. It afforded her an interval of health and freedom from pain, instead of a life of anxiety and suffering, and in a certain percentage of cases the cancer returned in some internal organ and

Digitized by Google

afforded the patient a quiet and comparatively painless death, instead of the horrible suffering which an open cancer too often entailed. With regard to the "complete" operation of Mr. Banks, Mr. Pick quite agreed with him that the removal of the disease should be most thorough, and that, in order that this might be so, no heed should be taken to preserve sufficient skin to form flaps to cover the gap left, but that, if necessary, the sore should be left to granulate as an open wound. But he was not prepared to agree with Mr. Banks that clearing out of the axillary space was either necessary or judicious. The proceeding added very materially to the danger of the operation, as shown by Mr. Banks' tables; and in his (Mr. Pick's) experience it was only in a small percentage of cases that the disease recurred in the axillary glands, the cicatrix remaining healthy. He therefore regarded the proceeding as unnecessary, and it was also injudicious as adding to the mortality. Mr. Pick was inclined to attribute the success which Mr. Banks had obtained rather to the very free removal of the breast and surrounding tissues than to the extirpation of the axillary glands.

Mr. BUTLIN said that in the discussion on Dr. Gross's paper, during the meeting of the International Congress in London, he had been inclined to take a similar view to Dr. Gross and Mr. Banks with regard to the removal of cancer of the breast. Since that time, however, he had made a very careful study of the natural history and course of cancer of the breast, and of the cases published by the author of this paper, and had come to the conclusion that the very free removal of the mamma and opening of the axilla, recommended by Mr. Banks in every or nearly every instance of cancer of the breast, is an unsurgical and unscientific proceeding. Besides several minor propositions, Mr. Banks had put forward two main propositions: that the operation should include the entire mamma with the overlying skin and parts beneath in all cases, and that the axilla should be opened, whether enlarged glands could be felt in it or not. Mr. Butlin dissented from both propositions. From the first, because the operation bore no direct relation to the extent of the disease. The tumour was often of small size, and situated in the inner or the lower segment of the breast, and the incisions, instead of being carried equally far from it in every direction, were perhaps three inches from it in one direction, and less than one inch in other directions. Cancer of the breast must be treated in the same manner and on the same principles as cancer of the lip and similar parts; very free removal of the disease, the surrounding textures, the overlying skin, and the fascia over the muscle, if need be; but not removal of parts which were not, and probably never would be, affected. With regard to the second proposition, most surgeons were agreed that the glands in the axilla should be removed if they were enlarged and could be taken away. Mr. Butlin would go so far as to open the axilla in cases in which an indefinite fulness could be felt. But he would not open the axilla in other cases. He had collected notes of 101 cases in which the axilla had not been opened, and 209 cases in which the glands had been removed. The mortality in the first set was 10 per cent., the proportion of women alive and well at the end of three years, 18 per cent. The mortality in the second set was 20 per cent.; the number of women remaining well at the end of three years about 5 per cent. The cases in which there was no affection of the glands, and in which the axilla had consequently not been opened, were by far the best cases for operation, not only on account of the less severity of the operation, but because the disease was less malignant.

Mr. HARRISON CRIPPS thought the profession was much indebted to the persevering manner in which Mr. Banks had brought the subject of the removal of the axillary glands so prominently forward. Though he would not like to make an arbitrary rule that they should invariably be removed, he agreed that in the majority of cases such treatment was indicated. The question to some extent turned on whether or not the opening of the axilla and removal of the glands added greatly to the danger of the operation. According to the experience of St. Bartholomew's Hospital this did not appear to be the case. In the five years from 1863 to 1867, at a period when it was the exception rather than the rule to open the axilla, the mortality after amputation of the breast was as near as possible 11 per cent. Owing, however, to improved methods and better sanitary condition of the hospital, the rate of the mortality during the last five years only amounted to 6 per cent., and, moreover, during this latter period in about half the cases the axillary glands had been removed. In the last year's reports it is especially noted that of thirty-eight cases of amputation of the breast for cancer, in nineteen the axillary glands were also removed, but the rate of mortality was exactly the same—viz., one death in the nineteen cases in which the glands were untouched, and one death in the nineteen cases in which the glands were removed. The high rate of mortality in Mr. Banks' cases appeared to be entirely due to blood poisoning, the result of insanitary surroundings. Mr. Cripps considered that in operating for breast cancer the free removal of skin over the tumour, although it might appear to be supple and not complicated at the time of operation, was of the utmost importance, for it frequently happened that recurrence took the form of cancerous nodules in the skin bordering on the cicatrix, and that this phenomenon showed how often the skin was really infected, and should have been freely removed at the original operation.

The PRESIDENT expressed surprise at the amount of opposition which the important paper, just read, had elicited. He was under the apprehension that surgical opinion was steadily drifting in the direction of opening the axilla and enucleating all discoverable lymphatic glands, whether definitely implicated or not. Often it was impossible to say whether there was axillary invasion or not until the armpit had been opened up. Clearing away the glands was a desirable measure, in that it diminished the risk of subsequent pressure (from secondary malignant enlargement) upon the axillary vein and the cords of the brachial plexus, thus obviating, as he believed, the œdema and neuralgia of the arm so often met with when the glands were left untouched. Probably, also, the removal of the glands might be the means of checking a general invasion of the lymph currents; the risk of remote infections was certainly less if those centres of infection, the glands, were out of the way. The operation was a severe one, but it had the great recommendation of being thorough. He failed to see how an operation for malignant tumour could be complete which did not effect at the same time the cancerous glands associated with that tumour.

Mr. BANKS briefly replied.

MANCHESTER PATHOLOGICAL SOCIETY.

A MEETING of this Society was held on Feb. 9th, Dr. J. Dreschfeld, President, in the chair.

Cystoma of the Ovary.—Mr. W. A. STOCKS showed a preparation of a cystoma about the size of an orange which had passed down Douglas's pouch, and had been extruded through the anus, pushing the anterior wall of the rectum before it. It had been successfully removed by operation.

Vesical Calculi.—Mr. W. A. STOCKS also showed thirty-seven calculi which had been removed from the bladder of a man by lateral lithotomy. Each original calculus contained a minute millet-seed nucleus, around which had been deposited some buff-coloured urates, showing a distinct concentric arrangement, and having four or five lines of a much lighter colour radiating from the centre to the circumference, after the manner of those seen in the transverse section of an orange, each stone being about three-eighths of an inch in diameter. At this stage of their development many of these stones seemed to have undergone spontaneous division through the lines above mentioned, forming a second series of nuclei. Every stone had been covered with a thick layer of phosphates, those of the primary series forming stones three-quarters of an inch, and those of the latter series, stones of about half an inch in diameter, irregular in shape and furnished with a varying number of facets.

Mammary Tumours.—Dr. W. THORBURN exhibited a series of sections of various breast tumours. He demonstrated the varieties of cancer and their modes of growth, and showed preparations illustrating every stage in the development of cysts and intra-cystic growths in non-cancerous tumours. Among the rarer forms he showed a pure myxoma, an adenoma without overgrowth of the connective tissue elements, and a typical "villous cancer."

Intra-ocular Growths.—Dr. HILL GRIFFITH showed twelve glycerine jelly preparations demonstrative of intra-ocular growths and cyclitis, and mentioned the diagnostic appearances of sarcoma of the choroid, glioma of the retina, and plastic cyclitis on the so-called pseudo-glioma.

Changes in the Spinal Cord and Peripheral Nerves after Amputation.—Dr. E. S. REYNOLDS made some observations on the changes in the nervous system after the amputation

Digitized by Google

of limbs, showing a series of specimens from a case. Having briefly referred to the history of the subject, and especially to some recent observations made by Friedländer and Krause, he pointed out that the changes in the case which he had investigated consisted in a simple atrophy of the majority of the fibres in the nerve trunk of the amputated leg, with increase of lymph spaces and connective tissue, and that this change could be traced up to the cord, principally in the posterior nerve root, but also in the anterior nerve root. In the cord the changes were limited to the lumbar region, and consisted of a slight decrease of the posterior horns and columns, and a more marked decrease of the anterior horns, affecting the number and structure of the cells in all the groups, but especially in the postero-lateral and central groups. Clarke's column was not affected.

MIDLAND MEDICAL SOCIETY.

A MEETING of this Society was held on March 2nd, Mr. Lloyd Owen, F.R.C.S.I., President, in the chair.

Locomotor Ataxia with Joint Disease.—Dr. SUCKLING showed a man aged forty-eight, who was suffering from locomotor ataxia with disease of his knee-joints. He was quite well up to twelve months ago, when he had attacks of vomiting with shooting pains in the legs. Soon after he complained of having girdle pains. The knee-joints began to enlarge about nine months ago, there being pain only in the left one. At the present time there is marked crackling on movement of each joint, with enlargement especially of the internal condyle of the femur on both sides, and partial dislocation outwards of the patella and tibia on the left side, on which side there is also some genu valgum; there is no excess of fluid in either joint. The knee-jerk is lost on both sides, the pupils are unequal and respond to accommodation, but not to light.

Tumour of Bladder treated by Supra-pubic Cystotomy.—Mr. BENNETT MAY reported this case, and showed the parts removed after death, which took place six months after the operation. In comparing the two methods of operating—viz., by the median perineal and by supra-pubic cystotomy,—Mr. May observed that the former was undoubtedly the simpler and possibly safer operation, and was an excellent means of exploring the bladder, whilst it was also quite adequate for the removal of some tumours. For the majority of cases of tumour of the bladder, however, it was far inferior to the supra-pubic operation, which gave opportunity for inspection and more thorough manipulation within the bladder. From the point of view, also, of the patient's subsequent condition, and for the purposes of permanent opening for micturition, when, as so often happens, the tumour cannot be removed, the supra-pubic operation was infinitely preferable. He had found the perineal operation a complete failure in relieving the patient's sufferings for any length of time; and for all cases of diagnosed tumour he should operate by the supra-pubic method, provided of course that the bladder could hold sufficient water.

Periosteal Sarcoma.—Mr. JORDAN LLOYD showed a girl aged eighteen who had developed a large malignant tumour of the forearm, probably a periosteal round-celled sarcoma of the ulna, with large ascending growths in the upper arm, the axilla, and the subclavian triangle. The tumour in the forearm was the first to appear, only fourteen weeks ago. This was cut into for the purposes of diagnosis, and on microscopic examination was found to be a small round-celled sarcoma. There was no history of malignancy or of injury. At the time of first seeing the case the disease had progressed too far to admit of removal.

Injury to Shoulder.—Mr. A. F. CLAY showed a man aged seventy-seven who had fallen downstairs on this shoulder; he was told by his medical attendant that he had "broken his arm high up." Three weeks after this Mr. Clay saw him, and found his humerus and clavicle intact, but about an inch and a half above the lowest part of the anterior boundary of the axilla a round hard prominence the size of a marble was seen and easily felt. It was then slightly movable, but more in the lateral than vertical direction. It followed the movements of the humerus. Since then it has become absolutely immovable and is smaller. The coracoid process on the injured side was not so prominent as its fellow.

Reviews and Notices of Books.

Lehrbuch der Chirurgischen Krankheiten des Ohres (Text-book of the Surgical Diseases of the Ear). By Prof. Dr. HERMANN SCHWARTZE. Stuttgart: Ferdinand Enke. 1885.

PROFESSOR SCHWARTZE'S text-book of aural surgery deserves the attention of all otologists, not only as coming from such a well-known writer, but also from the intrinsic value of the work. To the practitioner who is versed in otological subjects the book will derive its chief attraction from the parts devoted to the newer operations on the hearing organ, in which the author, besides collating the most recent views of others, gives his own extensive experience. A few of these may be briefly noticed.

Division of the tensor tympani is, he says, a procedure devoid of all practical value when employed for the relief of deafness, tinnitus, or giddiness. He has never seen it give any permanent relief to these symptoms, and cases are recorded in which it has provoked an aggravation of the same. As a preliminary operation in excision of the hammer it is more likely to come into use.

Excision of the drumhead and ossicles forms the subject of a very interesting chapter. Schwartze's first attempts at excising the drumhead and extraction of the entire malleus in sclerosis date from the year 1873; these failed regularly, owing to rapid regeneration of the membrana tympani. A method of preventing this regeneration was, however, devised by Kessel, which is adopted by the author. Schwartze's method of operating is as follows: The membrane is divided close to its periphery, the "tendinous ring" being also removed at the back part, according to Kessel's plan. The tendon of the tensor tympani and the joint between the stapes and incus are then divided. The membrane, together with the malleus and incus, is now grasped with a Wilde's snare and removed by a few careful to-and-fro movements. The chorda tympani is necessarily stretched, but if it should be torn across the loss of taste occasioned is usually only temporary. The cases in which the operation is recommended are mainly of two kinds: (1) Chronic suppuration of the middle ear, with caries of the ossicles, and cases of cholesteatoma of the tympanum; (2) Immobility of the malleus, caused either by total calcification of the membrana tympani or by ankylosis of the malleo-incudal joint, it having been previously carefully ascertained that the labyrinth is unaffected, and (by exploratory puncture of the drumhead, &c.) that the stapes is movable. Six cases briefly described by the author show the practicability of the operation, and that in some cases it is capable of relieving the tinnitus; the improvement in the hearing power gained, however, was not marked. On the whole, the results of excision are more favourable in suppurative cases or when there has been previous suppuration, than in cases of sclerosis.

We have dwelt at some length on this operation on account of its novelty, but there are many other parts of the book which deserve mention, notably the chapter on disease of the mastoid, a subject with which the author's name is inseparably connected. Without agreeing with all Professor Schwartze's statements, it may be said that the whole volume is replete with interest to the student and practitioner of aural surgery, and forms a valuable work of reference. It is liberally illustrated; some of the figures we recognise as coming from the author's "Pathological Anatomy of the Ear."

Diseases and their Commencement. Lectures to Trained Nurses. By DONALD HOOD, M.D. London: J. and A. Churchill.

DR. HOOD has in this small but useful work brought under the notice of nurses the fundamental facts connected with the causes, prevention, pathology, symptoms, and nursing treatment of a variety of diseases. The five

Digitized by Google

lectures of which it is composed are expressed in a simple and graphic style, which renders them as interesting as they are instructive. Lecture I. deals with general physiological considerations, and impresses the paramount necessity of cleanliness and ventilation. In Lectures II. and III. inflammation in various situations is clearly though shortly discussed. Fever forms the theme of Lecture IV., while Lecture V. is devoted to the study of certain prominent symptoms, not so much with a view to diagnosis as in order to show that different causes may lead to the same condition, and to teach the unwisdom of too ready interference. Such practical matters as poulticing, disinfection, diet in typhoid fever, ventilation, &c., are treated in a judicious and careful manner. In speaking of temperatures, we observe that Dr. Hood places the normal heat of the body at 98·2°. Though not a great matter, it would be well if this figure were changed to 98·4°, the standard generally accepted. The book as a whole is likely to prove helpful to nurses by increasing their knowledge of the reason and purpose of their duties.

A Junior Course of Practical Zoology. By A. MILNES MARSHALL, assisted by C. HERBERT HURST. Pp. 440. London: Smith, Elder, and Co. 1887.

ALTHOUGH this handbook is entitled "A Junior Course of Practical Zoology," it is one that might with advantage be worked over by many men who consider that they possess something more than a rudimentary knowledge of biology. As the author observes, a student who works conscientiously through this book will acquire a good insight into the leading facts of animal structure and a technical knowledge of the principal methods of research. The book is divided into chapters, each of which gives the characters of a representative of one of the typical groups of the animal kingdom. Thus, we have the amœba, the hydra, the liver-fluke of the sheep, the leech, the earthworm, the freshwater mussel, the edible snail, the crayfish, the cockroach, the lancelet, the dogfish, the rabbit, and the fowl. In each case the several parts of the animal are described just as it might be by an intelligent teacher who, with knife or scissors and forceps in hand, was demonstrating the parts to a class. The descriptions seem to us to leave nothing to be desired. Mr. Marshall has had large experience in teaching, and avoids the mistake of being too prolix with young students. A few illustrations are given, but are not intended to supersede the sketches that should be made by the dissector. Directions are given in regard to the mode in which the dissection should be pursued. We venture to think that in our large public schools one afternoon in the week might be surrendered to natural science, and that those who exhibit a taste for zoology should be encouraged to hunt for specimens of the animals here described, and to dissect them with the book before them. It would be, we suspect, the most popular afternoon in the week, and would be a welcome change from the dry routine of Latin and Greek as at present taught.

New Inventions.

SEWER-AIR DESTRUCTOR.

MR. G. R. KEELING has sent us an account of an invention for destroying the air from sewers, and for promoting in them at the same time a current which would ensure their ventilation. The apparatus is a column to be placed over the sewer, and which could be used as a lamp standard; within it is situated a large gas-burner, which not only induces an upward current, but is said to consume all the air which passes through it. Mr. Keeling claims that some thousands of cubic feet of noxious gases can thus be extracted hourly from any sewer, and fresh air drawn into it. The amount of gas which is consumed is not, however, mentioned; but, if this be not great, it is likely that his invention will be of practical value.

AN IMPROVED CATGUT-HOLDER.

MESSRS. JOSEPH WOOD & Co., of York, have submitted to us an improved catgut-holder, which has certain excellent features. A reel of prepared catgut is enclosed in a glass vessel of oil, which is securely sealed at the top. One end of the catgut is brought out through a very small hole in the centre of the sealed top, but the aperture is so arranged that no oil leaks out, and there is no tendency for the end of the catgut to slip back into the bottle. By this means the catgut is well preserved, and as much as is required can very easily be at any time removed. The bottle seems to answer its purpose well.

LAPAROTOMY FOR GLUTEAL AND SCIATIC ANEURYSMS.

THE treatment of gluteal and sciatic aneurysms is attended with many difficulties, and cannot be considered as satisfactory. Dr. F. S. Dennis of New York has recently published a paper containing reports of three cases of the kind, which were treated by laparotomy and ligature of the internal iliac artery in the pelvis. The ligature of the internal iliac artery has been attended with a high rate of mortality—70 per cent.,—the causes of death being secondary hæmorrhage, uræmia, and various septic inflammations. In some cases the operation has been attended with very considerable difficulty. Dr. Dennis proposes to obviate these dangers by opening the abdominal cavity in the middle line, turning out the omentum and small intestines, and then, having clearly defined the artery, to divide the peritoneum over it and pass a ligature: the whole being conducted with stringent antiseptic precautions. He has himself practised this treatment in two instances. The first case was one of double gluteal aneurysm in a woman sixty years of age; both internal iliac arteries were tied; the patient died on the fourth day from suppression of urine. His second case was in the person of a girl eighteen years of age with what appears to have been aneurysmal varix of the left buttock, the evidence given in the paper not showing that there was any aneurysm proper; the internal iliac artery was tied, and the patient made a good recovery, the only complication being albuminuria for the first two days. A third case in which the same operation was performed is related by Dr. Dennis; it occurred in the practice of Dr. Locke Chew, in the person of a negro forty-six years of age, in whom a spontaneous gluteal aneurysm developed; the internal iliac artery was tied, and the patient made a good recovery. There are three quite distinct points which must be kept separate in estimating the value of Dr. Dennis's suggestion, which has the support of at least two admirable cases. The first of these is the propriety of ligaturing the internal iliac artery for gluteal and sciatic aneurysms; of this there seems no room for doubt, the Hunterian operation offers a better prospect of cure than any other known means. The second is the value of antiseptic surgery in this operation; the almost entire freedom from suppuration obtained in these three cases is the result of that, and not of the mode of operating, and there can be no doubt that the operation performed without opening the peritoneal cavity would give very different results in the hands of careful antiseptic surgeons from those hitherto obtained. The third point is the most convenient and best way of reaching the artery. Three ways at least suggest themselves—the old retro-peritoneal operation, laparotomy without removal of the intestines, and laparotomy with removal of the intestines. Dr. Dennis is very emphatic that "laparotomy in no way increases the danger of the operation, and that it is of very great advantage to remove the intestines from the abdominal cavity, as this gives the operator an easy access to the artery." On both these points there is room for difference of opinion, and we must await further experience before a definite opinion can be expressed. In any case Dr. Dennis's paper is a valuable contribution to surgery. We could have wished for fuller details than are given in the report, especially with regard to the condition of Dr. Dennis's second case, the account of the symptoms of which is meagre.

THE LANCET.

LONDON: SATURDAY, MARCH 26, 1887.

THE breach between the conjoined Colleges and the Society of Apothecaries continues to widen. In spite of numerous efforts to adjust the differences between these bodies, there is no diminution in the obdurate resistance with which the very reasonable desires of the Society have hitherto been met. The late resolution of the General Medical Council earnestly advising the Colleges to reconsider their position and come to an agreement has, notwithstanding the zealous support of the direct representatives of the great body of medical practitioners, effected nothing in the way of reconciliation. On the contrary, it has, like every other effort in the same direction, served only to strengthen the resistance opposed by the Councils of the Colleges to any arrangement with the Society of Apothecaries. Though stated in terms of studied moderation, while at the same time clearly expressing the wish of the General Medical Council, the request has met with an unqualified refusal. We shall, therefore, in all likelihood find ourselves involved, perhaps more deeply than ever, in those very difficulties which it is the object of the Conjoint Scheme to remove. The Colleges and the Hall will henceforth be driven to compete with one another. A diploma, one of the far too numerous minor medical qualifications, will be invested with increased powers, and, for anything we can see, with increased popularity. Such a result, as is now sufficiently well known, is viewed with lively and natural apprehension by the great body of alumni of both Colleges. They foresee that the contest is fraught with possibilities of evil for the contemplated new London degree. The latter must in any case hold its own with the similar qualifications of existing universities, and it should by all means be spared the opposition of the remodelled diploma of the Apothecaries. It is somewhat difficult to ascertain the individual opinions of the members of the Comitia of the Royal College of Physicians on account of the secrecy which attends their deliberations. A greater degree of publicity would probably better subserve the interests both of the public and the College. We have reason to believe, however, that some of the Fellows do not even admit the probability of competition between the conjoint qualification and the licence of the Society. In their eyes the former is a thing by itself; it has no relation to any other diploma, consequently any suggestion of rivalry between it and the licence is out of the question. To reason thus may be logical after a fashion, but it is not practical. Whatever the authorities of the College may think, an actual competition between the two qualifications must be one result of their short-sighted and ill-advised policy—a result the significance of which cannot be ignored. The Society is determined to exert its right of appeal in order to obtain the requisite powers of examination in surgery. There is little, indeed no, doubt that those powers will be granted, and there is an absolute certainty that the influence of competition thus awakened will tell seriously against the work of the Colleges themselves, without in any way adding to the public good. As regards the general population, indeed, the prospect rather is that the exclusion of the Apothecaries' Society may become a disadvantage, which would be avoided by the adoption of an opposite course. When the powers applied for by the Society have been acquired, and a new class of practitioners (capable as regards the fulfilment of every legal condition, but with an admittedly lower qualification) is annually sent forth into professional life, we shall understand how sorely the cause of medical education has been wounded in the house of its friends, and practitioners will note how little their interests are considered by the Colleges of Physicians and Surgeons. The alternative policy should have been by no means difficult of adoption. All that is asked for on behalf of the Society of Apothecaries is the privilege of examination in certain subjects—botany, pharmacy, and chemistry—which it may fairly claim as natural to its province. The demand is a very moderate one. Its refusal is most unwise as well as illiberal, and we doubt much if the medical world in years to come, when it has to deal with the hydra of multiple qualifications, will readily forgive those who in our time are carelessly tossing aside the golden opportunity of curtailing that evil, at least in London. It is exceedingly doubtful whether the same question which is pressing for solution in Ireland will be settled otherwise than it is likely to be in London. In the interest of medical education and practice we hope for it a happier fate.

BY degrees London is being cleansed of its sores; the worst areas are being gradually cleared, and are being replaced by dwellings which, if not wholly free from objection, are a very distinct advance upon those which they replace. In no district of London has greater or better use been made of the legislation which dates from the year 1875 than in St. Giles's, where, thanks to the efforts of an able officer of health and a public-spirited vestry, changes have been brought about which have raised one of the most insanitary districts of the metropolis to a position which is very different from that it formerly occupied among other metropolitan parishes. The work of improvement has not been done without cost to the metropolis, but London will gladly bear the expense which has been incurred, for its prosperity is largely dependent upon the health of its inhabitants. London, however, is now represented by the Metropolitan Board of Works, and it is no secret that this Board does not regard with unmixed satisfaction the expenditure of large sums of money upon the removal of conditions which are prejudicial to health. Improvements of main thoroughfares, which all the world can see and admire, are more readily undertaken than those of some hidden area, which are, as a rule, known only to its own denizens and the few officials whose duties require them to be intimately acquainted with its evils.

Of this tendency there has been recent example. The Shelton-street area was reported by Mr. S. E. LOVETT, Medical Officer of Health of St. Giles's, to the Metropolitan Board of Works in 1883, under the Artisans and Labourers' Dwellings Improvement Act, 1875, but it was not until some nine months later that a Committee of this Board visited

Digitized by Google

the spot, and then only with the result that they declined to prepare a scheme for its improvement; but the St. Giles's Board persevered with their intentions, and communicated to the Home Secretary a copy of the medical officer's report. In the beginning of 1885 an inquiry was held by order of the Home Secretary into the correctness of the report, and subsequently Lord CROSS himself inspected the site. The outcome of these proceedings was that the Metropolitan Board of Works were required to prepare a scheme, and the official inquiry which was held in consequence terminated last Saturday.

The nature of this investigation was such as to sadly perplex anyone not conversant with English procedure. The Commissioner, Mr. CUBITT NICHOLS, who was appointed by the Home Secretary to conduct the inquiry, was himself the official who had advised the necessity for the Metropolitan Board to prepare the scheme, and the authority whose duty it was to adduce evidence on behalf of its confirmation was the very Board which had previously declined to move in the matter. Notwithstanding these anomalies, the necessary facts were elicited, and no doubt can exist in the mind of anyone who heard the evidence, or who had inspected the site, of the urgent need for its improvement. The condition of the houses, the absence of sufficient back space, the impossibility of their ventilation, as well as their faulty arrangement, make it no matter for surprise that disease was rife among the inhabitants. In the four years from 1882 to 1885 the death-rates had ranged from 32·5 to 51·9 per 1000 of population, and an analysis of death-rates led to the same conclusion—that the area was unhealthy in a high degree, and that nothing short of its complete clearance would afford an effectual remedy.

The scheme which the Metropolitan Board have submitted for approval is by no means the best that could be designed. The desire to minimise the cost of the undertaking has, we believe, led them to hinder for many years to come the full changes which are distinctly needed. It is within the province of the Home Secretary to improve the plan proposed, and we trust he will do so with no illiberal hand. The enormous expense to which London is put through outbreaks of infectious disease is perhaps no concern of the Metropolitan Board, but is of vast importance to the ratepayers. To the steps already taken by Mr. LOVETT and the St. Giles's Board of Works is greatly due the freedom from typhus fever which London now enjoys. In past years St. Giles's was again and again the centre from which this disease spread to other parts of the metropolis, and the money spent in improvements of the district has already made ample return in leading to the disappearance of this serious cause of mortality. But this is not all. It must not be forgotten that high rates of general mortality are accompanied by high rates of sickness, and that sickness amongst the poor is attended by increased expenditure in poor relief. The interests of the ratepayers are, therefore, best consulted by the removal of those causes which tend to produce ill-health and its companion, poverty.

It may be hoped that this long-delayed improvement will be speedily carried into effect, and that no desire to lessen its cost will prevent the scheme being made in every sense of the word complete. There is no better investment of public money than that of purchasing health for the inhabitants of this crowded city, and the Metropolitan Board of Works may reckon upon the approval of the more thoughtful of the London taxpayers, if they utilise in the best way the powers with which they are endowed.

SIR RUTHERFORD ALCOCK, in another letter to *The Times*, returns to the subject of the impecuniosity of the London hospitals. This vast metropolis, with its unequalled wealth, its assessable property of £25,363,550, and its ever-increasing luxury, cannot, or rather does not, support its 150 charitable institutions for the treatment and comfort of the sick poor. None of them have yet actually closed their doors, but many have closed some of their wards. The supply of beds is seriously curtailed, and all these institutions are being carried on with a wholly inadequate support and are in a state of chronic insolvency. The great majority of the inhabitants do not subscribe at all—only 100,000 out of 4,000,000, or 2½ per cent. Sir RUTHERFORD ALCOCK does little more than repeat himself and his thesis. He takes occasion to show how unhelpful the critics of his first letter have been. Mr. BURDETT'S evidence that more is raised now than before the establishment of Hospital Sunday does not alter the fact that what is raised is still wholly inadequate and utterly unworthy of the wealth and the charity of London. Mr. BOUSFIELD'S lament of the unsuccess of the provident dispensaries is to little more purpose; and his complaint that Sir RUTHERFORD ALCOCK has too exclusively advocated the collection of unlimited funds for the maintenance of the present unorganised competition of medical charities is sufficiently met by SIR RUTHERFORD'S suggestion in his former letter that a Royal Commission should be appointed to inquire, amongst other things, if any better administration of hospitals can be devised. Sir RUTHERFORD ALCOCK will be readily acquitted of any want of sympathy with wise attempts to organise charity. He is notoriously one of the leading spirits in the Metropolitan Society for the Organisation of Charity. But his perception of the enormous need for hospital beds in a population of over 4,000,000 of people and sense of the depressing inadequacy of the support forthcoming fills his mind, and he is fain to confine himself to this one complaint until it be realised and felt by all classes, the working and the wealthy alike.

Sir RUTHERFORD ALCOCK is not without hope in connexion with the Jubilee. Her Majesty's intention is to devote a considerable amount of what is raised to some charitable object of adequate scope; he thinks the London hospitals in their present distress may well commend themselves to the ever-ready sympathy and consideration of the QUEEN. The London hospitals can only hope to benefit, of course, by money raised in London. But, as we have urged from week to week, no cause can compare with theirs in strength of claim. If this resource should fail and no substantial help should come out of the City parochial charities, nothing remains but a hospital rate, which would, with many objections, have this recommendation that it would make all contribute according to their means to this great object. Still, we trust, for the credit of old English charity, that it will not come to this. Hospitals supported by rates and administered by ratepayers would be very different things from the institutions of which we are all proud. They would be claimed, as of right, by those who

Digitized by Google

used them, and by many whose cases were not fit, and all that personal kindness and gratuitous service which we associate with the provision and administration of hospitals in England, would be replaced by paid labour and officialism. They would differ but little from workhouse infirmaries. If this dismal change is to be averted, liberal gifts will have to be made, and made soon. Millionaires could remove the debt of every hospital in London, and leave to their less plethoric fellow-citizens the duty of endowing each approved hospital with a sum that, with current subscriptions, would restore the equilibrium of the finances and the peace of anxious committees. But no time is to be lost. A few leading citizens, a few leading physicians and surgeons, and the treasurers of the great hospitals in co-operation, might even now place this cause in the very front of those events that will make the Jubilee of Queen VICTORIA memorable in all after-time.

PROFESSOR ROMANES made the "Mental Differences between Men and Women" the topic of a lecture recently delivered at the Royal Institution. The views his remarks disclosed are those which must, we fancy, be entertained by every well-informed and unprejudiced observer. Mental differences do exist between men and women, which are not simply the differences between individuals of the two sexes, but of a nature to show that they depend upon the diverse characteristics and purposes of the two classes of organic development. And these differences, when they come to be studied closely, will be found to partake very much of the nature indicated by Professor ROMANES when he hinted that women are gifted with a more acute and facile power of acquisition than men, while they are less able to originate ideas, and therefore not so well qualified to take the lead in intellectual work. Professor ROMANES alluded to the somewhat smaller average weight of the brain in women than in men, the difference being about 5½ oz. The average male encephalon has been said to weigh 49½ oz., while the female average weight has been put at 44 oz. There are, however, very great variations. Of 278 male and 191 female brains, the smallest male weighed 34 oz., while the largest weighed 65 oz. The male encephalon in 170 cases out of the 278 ranged from 46 oz. to 53 oz. The smallest female brain of the total 191 weighed 31 oz., and the largest 56 oz.—that is, 9 oz. less than the weight of the largest male brain. Of 125 brains selected from the 191 female brains, the weight ranged from 41 oz. to 47 oz. So that we may say the average male encephalon weighs from 46 oz. to 53 oz., while the female weighs from 41 oz. to 47 oz. Thus, speaking broadly, it is correct to affirm that the male brain is heavier than the female, and those who, perhaps too hastily, measure the mind by the absolute brain-weight, infer that in its totality the mind of man must be greater than the mind of woman. This, however, leads us to make a remark which we do not remember to have encountered—namely, that as there is very little difference between the proportionate weight of the cerebellum to the cerebrum in the two sexes, the proportion being as 1 to 8¼ in the male and as 1 to 8¼ in the female, there scarcely seems ground to infer from the existence of a smaller brain in woman than in man that she is necessarily inferior in proportional mental powers because it cannot be forgotten that woma average a much smaller organism than man. so far as we are aware, been proved, or eve contended, that a small man with a proportio sized though actually small brain is not intellec good as a larger man with a brain only propor greater in size. We know that it has been the p. to weigh brains without reference to the total w of the bodies with which they were associated, but has always struck us as an unfair proceeding. It wou we believe, have been found to explain most of the di crepancies between actual mind-power and brain-weight which have done violence to the prejudices of those who weighed the understanding solely by the brain, to take into consideration the weight of the whole body. In short, we venture to urge that it is not, in our present state of knowledge at least, a justifiable proceeding to measure the mind by the brain without taking into account the organism of which the brain forms part. It may well be that a small brain in a small body may be equally effective as a mind-organ as a larger brain in a larger body; and it follows that too much importance may be attached to the fact that the average weight of the female brain is less than the average weight of the male brain, because the average weight of the female body as a whole, including the brain, is less than that of the male organism, and it has not yet been shown that the female brain is smaller *proportionally* than the male. We think "the mental differences between men and women" are rather differences of kind than of degree, and this will accord with the inferences of Professor ROMANES, though it may not so closely accord with the facts by which he seeks to support them. There are great differences in mental power and capacity between men and women, and we believe they are of a nature to render impracticable the levelling views and purposes of the promoters of uniformity, but it is not upon such coarse data as those of relative weight that the differentiation of mental power as exhibited by the two sexes can be satisfactorily established or elucidated.

THE nature and mode of action of the poisons of venomous serpents have always attracted considerable attention. The effects of snake-bite are so striking in their rapidity and severity as to stand in great measure apart from other animal poisons. Much was learnt of their constitution by the researches conducted by Drs. FAYRER and BRUNTON in 1872–75, and still more has been added to our knowledge in a monograph by Dr. WEIR MITCHELL and Dr. REICHERT, recently published by the Smithsonian Institute. These researches, although limited to a comparatively few species of snakes, including, however, the most venomous, bear out the view long since advanced by the first named, that snake venom is not simple, but that it contains one or more poisonous substances. In the first place, it must be acknowledged that the poisons are of chemical nature, and not vital or the product of vital action. They do not fall, then, into the class of ptomaines or other alkaloids which are the result of organised vital activity; for although micrococci are described in the fresh venom capable of multiplication, no support is gained to the idea that they have anything at all to do with the

Digitized by Google

the spot, and ' The venom is, however, found to yield prepare a sc[illegible]ers which are held in solution, and can be Board pers[illegible]y dialysis into coagulable proteids or globulins, to the Ho[illegible]agulable proteids or peptones. In some venoms In the [illegible]lins are further capable of subdivision according the Ho reaction, but in cobra venom there is only one subse[illegible]n, and a peptone which differs from others in being outc[illegible]lated by prolonged boiling and not being precipitated Bo[illegible]nercuric chloride and absolute alcohol.

th[illegible]Drs. WEIR MITCHELL and REICHERT have submitted to a [illegible]ost careful physiological analysis these different products of snake-poison, and their interesting conclusions deserve to be widely known. The venoms resemble closely the salivary secretions of other vertebrates; and their active principle, which can be maintained in the dried state or in such preserving fluids as glycerine and alcohol, is contained in the fluid part of the venom only. This active principle is divisible, probably in all cases, into two classes of proteids—globulins and peptones—of which the former may consist of several distinct principles. If taken into the stomach during the intervals of digestion the poisons may prove fatal, provided that they contain a sufficient quantity of dialysable peptone, whereas during digestion they are rendered harmless. The chief local antidotes are permanganate of potash, ferric chloride, and tincture of iodine. The venom has a powerful local effect upon the living tissues, inducing more rapid necrotic changes than any other known organic substance. It renders the blood incapable of coagulation, and exerts a local effect on the capillaries, so that extravasation occurs from the vessel walls being unable to resist the normal blood-pressure, those capillaries yielding most which are nearest to the larger bloodvessels, and ligature of vessels lessening the amount of extravasation. The altered condition of the corpuscles, which become soft and spherical and tend to fuse together, is a further aid to the escape of blood into the tissues. Sometimes this extravasation occurs into the substance of organs—as the brain, kidneys, or heart. The effect of the venoms was also carefully noted upon the respiratory and nervous systems and on blood-pressure. They show that changes in the pulse rate following administration of the venom depend upon two antagonistic factors: the one, which excites the accelerator centre, tending to increase the rate; the other, which acts directly upon the heart, tending to diminish it. The variations noted in the arterial pressure were attributable in the main to three causes—viz., depression of the vasomotor centre, depression of the heart, and capillary obstruction. The respirations are primarily increased, and secondarily diminished in frequency; these being again due to the operation of two antagonistic factors—the one an irritation of the periphery of the vagus, the other a depression of the respiratory centre. Death may occur through the paralysis of the respiratory centres, or cardiac paralysis, or hæmorrhages in the medulla, or from the widespread destruction of the red corpuscles. The research clearly proves that the antagonistic and varying physiological effects depend upon the admixture of the separate principles—the globulins and peptones; and comparative study shows that the globulins are the chief agents in the blood-destruction, and in producing changes in the capillary walls; whilst they also act more upon the accelerator centres of the heart, and are therefore responsible for the increase in pulse rate; and, further, they are the chief cardiac depressants and paralysers of the respiratory centres.' In some respects, then, the globulins must be considered as more toxic than the peptones, which, although active in producing œdema and necrosis of tissue, have little power in preventing coagulation or in altering the corpuscles and capillaries; moreover, these constituents act on the blood-pressure, and are the chief factors in increasing the respiration rate by acting on the periphery of the vagi nerves.

The great merit of this research is the demonstration of these distinctions in the constituent poisonous principles, pointing to the differences in the action of different kinds of snake-bite, being explained by the relative predominance of one or other of the constituents. Thus in crotalus venom there is a much greater proportion of globulins than in the cobra venom, which may explain the marked local destructive effects of the former as compared with that of the latter; but the peptone of cobra venom would seem to be more active in proportion than that of the crotalus. The conclusion that, owing to their proteid nature and close relation in composition to the blood, it is almost futile to seek for a chemical antidote—for what would destroy the poison would have a similar action on the blood itself,—is, in spite of its hopelessness, unfortunately in accord with experience. What is required, and what should be sought for, is a physiological antagonist rather than a chemical antidote, and in this direction we may look for research to tend in the future.

THE report of the last Council meeting of the Royal College of Surgeons was unusually interesting from more than one standpoint. In the first place the Council have decided to rescind their former resolution to grant the Fellowship to members of fifteen years' standing without an examination in anatomy and physiology. We have more than once pointed out that such a method of bestowing the Fellowship would tend to deprive this diploma of some of its present academic status; we therefore gladly welcome the determination of the Council not to persevere in this course. The Council offer as their reason for rescinding the resolution the difficulties involved in giving effect to the resolution in the new Charter about to be applied for. Surely this is a very weak and paltry excuse. There could be no difficulty in inserting a clause in the Charter in the sense of the resolution, if the Council chose to do so. A far better reason, we think, exists in the incongruity of instituting a high-class diploma in surgery to promote the science and art of surgery, and then in giving this diploma away wholesale without adequate test examinations, merely for the purpose of increasing the number of Fellows, which was the avowed object of the Council in proposing changes in the existing conditions.

While congratulating the Council on their present change of tactics, we cannot resist the suspicion that the real cause for this rescission lies in the absence of any clear and well-defined policy on the part of the Council, and in their having acted hurriedly. These questions were not well weighed; they were not discussed as part and parcel of a general policy, nor were they submitted to the Fellows and Members previously to being formally and finally discussed in the

Digitized by Google

Council. The proposed change was just one of those which could advantageously have been submitted for discussion. Would the Members care for a Fellowship diploma on those grounds? Would Fellows approve of an extended Fellows' list with the avowed object of simply increasing their number? Thus the Council is in the rather undignified position of rescinding a resolution—that is to say, of undoing at one meeting what they had done at a former one. On the other hand, the Members have already publicly declared their unwillingness to accept the Fellows' diploma on the terms offered. This rescinding reminds us of the memorable statement made by the then President at the general meeting of the Fellows and Members in 1884, about Resolutions of the Council which were binding and others which were not binding; and of more recent occasions—as for instance, when the Council decided not to accede to the recommendation of the Association of Fellows to create Honorary Fellows, and then within a few months changed their minds and decided that they would create a new class of Honorary Fellows.

The memorial from teachers in surgery concerning the proposed disposal of the ERASMUS WILSON legacy was referred to the Committee on the Extension of the College Premises. It is to be hoped that this Committee will give way in part on such a question as this. We believe that but a very small minority of the Council are at all strongly in favour of enlarging the present museums. The days of putting up mere "pickles" are past and gone. The interest of museum specimens lies not in their size so much as in a careful examination into their minute structure, their intimate nature, and mode of growth. For such studies as these laboratories are needed rather than more shelf-room for unstudied, and often unintelligible, crude specimens. The College of Surgeons' Museum is at present too much composed of bottle preparations. To spend this legacy in increasing these museum specimens is a waste of money, not justifiable while London, of all capitals in the world, is the only one in which adequate laboratories for scientific work are still unknown and non-existent. We can only hope that the Council of the College of Surgeons will not neglect this chance of helping to put London on an equality with Edinburgh and with foreign capitals in teaching capacity, and of filling a hiatus in the teaching apparatus which is of vital importance to its completeness.

Annotations.

"Ne quid nimis."

DEGREES FOR LONDON MEDICAL STUDENTS.

THE communications laid before the Fellows of the Royal College of Physicians of London, which are referred to in another page, presage a stormy career for the Charter now being drawn up by the two English Colleges conjointly. The Irish Colleges plainly say that they intend to ask for like privileges, and the Scotch Colleges intimate that, contrary to their desires, but as a necessary measure of self-defence, they will be obliged to take a similar step. The University College of Bristol appeals against a residential qualification being included in the terms on which a degree is to be granted, whilst King's and University Colleges have made a formal joint application to be included in the movement, and furnish the Arts and Science Faculties, leaving that in Medicine under the control and management of the two Royal Colleges. The letters from the Bristol College and from King's and University Colleges were referred to the Committee of Delegates, whose next meeting will be held shortly. The two most difficult points in the scheme will then be before them for consideration. Shall residence be a *sine quâ non*, and, if so, for how long a period? Shall the Colleges ask for a purely professional degree, or will they co-operate in forming, and take the initial step in creating, a new and a real University in London? It is difficult to understand the position of the Colleges, in putting into the foreground of their claim the advantages and superiority of clinical teaching and clinical opportunities in London, if some residential period is not insisted on, and this might be for the twelve months preceding the examination for the M.D. degree. We see no reason whatever why every candidate should not be compelled to attend definite courses in clinical subjects in London in order to obtain a London degree, which would be quite a special honour, and differ *in toto* from the mere qualifying titles granted by the Conjoint Examining Board in England. It is evidently clear that University and King's Colleges will go to the Government for a Charter to grant *non*-medical degrees, and that the Councils of those bodies would rather assist the Royal Colleges than be in opposition to them, and we hope that a conference may be held so as to allow a joint action to be pursued. The feeling against a purely professional degree is very strong in medical as well as in outside circles, whereas everyone acquainted with the higher education in London recognises the need for a real Teaching University, of which those Colleges only can constitute the non-medical factors. The opportunity for doing the work which the present University deliberately threw away is once more to the front, and we hope that the occasion for removing a grievance under which the metropolis, alone among great cities, is now suffering will be seized and promptly acted on. The Irish and Scotch Colleges are obviously animated by mere personal considerations. They cannot say for a single moment that Trinity College and the Royal University in Ireland on the one hand, or the Scotch Universities on the other, stand in a position as regards Dublin or Edinburgh students comparable with that in which the University of London places itself in reference to London teachers or London students. The latter is an imperial examining board with a mere habitation only in London; the others are local universities, and a local university is what London asks for, and against its formation no fair contention can be urged.

FEVERS AND FIRES IN BLACKPOOL.

IN his recently issued report on the health of Blackpool Dr. Henry Welch draws the serious attention of the sanitary authority to the want of preparedness on their part to deal properly with cases of infectious diseases by means of isolation. He says that for four years he has vainly endeavoured to persuade them to provide proper accommodation, that the borough is still not one whit nearer its possession, and he fears that nothing but a serious epidemic will awaken the sanitary authority to a sense of its duties in this respect. The advice thus given has been locally received in two very different fashions. The *Blackpool Times* evidently recognises in Dr. Welch the authorised local adviser in such a matter, and by supporting his views it shows that it appreciates the unflinching honesty with which the best interests of the town have been advocated by him. It goes on to remind its readers that Dr. Welch by no means stands alone in condemning the insufficiency of the existing hospital provision. Thus, it quotes Dr. Thorne Thorne, who, in his official report, describes the building as badly situated

Digitized by Google

—hidden as it is behind a cemetery,—as faulty in construction, and as so imperfect in its accommodation that the medical practitioners in the town did not feel justified, except under special circumstances, in recommending their patients to resort to it. This was in 1879, but quite recently Dr. Page, also of the Local Government Board, felt it his duty to urge upon the authority the provision of "adequate hospital accommodation for infectious diseases." But the *Blackpool Gazette* adopts a precisely opposite tone. It takes the officer of health seriously to task for the performance of his duty in this matter. It talks of "blatant alarmists"; of the prospects of the season being injured "by the professional alarmists and gadling idlers of the borough"; and, with reference to the possibility of an epidemic, it rejoices in the fact that "we haven't got an epidemic." It then goes on to seek a simile in order to enforce its retrograde views. Noting the reference which Dr. Welch has made to the possibilities of an epidemic, it proceeds to say that the next discovery that will be made will be that "if all the houses in Blackpool took fire at once, the present fire brigade would be unable to cope with the flames." How this most inappropriate simile could have been put forth will surprise all who have the most rudimentary knowledge of the subject under consideration. Neither epidemics nor fires seize upon all houses "at once." Both the medical officer of health and the superintendent of the fire brigade know that epidemics and fires have beginnings, and that in order to prevent those beginnings from becoming wide extensions, over which the authority and their officers will lose all control, it is necessary to have the means for dealing with the first signs of the evil. We can hardly conceive that Blackpool has no sufficient means for extinguishing the ordinary fires to which such a borough is subject, and which, if not checked by efficient means, would end in a widespread and disastrous conflagration; neither do we imagine that the authority are priding themselves on any such unpreparedness, because "we haven't got all the houses on fire at once." But, on the other hand, we do know that they have not the means for properly isolating at the same time the most insignificant number of two or three different infectious fevers, such as every town with a population such as that of Blackpool is always liable to, and which a seaside resort on the Lancashire coast is exceptionally likely to receive; and all that Dr. Welch and others ask for is that, on the basis of the provision made by all sensible people for the prevention of fires, adequate provision should be made for the simultaneous isolation of a few cases in both sexes of the several current infectious fevers, and this without subjecting those who quit their houses for the protection of the public health to the risk of contracting a disease other than that for which they are professedly isolated. Perhaps we shall next be told that these, too, are alarmist views, and that the absence of the needed provision has not been associated with the occurrence of any epidemic. If so, we trust that the simile of fire prevention will still be adhered to, and that the inhabitants will be advised to drop their fire insurances and to trust to some old leaky parish fire-engine, on the ground that there has for years past been no general conflagration in the borough. But, quitting this unfortunate simile, we would remind Blackpool that its credit as a health-resort demands the limited provision which is asked for. The borough is one of those which has adopted the compulsory notification of infectious diseases, and the public naturally imagine that the sanitary authority wanted to know where infection existed in order that they might take the ordinarily received means of staying its spread. As yet this has not been done in the matter of isolation provision, and we would urge that the true interests of the borough—including its financial interests—will be best served by giving heed to the advice of their medical officer of health in this respect.

THE VARIATIONS IN THE SPECIFIC GRAVITY OF THE BLOOD IN HEALTH.

MR. E. LLOYD JONES has lately been investigating this subject, and has adopted, with some modification, the principle of the plan suggested by Professor Roy to determine the specific gravity of the blood. Professor Roy simply introduced a drop of the blood to be examined, taken up by a hypodermic syringe, into a mixture of glycerine and water of known specific gravity, observing whether the blood tended to rise or sink in the solution. Mr. Jones found that a better method was to use a fine glass pipette, the point of which was bent at a right angle. When the point was brought into contact with the blood a small quantity immediately entered the tube, and the point being then introduced into a mixture of glycerine and water of known specific gravity the blood could be blown out horizontally, and its disposition to rise or fall could be instantly seen. About thirty test mixtures of definite specific gravity were used, the conclusions at which Mr. Lloyd Jones, whose paper is contained in the last part of the *Journal of Physiology* (No. 1, 1887), were as follows: The specific gravity of the blood is highest at birth, being at a minimum between the second week and the second year, and rising gradually to a point attained in the male between the ages of thirty-five and forty-five, in the female after the climacteric. Mr. Jones finds, as a rule, the specific gravity of the blood tends to be higher in the male than in the female, and that in the female the child-bearing period is marked by a fall. The specific gravity in the two sexes is probably only the same at the extremes of life. The effect of pregnancy was found to be that the specific gravity of the blood was slightly diminished, though it still remained well within healthy limits. In regard to food, the immediate effect of mixed food is to cause a fall in the specific gravity of the blood; if alcohol were taken this fall was not observed. Exercise, if gentle and not too prolonged, causes a fall in the specific gravity; if perspiration becomes well marked the specific gravity rises, as it does when violent exercise is taken. The conditions of the circulation in the affected part modify the specific gravity of the blood circulating through it. It is always high in a passively congested part. It varies also in different parts of the body. It exhibits a certain diurnal variation, tending to fall during the day and to rise at night.

LONDON WATER-SUPPLIES.

THE report of General A. de C. Scott, the metropolitan water examiner, for the month of January has been issued, and, as the author states, is compiled from information collected under instructions issued by the late water examiner, Sir Francis Bolton. The results of the analysis of the different waters supplied to London will be read with interest. The Thames water supplied by companies from this source was characterised by the large proportion of organic matter present in all cases; in the previous month this pollution was limited to the water of the Grand Junction and Southwark Companies, but in the following month the whole of the Thames-derived waters had become equally affected, samples of the two first-mentioned companies containing finely divided suspended matter, which was found on microscopic examination to contain living organisms. The water drawn from the Lea and distributed by the New River and East London Companies also showed a very marked increase in organic matter as compared with the December samples. The pollution is said to be due to the floods; however this may be, it is no great consolation to London water-drinkers. In a letter appearing in *The Times* of last week, attention is called to the pollution which "is poured into the Upper Thames by the tributary streams which discharge into its

Digitized by Google

waters the sewage of towns and villages, the filth of paper-mills and other works, and farmyard drainage." The town of Staines especially discharges all its sewage into the same river in uncomfortable proximity to the intakes of the water companies. The Thames has indeed been described as the natural outlet for sewage, and if this is to be accepted we are compelled also to regard London water-drinkers as the natural consumers of Staines sewage. The purity of London water-supplies calls loudly for improvement; the story of cholera in 1866, spread through water, has been too soon forgotten, and London possesses no organisation or administration which will enable a very definite danger to be seriously considered. It is, indeed, to be feared that some great calamity will be required to bring about a radical change in the sources of London water-supply.

EFFECT OF MASSAGE ON EXHALATION FROM THE LUNGS AND SKIN.

DR. STABROVSKI has published a series of laborious researches made with a view to determine the effect of massage upon the pulmonary and cutaneous exhalation. They were carried out in Professor Manassein's wards in St. Petersburg on fourteen persons, nine of whom were in good health and the remaining five convalescent from various acute diseases. In each case the duration of the observations was ten days, during the first five of which massage was practised. Deep kneading was practised for the first two days, after which the body was washed over with a wet sponge to remove the fatty matter adherent to the surface of the skin. During the next two days deep rubbing was practised, and then the wet sponge used again. On the fifth day deep rubbing with the dry hand was practised. The massage took place at 10 A.M., except in two cases, where it was performed at 7 P.M., with the object of observing its effect on nocturnal perspiration. The sittings were of an hour's duration. The results in the different cases were discordant. In five cases there was an increase in the pulmono-cutaneous exhalation and a diminution in the amount of urine, the increase occurring shortly after the massage, so that when this was practised in the morning the perspiration was increased during the day, but became normal during the night. Similarly the quantity of urine fell during the day and rose again at night. In three cases the massage increased the quantity of urine and diminished the pulmono-cutaneous exhalation. In the remaining six cases both the urine and the pulmono-cutaneous exhalation were increased during the period of massage. The general effect on the pulse was to lower it some ten or fifteen beats. No alteration appeared to be produced in the rate of respiration.

RAT POISONS.

AN inquest was held last week by Mr. Wyatt, the coroner for Camberwell, on the body of a young man who was found dying on his doorstep. The deceased recently lost his situation, and shortly afterwards quarrelled with the young woman to whom he was engaged. He was subsequently heard to remark that he had not a friend in the world, and that he contemplated putting an end to his existence. Dr. Power stated that he had analysed the contents of a box of rat poison found on the deceased, and discovered that it consisted of pure arsenic. There was more than enough to poison the whole street, and it could be purchased by any child at the nearest chemist or oilshop for a penny. The jury returned a verdict of "Suicide whilst in a state of unsound mind," and expressed the usual opinion that the indiscriminate sale of deadly poisons was not desirable, and that it would be as well if something could be done to put a stop to it. We have frequently pointed out that the various rat poisons and rat pastes now so extensively sold afford the public a wonderfully easy means of obtaining in unlimited quantities a selection of poisons without the inconvenience of question or inquiry of any kind. One of these preparations contains arsenic, another is composed of strychnine, whilst a third consists of arsenic, strychnine, and phosphorus combined—in fact, the choice is unlimited.

THE CHARGE AGAINST GUY'S HOSPITAL.

A MOST opportune and striking illustration of the straits to which even our great hospitals are reduced has lately happened. The public is, of course, very much shocked. But what a pity it is that the public was not shocked long since into doing more for the hospitals, and enabling them to provide more beds for patients. The case was that of a poor man who fractured his fibula. He was kept in hospital for the night. A plaster-of-Paris bandage was, after a few hours' rest, applied, forming a splint, and as the bed was wanted for a worse case, the poor fellow was treated as an out-patient and sent home, crutches being supplied to him by the hospital without charge, though the contrary has been alleged. His circumstances were poor and he applied at and was admitted into the Strand Workhouse. It is to be regretted, perhaps, that such a case should have to be sent out of a London hospital so quickly. But, as Dr. Steele points out, it is inevitable, unless the hospitals are better supported. Many fractures of the fibula can be dealt with summarily, as in this case. It is from want of charity that many patients cannot be supplied with a bed. But the authorities cannot put a quart into a pint pot. They must give their beds to the worst cases, and make out-patients of those for whom warmer charity would find a bed. Let the public realise that it is alone responsible for the straitened accommodation of the hospitals, and for this case being sent to a workhouse. Some such fate is likely to threaten all hospital patients unless more men like the founder of Guy's are forthcoming, and that quickly and in considerable numbers.

QUININE IN PNEUMONIA.

AT a recent discussion in the New York Academy of Medicine there was a general consensus of opinion upon the inability of quinine as an antipyretic in the treatment of acute pneumonia (*Boston Medical and Surgical Journal*, March 3rd). The subject was introduced by Dr. J. H. Ripley, who related his experience of the administration of the drug in large doses in cases where the temperature exceeded 108°. In two cases no reduction of temperature occurred; in two there was a slight rise in the temperature. The reduction that it did usually produce never lasted for more than from two to four hours. Not only, then, was quinine to be regarded as feeble and uncertain in antipyretic effect, but it was harmful from disturbing the digestive functions and producing cardiac and nervous depression. In one case opisthotonos was noticed; in many epistaxis; in one marked albuminuria with renal casts. Nor did it shorten the natural course of the disease. Dr. Fruitnight's experience coincided with that of Dr. Ripley; but he prescribed it for its tonic effect in small doses. Dr. Castle found that, if given in antipyretic doses, it must be at the expense of the nutrition of the patient, and during the last five years he had almost entirely abandoned the remedy in pneumonia. Dr. Billington, to obviate gastric disturbance, had given the drug in the form of a suppository. He also had been disappointed in its use as an antipyretic in pneumonia. Dr. Emmett Holt had given as much as sixteen to thirty grains a day to children from one to one and a half year old in cases of pneumonia, and felt that as an antipyretic it was useless in small doses and dangerous in large. Far better results were obtained from the cold pack. He

Digitized by Google

had now discarded the drug in acute pneumonia, but found it of marked advantage in convalescence. Dr. A. Jacobi, the President, remarked on the changes in opinion with respect to quinine; he had himself always prescribed from six to twelve grains to children, usually in full dose in two instalments in the morning when the remission occurred. He thought the condition of the stomach in the febrile state accounted for some of the intolerance mentioned, and preferred hypodermic injection of the carbamide. Dr. Ripley, in reply, said that in a large number of cases the quinine had been given hypodermically in the form of strong solution of the muriate; but Dr. Jacobi remarked that it was not safe to use too concentrated a solution for hypodermic injection, and mentioned a case in point.

ANTHRAX IN CHESHIRE.

A SEVERE outbreak of anthrax has occurred in Cheshire. It arose a fortnight ago on a farm in the township of Aston, several cattle, sheep, and pigs having been attacked; and the latest advices prove that the epidemic has by no means abated. The recent order of the Agricultural Department of the Privy Council has been issued none too soon, and the recommendations embodied in it ought to be strictly observed. We were struck by one of the remarks reported to have been made by the secretary of the Cheshire Chamber of Agriculture last week when introducing the fact of the outbreak to the notice of the members. He said that "no one had yet been able to point out the cause of this disease." Now if there is one infective disease the etiology of which is clearly established it is anthrax. The fame of Koch and Pasteur rests largely upon their discoveries in this direction, and the knowledge contributed by pathologists in this country on their investigations upon woolsorters' disease should surely be in the memory of scientific agriculturists. But we may be doing Mr. Rigby an injustice. He may merely have implied that the cause of the particular epidemic was unknown, and therefore the step taken by the Council of the Chamber of Agriculture to ask the Privy Council to send an inspector is to be commended. Isolated cases of anthrax have, we believe, lately occurred in other parts of the country, and it is highly important that no delay should take place in stamping it out.

ITALIAN MEDICAL CONGRESS.

THOSE of the profession who purpose spending their holiday next autumn at the Italian lakes or in the art cities of the Lombardo-Venetian territory might do worse than "enter an appearance" at the Congress of the Associazione Medica Italiana, to be held at Pavia. It will take them but little out of their way, and will, like its recent predecessors at Siena and Perugia, provide them with much that is novel, interesting, and instructive. If they are so minded, they can take part in its proceedings, French or even English being a recognised medium of communication at such gatherings. They will also make acquaintance with not a few celebrities in the healing art and its cognate sciences, who will be glad of an occasion to requite the hospitality which won so many a continental brother at our great International Congress just ten years ago. Full details of the meeting, including the date of its opening, its duration, and an outline of its business, may be had from the secretary of the "Comitato Pavese," now sitting. Pavia, for its own sake, is full of interest. To say nothing of its churches, its palaces, and its far-famed Certosa, rich beyond any other ecclesiastical edifice in Italy in early Renaissance and Roman-Gothic features, it has its university, once the rival of Padua in attractions for English physicians, and immortalised by teachers like Spallanzani, Tissot, Volta, and Scarpa, whose monuments ennoble its spacious courts and grand old library. Its imposing hall, completed in 1845 at a cost of 200,000 fr.; its Teatro Fisico, with statues of Galileo and Cavalieri, and a bust of Volta; its wealth of literature in medicine and physics, embodied in a collection of over 200,000 volumes, are some among the many points of contemporary interest possessed by the Ticinum of antiquity, the "domus paterna" of Cornelius Nepos, the scene of famous deeds under Theodoric, Charlemagne, and Francis I. The congress at which the profession is now invited to assist will be the twelfth of the series, and its working committee are not likely to fail in rendering it worthy of its predecessors and of the historic and scientific associations of its picturesque seat.

SPAYING IN THE STATES.

ON Dec. 2nd, 1886, at the Obstetrical Society of Philadelphia, Dr. Kelly related a case in which he had removed the ovaries and tubes for subinvolution. We cannot do better than give the words of the report in the *American Journal of Obstetrics*:—

"Dr. Kelly considers the indications in this case so well defined and new that he designs making it the subject of a more detailed critical communication. The patient, about thirty-five years of age, had raised five children, but for several years had suffered from constant soreness of the whole hypogastrium, a spot of intense burning pain to the left of the uterus, and a constant dark leucorrhœa. The menstrual congestions greatly increased her symptoms, which were again aggravated by several early abortions. She had been under excellent treatment before coming to Dr. Kelly, and had been carefully treated by him, but with only moderate temporary improvement. Dr. Kelly then decided to stop the menstrual function, with a view to checking the periodical determination of blood to the uterus, and finally bringing about complete involution of the organ. The ovaries and tubes were removed through an incision two inches long. The ovaries were full of pea-sized follicles, and covered with a dense capsule, and were probably (not, however, in consequence of these appearances) diseased. The speaker insisted that the operation here had no reference whatever to any disease which might be found in the appendages, but the sole indication lay in the state of the uterus; the ovaries, whether diseased or not, were removed to correct that trouble. The recovery was as perfect and free from disturbance as any slight injury, and the patient was up in the next room on the fourteenth day, when the uterus was free from tenderness and already rapidly undergoing involution.—Dr. Chas. Meigs Wilson considered oöphorectomy a resort of doubtful propriety as a remedy for metritis; for, as the menopause occurring physiologically would not stop such an inflammation, we would scarcely expect it to be of greater benefit when the result of an operation. He doubted the moral right of exposing the patient to the risks of abdominal section for such a condition."

We refrain from commenting on this case, and prefer to leave our readers to draw their own conclusions.

ITALIAN BEGGARS IN LONDON.

IT seems that the padrone system of importing beggars from Italy having been checked by the combined action of the Italian and English Governments, this device has been superseded by a system of parental emigration with families introduced for the same purpose. There is only one real remedy for this begging system, and that is for the free-handed—we will not say the benevolent, for it is not benevolence to encourage dependence on alms—to steel their soft hearts against entreaties and refuse to give money in the streets. If this were generally done we believe there would be much less real distress. "Begging" is a trade that ought to be starved out of existence, if only because it is a bad one for those engaged in it.

SCIENTIFIC MEMOIRS BY INDIAN MEDICAL OFFICERS.

WE note with pleasure the appearance of Part II. of the "Scientific Memoirs by Medical Officers of the Army of India," edited by Surgeon-General Simpson, M.D. The volume contains an interesting account by Surg.-Major D. D. Cunningham upon the effects which sometimes follow injection of choleraic comma bacilli into the subcutaneous tissues in guinea-pigs. Three out of five of such experiments were productive of symptoms closely resembling those of cholera, with abundant development of the comma bacilli in the intestine, and also in the peritoneal fluids. Dr. Cunningham's results are suggestive of the possibility of infection other than by the digestive tract, but he would doubtless be the first to admit that the experiments are hardly conclusive. Four papers deal with subjects of botanical and physiological interest. Surgeon-Major Barclay describes the life-history of a new Æcidium on Strobilanthes dalhousianus; and in another paper describes the character of Æcidium urticæ. Surgeon-Major Cunningham records his observations on the Phenomenon of Gaseous Evolution from the flowers of Ottelia alismoides, a plant very abundant in the tanks in and around Calcutta. Surgeon-Major King discusses the Fertilisation of Ficus hispida. Lastly, Surgeon-Major Bomford contributes a note on Eggs of Distoma (Bilharzia) hæmatobium, found in transport cattle, Calcutta. The parasite has never been found in India before, and the affected cattle had not been in Egypt.

JUVENILE INTERMITTENT ALBUMINURIA.

CONSIDERABLE interest attaches to cases of cyclical albuminuria, for their pathology is unknown, and perhaps is different in different cases. The causation of mere intermittency of symptoms generally has not received adequate attention. M. Teissier has collected a fresh series of ten cases of cyclical albuminuria. He lays stress on the following features: A separation of oily matter on the urine, and the presence in it of brilliant bluish or metallic-looking spangles; the absence of true casts, though cylindroids possibly of mucus, and sometimes drops of fat, may be detected with the microscope; the slightness of the subjective symptoms, which may consist of mere vague feelings of malaise, of pain in the back, of weakness, or of pains in the limbs. Neuralgic troubles are rare. There is great nervous excitability or impressionability. Physical examination has never revealed the "bruit de galop." The lowness of arterial tension, which is calculated to be equal to a column of mercury sixteen to seventeen centimetres high, is important as an item in the differential diagnosis of cyclical albuminuria from interstitial nephritis. Dilatation of the stomach was observed in three cases. Three patients had had eczema or urticaria. Neither œdema nor "dead fingers" was noted. Speaking generally, the aspect of the patients is one of good health. The complaint, if such it can be called, is commonly curable; but slight relapses may recur under the influence of fatigue or violent impressions. The age that is most liable to the affection is ten years from puberty onwards; males suffer more than females. Violent exercise and excessive emotional excitement are direct causes. Teissier does not accept the mechanical theory of Bar, nor the theory of disturbance of the glomerular circulation of Magnin. His own view, propounded two years ago at Grenoble, he now believes to be insufficient to explain all the phenomena. A slowing of the combustion of albumens will not explain the presence of fatty matters or the increase of urea in the urine. His present position is to regard the malady as due to over-action of the liver, which is the factory for urea, uric acid, and fatty matters. In treatment the importance of hygiene is very great. These patients are perhaps predestined to become gouty. Shampooing, plenty of fresh air, prohibition of alcohol and white wines, and moderate exercise, are to be prescribed for these young men. Arsenic, inhalations of oxygen, cold baths, bromides and hydrotherapy, tannin, benzoate of soda, &c., are recommended, but especially sweet spirits of nitre, twelve to fifteen drops a day (alcool nitrique); milk eggs, and ham may be eaten, but not fish; thermal waters are good.

THE ERASMUS WILSON BEQUEST.

OUR contemporary, the *Glasgow Herald* of the 16th inst., contains the account of an anti-vivisectionist meeting recently held in Edinburgh. The object of this meeting was "to consider the memorial recently presented to the Royal College of Surgeons praying that the bequest by Sir Erasmus Wilson should be devoted to the foundation of an institution for physiological and pathological research." We have already referred to this petition and to sundry comments by anti-vivisectionists which the petition has called forth. We should prefer to let the matter rest here, were it not that the mover of a resolution stoops to deliberate misrepresentation when he says that "the proposed institution would simply be an institution where from week to week men would follow *no other pursuit than experimenting upon living animals*." (The italics are our own.) Such a statement made concerning members of the medical profession and the managing body of the Royal College of Surgeons is simply a libel. There is not a tittle of evidence in support of such a statement—a statement which betrays profound ignorance of scientific research and the modes in which it is conducted, and exhibits an exaggeration in tone which can only be regretted.

WHAT WAS THE CAUSE OF DEATH?

A CURIOUS case has recently been investigated by the coroner at Cardiff. It appears that a lad named James Dunscombe, aged seven, was taken ill on March 7th, 1887, and died in about twenty hours. His symptoms were chiefly of a convulsive nature, but there was also some vomiting and pain at the stomach. The spasms were of a tonic character. There were marked remissions, but according to the report there were no intermissions. This, taken in conjunction with the fact that deceased lived for the greater part of a day after his first seizure, seems pretty conclusive that the illness was not due to strychnia poisoning. Unless an enormously large dose of strychnia has been taken so as to cause the spasms to follow one another so rapidly as to appear almost continuous, there are well-marked intermissions; and if the dose is large death ensues in a correspondingly short period. Moreover, in this case there was not a tittle of evidence to show that deceased had taken anything which could have contained strychnia; and lastly, an analysis of the contents of the stomach failed to detect the alkaloid. It is said a trace of lead was found in the walls of the stomach; but the analyst evidently thought the quantity too minute to account for the attack of spasms. We do not know whether it was suggested that deceased might have succumbed to saturnine epilepsy from chronic lead poisoning; if so, we should have thought that some mention would have been made of the gums and the muscular coat of the intestine. It could scarcely be contended that the case was one of acute lead poisoning. Were the spasms due to tetanus? They were quite consistent with such a hypothesis, but then no wound of any kind could be discovered. Nevertheless, we are not disposed altogether to discard the theory, for the solution of continuity may be extremely small and hidden away in some recess of a mucous membrane, so that nothing short of a

Digitized by Google

minute and exhaustive search might succeed in finding it. We are much more inclined to acknowledge tetanus as the explanation of the symptoms than strychnia poisoning. There seems to have been no ground to suspect hydrophobia. It is just possible that the phenomena presented were due to the onset of some specific fever. In one instance we can recall a somewhat similar condition obtained in typhoid fever. To sum up, then, we conclude that the facts as presented fit in better with the theory of tetanus than any other. It is curious that two other children of the same family succumbed to convulsions, one of them dying from hydrophobia. We agree with the opinion of the medical man, who said at the inquest there might be a family tendency to convulsions, in the sense of instability of the reflex centres.

TYPHOID FEVER IN MELBOURNE.

IN an address delivered before the Medical Society of Victoria, Dr. James Jamieson, health officer of Melbourne, drew attention to the comparative prevalence of typhoid fever in that city and suburbs, and the causes of it. He pointed out that whereas in England the fever mortality had greatly and steadily diminished—viz., from 17,910 in 1870 to 7978 in 1883, in Victoria there had been no apparent diminution, even taking into account the increase of population, the average annual mortality of the five years 1871-75 being 360, and that of 1881-85 being 473. He also pointed out that the mortality in Melbourne from fever was much higher than in other parts of the colony; whereas in England the rate in the twenty chief towns is less than in the rural districts. Discussing the various etiological conditions, he dwelt first upon the water-supply of Melbourne, and showed that it could not be charged with the propagation of the disease. Nor was he able to trace during 1886 any cases due to infection of the milk-supply. As to direct contagion, isolated cases occurred, but not sufficient to account for the great and continued prevalence of the disease. He next discussed the influence of the pan system of night-soil collection and removal, which is carried on in Melbourne; and although doubtless accompanied by considerable risk, as well as discomfort, he was unable to adduce positive proof of its being a source of contamination. Lastly, he adduced the imperfection of drainage as the most important of all the conditions to which the prevalence of typhoid fever could be attributed; and gave instances in which this defect in sanitation was responsible for outbreaks of the disease. He quoted the experience of European cities as showing the efficacy of improved drainage in diminishing the mortality from typhoid fever; and contended that what Melbourne needs is a complete system of drainage, which should not merely carry off storm-waters and lessen subsoil dampness, but be utilised for the rapid and complete removal of excrementitious matters. He advocated the formation of a metropolitan board of works empowered to carry out this great and much-needed improvement, in the realisation of which the chief difficulty was one of finance. We are glad to note these opinions of Dr. Jamieson, and trust he will succeed in convincing the inhabitants of Melbourne of the need and importance of the sanitation he advocates.

THE CARRIAGE-TAX.

THE carriage-tax in its present form has few friends in the north of England, especially at Newcastle-on-Tyne, which is in some respects the headquarters of an agitation against its continuance, and, notwithstanding the unfavourable reply of Mr. Goschen to the late deputation, very strong pressure has been put on the northern members of Parliament by the profession there in prospect of the forthcoming budget, with a view to the modification of the tax.

THE APOTHECARIES' HALL OF IRELAND AND THE KING AND QUEEN'S COLLEGE OF PHYSICIANS.

THE King and Queen's College of Physicians in Ireland has published a statement in reply to the request of the General Medical Council that the College should reconsider the Conjoint Scheme for Ireland, with a view to admitting the Apothecaries' Hall, Dublin, to take part therein. In this statement the history of the apothecaries in Ireland is traced minutely, and it is maintained that by law their functions originally had strict reference to the preparing of drugs, inspecting and directing chemical and compound preparations and experiments, and the examination of persons wishing to become apprentices to and learn the business of apothecaries. Contrary to the opinion of Sir Richard Bethell in 1860, it is maintained by the College that there is no analogy between the Hall in Dublin and the Apothecaries' Society in London. Two or three points, however, in the other direction are admitted. It is allowed that the Army, Navy, and Local Government Board recognise the certificates of the Hall, and that there are some practitioners in Ireland holding no other qualification than that of the Apothecaries' Hall, Dublin. In the final result the King and Queen's College say that the Medical Council should decline to appoint assessor examiners to the Apothecaries' Hall, Dublin, and they (the President and Fellows) have no option but to adhere to their resolution to exclude the Hall; and they add that, if an inferior and low grade of practitioners is created and perpetuated, the responsibility will rest with the General Medical Council, and not with the King and Queen's College of Physicians.

INEQUALITY OF THE PUPILS IN HEALTH.

DR. G. T. IVANOFF, referring to some observations by Dr. Pasternatski on the inequality of the pupils in internal diseases (see THE LANCET, Jan. 15th, 1887), communicates to the *Vrach* (No. 7) the notes of a series of observations made by himself in 1885 on a number of healthy subjects, which show that inequality of pupils is a very usual condition when no disease at all is present. Of 134 persons the pupils were equal in 12; the left being the larger in 73, and the right the larger in 49. In these persons the two sides of the face were also carefully measured, with the following results: Of the 12 with equal pupils, the two sides of the face were equal in 3; the right side being the larger in 5, the left in 4. In all the 122 cases where the pupils were unequal the two sides of the face were also unequal; the right being the larger in 27, and the left in 95.

HEALTH OF CALCUTTA.

THE report of the health officer for the fourth quarter of 1886 shows the deaths in Calcutta to have amounted to 3829, which would give an annual ratio of 35·23 per 1000. This is under the average of the preceding decades, in only four years of which has the number of deaths been lower. The returns show a considerable reduction in the deaths by fevers and by dysentery and diarrhœa, but there has been unfortunately a considerable increase in those by cholera, which amounted to 942, as against an average of 383. This disease, which had been prevailing during the third quarter of the year, reached its highest number of deaths in the last week of November, since which date it has continued steadily to decline. Dr. Simpson points out two important facts in connexion with its prevalence in particular localities. "First, a large grouping took place around tanks; and, secondly, most of the cases took place in those localities where there was great scarcity of water"—that is, we presume, water fit for drinking. The water in the tanks of the Bustees was "very foul." He also again calls attention

Digitized by Google

to the necessity for an amended Municipal Bill, with power to enforce "building regulations which will effectually prevent huts and houses being built irrespective of ventilation, drainage, air space, and means of scavenging." We are glad to learn that the Sanitary Commissioners have sanctioned the formation of the nucleus of a sanitary staff, by which inquiries may be made, under the direction of the health officer, into all cases of cholera, small-pox, typhoid fever, and other preventable disease, with a view to appropriate measures being adopted to arrest their spread.

THE MARQUIS OF SALISBURY.

RUMOUR has much exaggerated the recent illness of the Right Hon. the Marquis of Salisbury. The noble Premier has been suffering simply from the annoyance and feverish depression arising from an attack of what in ordinary parlance would be termed a severe cold in the head. Bronchitis has been mentioned in connexion with his illness. We are, however, able to state that no symptoms of this affection have been present. It is true that Sir William Jenner was in attendance; but merely, we would suggest, to enforce that rest from onerous and responsible duties so necessary, yet so difficult, to be obtained by one in the exalted position of his noble patient.

THE INTERNATIONAL MEDICAL CONGRESS.

THE programme of the proceedings of the Congress will not be completed till after the meeting at Chicago, in June, but it is expected that one of the general addresses will be delivered by Dr. Semmola of Naples, and another by Professor Austin Flint. Communications are expected amongst others from the following gentlemen:—Great Britain: Dr. W. Dunnett Spanton, Dr. Julius Althaus, Dr. W. M. Whitmarsh, Mr. Edmund Owen, Dr. R. Norris Wolfenden, Dr. Sidney H. C. Martin, Mr. Lawson Tait, Mr. Henry Power, Dr. Samuel Benton, Dr. W. Macewen, Dr. G. Feilding Blandford, and Dr. Geo. H. Savage. Ireland: Dr. Thos. More Madden. France: Dr. E. Landolt, Dr. P. Menière, Dr. M. C. Marquis Nadaillac, Professor Dr. A. Charpentier, Dr. J. Ameda-Doleris, Dr. Victor Aud'houi, and Dr. Max Durand Fardel. Germany: Professor Dr. Hegar, Professor Dr. Gusserow, Dr. A. Oldendorff, Dr. L. Lewin, and Dr. J. Veit. Hungary: Professor Joseph Korosi. Austria: Professor Dr. Gustav Braun, Professor Dr. E. H. Kisch, and Dr. Emil Ehrendorfer. Belgium: Dr. Alf. Struebens. Switzerland: Dr. A. Cordes. Canada: Dr. Daniel Clark and Dr. MacCullum. Italy: Dr. Luigi Casiti and Dr. Domenico Perruzzi. We cordially wish the Congress every success.

PARA-MYOCLONUS MULTIPLEX.

DR. HELSINGFORS has described a case of this unfamiliar affection. It occurred in a man aged forty-five, whose father was an inveterate toper. The disease began at the age of sixteen, one year after the patient had had an attack of malarial fever. A convulsive attack, apparently caused by a severe fright, was attended with loss of consciousness. The day afterwards his thighs were the seat of involuntary shocks, often followed by movements in the thighs, later in the arms, and rarely in the face. Ever since that time the shocks had continued, varying a little in frequency and intensity, without, however, disappearing for a long time together, and of late they had increased in frequency and intensity. Movement, emotions, and fatigue increased the movements. Small doses of brandy lessened the shocks, but inebriety might lead to a convulsive seizure and to augmentation of the chronic affection. His general health is said to have continued good all through, and he has never had any pains. Contractions of the facial muscles were observed, especially about the mouth. The chief muscles affected in the arms were the long supinator, biceps, triceps, deltoid, and carpal extensors. The shock extended throughout the whole muscle, and was often followed by a corresponding movement. The muscular contractions were often isolated; sometimes an irregular series of arhythmical contractions were to be observed in the same muscle. The intensity and frequency of repetition of the contractions were rather variable; a common interval was fifteen to twenty seconds. The contractions might be symmetrical without necessarily being isochronous. The movements did not interfere with the manual movements; he could write without trouble. Similar kinds of movements were noted in the muscles of the thigh. Attempts to evoke the ankle clonus were very efficient in calling forth movements in the thigh muscles. The diaphragm, as well as the face, was the seat of the spasms. The case differs from those recorded by Friedreich, Lowenfeld, Remak, and Marie in the last-mentioned facts, and, as in Seeligmuller's case, voluntary movements favoured the occurrence of the involuntary contractions. The knee-jerks were exaggerated in most cases, but diminished in the one now mentioned. The hypothesis of Friedreich supposed the motor cells of the spinal horns to be the seat of a hyper-excitability—a supposition which is so obvious as to be of no pathological value. We want to know why these nervous centres overact.

HALIFAX SUB-TOWNSHIPS AND THEIR MEDICAL OFFICER OF HEALTH.

AN effort is being made to break up the combination around Halifax for which Dr. Britton has hitherto acted as medical officer of health. At a public inquiry conducted by Mr. G. Kennedy and Dr. Frederick Barry, inspectors of the Local Government Board, Dr. Barry opened the proceedings by giving a summary of the advantages of combination over a large number of local appointments of medical men engaged in practice. The relative advantages of the two systems were considered in THE LANCET of Jan. 24th, 1885, and we have since then seen no reason to alter our opinion on the subject. In this special case, even those who advocated a break-up of the existing system had no complaint as to the manner in which Dr. Britton had performed his duties; and his supporters were strongly in favour of continuing the combination. We should much regret any alteration, for the simple reason that we do not believe a change can, in this instance, result in increased efficiency. Unfortunately, the proceedings at the inquiry were of a character not calculated to favour the views of the central authority, and many of those engaged in it came into open conflict with Mr. Kennedy, with the result that language was used on both sides which will not tend to a satisfactory settlement.

NURSING IN WORKHOUSE INFIRMARIES.

MR. SAMUEL BENTON lately read a paper on "Nursing in Workhouse Infirmaries" to the members of the Hospitals Association. It is a subject which requires constant attention. The conclusions he arrived at, and the soundness of which cannot be questioned, were as follows:—

1. The matron should be a lady and a trained nurse. 2. In building these infirmaries more accommodation ought to be provided for the nursing staff. 3. There should always be probationary nurses in training (at all events in the large infirmaries) to fill up vacancies as they occur. 4. The large infirmary and workhouse maternity wards ought to be thrown open for the training of midwives. 5. Every encouragement should be given by the guardians to the medical officers to instruct the nurses and interest them in their work by means of lectures and classes.

THE PRESIDENCY OF THE ROYAL COLLEGE OF PHYSICIANS.

THE day for the annual election of a President by the Fellows of the Royal College of Physicians will shortly come round (Monday, April 4th). If there were any doubt on the last occasion as to who might be chosen to occupy the presidential chair, there can be none now. In the minds of some the habit of not re-electing the President beyond a term of five years had almost come to be regarded as an established rule. But happily that custom was broken through last year, and the precedents of earlier years in the history of the College were followed when by so large a vote the Fellows declared that Sir W. Jenner should form an exception to the rule. Once more they may be trusted to signify their approval of his services to the profession by extending still further his term of office.

MANCHESTER CENTRAL MEDICAL SOCIETY.

THE first annual report of this Society has just been published, and the record of success which it contains seems to prove that such a Society was, as anticipated by its promoters, required by the profession in Manchester and its vicinity. Formerly there was but one medical society in the city, and it was felt that this, for so large a number of professional men, was inadequate; that there must be many valuable experiences lost for want of opportunity to bring them forward; and that there was ample room for a society founded somewhat on the lines of the Clinical Society of London, in which subjects of immediate interest to the medical practitioner might be dealt with, discussions raised on diseases more frequently met with in private practice than in hospitals, and on the use of new drugs. The members number about 120. The library and reading-room have been throughout the year extensively used, and the meetings of the Society well attended. The permanent rooms of the Society are at the Victoria Hotel, Manchester, where many other scientific societies also hold their meetings.

DIPHTHERIA IN YORK TOWN.

THE Sanitary Authority of Frimley are not yet free from anxiety concerning diphtheria in their district. Four more cases of this disease have occurred in York Town, two of which have proved fatal. At a meeting of the board held last week the clerk was instructed to write to the Local Government Board, stating that the authority wanted a report on the recent outbreak, as the district was still threatened with diphtheria. It is, however, no matter for surprise that further cases of diphtheria have occurred in a district in which this disease was freely disseminated a few months ago; the opportunity for its development will likely enough be given by some of the earlier cases. The sanitary authority can hardly expect that the Local Government Board are prepared to issue a report at a short notice on a matter which requires much consideration.

MEDICAL MISSIONARY INSTITUTIONS IN LONDON.

THE March number of *Medical Missions* gives an illustrated paper on the medical missionary dispensaries at present existing in London. The St. Giles's Medical Mission in Endell-street deals annually with some 5000 persons; the Bethnal-green Medical Mission receives upwards of 400 persons in its hospital and treats about 6000 in its dispensary; the Marylebone Medical Mission in Edgware-road relieves about 4000; the Stepney Medical Mission (which is associated with Mr. Barnardo's work) relieves about 2500; the Clapham-road Mission is confined to women and children, and its staff consists of two qualified ladies, who attend about 3000 persons annually; the Mildmay Mission in Cannon-street, Whitechapel, is limited to the Jews, of whom it relieves annually about 5000, or one-tenth of the whole Jewish population of London. These six medical missions, then, relieve some 25,000 persons annually, and thus probably save other hospitals and parochial medical officers a large amount of labour without trenching upon the province of the general practitioner to any appreciable extent, for the patients who are attended either in the Mission dispensaries or at their own homes are almost always miserably poor—often, indeed, in want of the necessaries of life.

THE CLIMATOLOGY OF SPAIN.

IN a paper read before the Academy of Medicine in Madrid on change of climate in the treatment of disease as met with in that city, Dr. Don Iglesias y Díaz, referring to cases of chronic bronchitis with or without tubercle, and various pulmonary affections which, he said, were very intractable in the changeable winter climate of Madrid, mentioned as suitable localities Alicante, Valencia, Murcia, and Cartagena in the east, and Malaga and its surrounding district in the south. While in Madrid the mean annual temperature is about 57° F., and the difference between the maximum and minimum temperatures 95°, the mean temperature in Valencia is 62·6° F., in Alicante 64·4° F., and in Cartagena and Malaga 66·2° F., the variations in all these places being also very much less than in Madrid. The driest localities where there are fewest fogs and least rain are the districts round Cartagena, Alicante, and Elche; then come Murcia, the south of Valencia, and parts of Andalusia; while most of the west and north coasts are damp, and Bilbao and Santiago de Compostella extremely so, the aqueous vapour there having a tension varying from 1000 to 2000 millimetres. For dyspeptics Don Iglesias recommended the southern shore of the Bay of Biscay, where the air is cool and moist.

PROFESSOR POLITZER.

THE old pupils and friends of Professor Adam Politzer have arranged to present him with his portrait as a memento of his great services to aural surgery during the twenty-five years he has been teaching at the University of Vienna. The presentation will take place at the meeting of the Otological Association, in Vienna, at Easter. The subscription (8s.) may be sent to any of the committee: Professor Vittorio Crazzi (Florence), Dr. Antonin Joly (Lyons), Dr. Eugen Morpargo (Trieste), Dr. E. Pius (Vienna), Professor Urban Pritchard (London), Dr. F. Rohrer (Zurich), Dr. A. Rühlman (St. Petersburg).

DIABETIC COMA.

THE latest interpretation of the phenomena of diabetic coma has been to attribute them to poisoning by acids formed within the system, probably from the glucose. It may be remembered that Dr. Ralfe developed this idea at the Pathological Society nearly five years ago, basing his statements upon the similarity in symptoms to those of acute yellow atrophy and poisoning by organic acids, and upon the presence of aceto-acetic acid in the urine. Acetonæmia, then, would be only one link in the chain of processes inducing diabetic coma. But since experimentally neither acetone nor aceto-acetic acid have been found competent to produce phenomena analogous to those of diabetic coma, the way was still open to the discovery of other acid products which should have a toxic effect. This seems to have been supplied by Stadelmann and others in the detection of oxybutyric acid and the determination of greatly decreased alkalinity of the blood. M. Lépine (*Rev. de Méd.*, March, 1887) discusses this ques-

Digitized by Google

tion and relates a case in which, in accordance with Stadelmann's views, diabetic coma was treated by intravenous injections of alkaline fluid—viz., bicarbonate of soda 34 grms., chloride of sodium 8 grms., water 1½ litre. Intravenous saline injection has, it may be remarked, been practised before in diabetes on other grounds—notably by the late Dr. Hilton Fagge and by Dr. F. Taylor (see Guy's Hospital Reports, 1881), but with no more benefit than in M. Lépine's case. At the same time, the alkaline treatment of diabetes is justified, according to M. Lépine, not so much because of neutralisation of free acid in the blood, since mere neutralisation will not annul the toxic action of the acid, but on the ground that alkaline injections may assist in breaking up the acids and in favouring their elimination. In the case related he found that oxybutyric acid disappeared from the urine after the injections. Prior to the measure, both the blood and urine yielded this acid in parallel amount. Of course, as he remarks, to prevent the accumulation of the poison in the system is not everything; a way may be found some day to prevent its formation.

THE EMPEROR WILLIAM AND HIS PHYSICIAN.

ON the eightieth birthday of the German Emperor, Dr. von Lauer, his Majesty's medical attendant, received the title of "Excellency" and a gift of 150,000 marks. On the 22nd inst., on the occasion of his illustrious patient's ninetieth birthday he is stated to have received 300,000 marks. The post which Dr. von Lauer occupies is far from being a sinecure, and it is pleasing to note that at a period of national rejoicing his skill and care have neither been unnoticed nor unrewarded.

THE LONDON HOSPITAL.

THE main question of the dispute at the London Hospital to which we alluded last week had its origin, we understand, in a difference of opinion between two bodies of the students—that is to say, between those who have entered the full college course of lectures and hospital and those who have entered as full students of the hospital *only*, the former claiming a precedence in the holding of resident appointments, and the latter asserting equal rights in this respect. The matter has now been referred to a college board, who will decide as regards existing rights as expressed in the wording of the prospectus.

EFFUSION OF BLOOD INTO THE KNEE-JOINT.

DR. BONDESEN, writing of the results of treating effusion of blood into the knee-joint with and without puncture of the joint, as shown by the records of the Copenhagen Communal Hospital for the last twenty years, during which 119 cases of the kind have been admitted, states that the percentage of complete cures was eighty-six in the cases punctured, against sixty-three in those not operated on; and, further, that the average stay in hospital of the former class of cases was twenty-two days, against an average stay of thirty-eight days on the part of the others. He considers the best practice is to puncture in all cases, and, if necessary, to lay open the joint, using of course antiseptic precautions.

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

THE deaths of the following foreign medical and scientific men are announced:—Dr. Adrian Segura, Professor of Pathology in the Medical School of Mexico, and Director of the Hospital of San Pablo in that city. Dr. Metardier of Bordeaux, author of various works on Hygiene and of Reports on Epidemics, especially on the Cholera in Spain, which he studied carefully on the spot.

THE JAPANESE PHARMACOPŒIA.

THE new Japanese Pharmacopœia has just appeared, and it is hoped that an end will now be put to the inconveniences which have hitherto existed in Japan of there being no official standard for medicines. The chemists obtain their drugs from America, England, France, and Germany, and as the preparations vary considerably in strength, all kinds of confusion arose. The new Pharmacopœia was undertaken some twelve years ago, and in 1880 a commission was appointed by the Government to carry out the work. This commission has held 155 sittings. It was found advisable to write the text of the Pharmacopœia originally in German, that being the language most generally understood by the members of the committee. The official text is, however, Japanese, and there is also a Latin translation. The number of preparations is 475, which are named first in Japanese and then in Latin. The general character of the work is similar to that of the English and German Pharmacopœias.

THE NEW M.D. DEGREE FOR LONDON MEDICAL STUDENTS.

A CROWDED meeting was held at the Westminster Hospital Medical School on Tuesday last, at which Mr. Macnamara occupied the chair. Mr. F. J. Simson proposed, and Mr. A. S. Gubb seconded, a resolution supporting the scheme of the Conjoint Board. The chairman, Dr. De Havilland Hall, and Mr. Black also spoke in favour of the resolution, which was carried with only three dissentients.

THE NAVAL MEDICAL SERVICE.

THE course of instruction at Haslar Hospital for the surgeons who entered the Navy in February last was opened on the 10th inst. by Sir J. Watt Reid, K.C.B., the Director-General of the Medical Department, in the presence of a distinguished company. The proceedings on the occasion will be noticed more fully in our next issue.

CHOLERA PRECAUTIONS.

IN furtherance of the efforts of the Local Government Board to secure adequate preparations against the entrance into this country of cholera by sea routes, an inquiry was held last week at Bangor to consider the proposition to erect a small hospital on Puffin Island, at the entrance to the Menai Straits. Curiously enough, opposition came from such watering-places as Beaumaris, Penmaenmawr, Llanfairfechan, and Llandudno, the places of all others that should seek to assist in proceedings directed against the importation of sea-borne infection.

FOREIGN UNIVERSITY INTELLIGENCE.

Erlangen.—The names selected for the chair of Midwifery with the post of Director of the Lying-in Institution are Dr. Frommel of Munich, Dr. Pawlik of Vienna, and Dr. Sänger of Leipsig.

Kharkoff. — Dr. M. Lomikovski has been appointed Extraordinary Professor of Medical Diagnosis; Dr. Podres, Extraordinary Professor of Surgery; and Dr. P. Iassinsky, Extraordinary Professor of Midwifery and Gynæcology.

Leipsig.—Professor Zweifel of Erlangen has been appointed to the chair of Midwifery and to the post of Director of the Lying-in Institution.

ON the 18th inst. the Carlisle medical officer of health reported to the sanitary authority that an outbreak of typhoid fever had taken place through infected milk. Every precaution has been used to prevent the spread of the infection.

Digitized by Google

THE Port Said Hospital for Seamen has been erected on the new site near the lighthouse, a medical officer and nurses have been selected, and Lady Strangford goes to Egypt to inaugurate it before May. A sufficient sum to commence working has been guaranteed by the members of the committee, and the Princess of Wales has contributed £500 from a fund under her control.

THE Swedish Government has authorised the appointment of a medical officer to all the higher grade schools for the purpose of watching over the health of the pupils and the hygienic condition of the school. His salary is to be from about £6 to £9, with a capitation fee of about 1*s.* 1*d.* on each pupil.

ON the 23rd inst. the Glasgow University Court appointed out of a number of applicants the following gentlemen:—Botany: George Murray, London. Natural History: R. E. C. Leith, M.A., B.Sc., M.B., Edinburgh. Chemistry: J. J. Dobbie, M.D.Sc., Bangor. Materia Medica: Wm. Whitla, M.D., Belfast.

THE Darlington School Board have ordered their schools to be closed for a time with a view to check the prevalence of measles and scarlet fever in the town.

JOHN TYNDALL, LL.D., F.R.S., has resigned his position as Professor of Natural Philosophy at the Royal Institution, which he has held since 1853.

WE are asked to state that the meeting of the Harveian Society announced to take place on April 7th is unavoidably postponed.

THE next meeting of the Clinical Society will be held on April 1st, instead of the 8th, the latter day being Good Friday.

Pharmacology and Therapeutics.

TINCTURE OF STROPHANTHUS.

FEW drugs have sprung more rapidly into favour than the African arrow poison strophanthus. It was introduced to the notice of the profession by the distinguished pharmacologist, Dr. T. R. Fraser, Professor of Materia Medica in the University of Edinburgh, who for fifteen years laboriously investigated its action both on man and the lower animals. It is now recognised as being not only a powerful heart tonic, but a most active diuretic. It is gradually replacing digitalis in popularity, and will in all probability in time entirely supersede it. It is not cumulative, and is especially indicated in all cases of cardiac affection attended with dropsy. It not only quiets the pulse, but by acting on the kidneys relieves the œdema and other attendant symptoms. It has also been found useful in purely functional irregularity. For a long time a difficulty was experienced in obtaining a thoroughly trustworthy preparation, but Messrs. Burroughs, Wellcome, and Co. have recently made a 1 in 20 alcoholic solution which answers every purpose. This new tincture has been submitted to Prof. Fraser, who, after a careful examination and subjecting it to various tests, found that it answered his requirements. The dose is from two to ten minims, and no hesitation need be felt in pushing it in suitable cases. It is made on a very large scale, some hundredweight or more being manipulated at a time, so that absolute uniformity of product can be guaranteed. The seeds alone are used, the husk and other parts being rejected. We have examined a specimen of the crude drug from which it is prepared, and have no hesitation in saying that it is the true species. The price of the tincture has been recently reduced, so that there is every prospect of its commanding a very extensive trial.

HOGG'S COCAINE TABLETS.

Messrs. R. Hogg and Son, Pharmaceutical Chemists, of 1, Southwick-street, W., have sent us specimens of their cocaine tablets containing one-twelfth of a grain in each. They are active, but are somewhat hard and unpalatable. For the treatment of affections of the mouth or throat, they would, we think, be improved by being prepared with a softer basis.

SALOL IN MEDICAL AND SURGICAL PRACTICE.

Salol has recently been extensively used in the Jewish hospital, Berlin, both in the medical and surgical wards. The *Therapeutische Monatsheft* publishes two papers on the subject from the pens of Drs. S. Rosenberg and L. Feilchenfeld. The former gives an account of the effect of the drug in acute rheumatism. He employed it at first in 15-grain doses six or eight times a day. In almost all the cases this had the effect of bringing down the fever and relieving the pain in the joints in from twenty-four to forty-eight hours. The number of doses was then reduced to from five to two per diem. The continuation of the treatment did not, however, appear to prevent the occurrence of complications, as peri- and endo-carditis and pleurisy; sometimes also singing in the ears, sweats, nausea, and vomiting occurred, and carboluria was always present for a time. The digestive organs were never affected for any prolonged period. Dr. Rosenberg thinks salol acts as a kind of "masked salicyl," being insoluble in the gastric juice, and thus having but little effect on the stomach. It does not, he says, decompose into phenol and salicylic acid until the pancreatic juice acts upon it in the duodenum. Notwithstanding its general advantages over salicylic acid, the latter should be used in very severe cases and when there are repeated relapses. Dr. Feilchenfeld employed salol in various surgical cases, both internally and as an external application. In cystitis and pyelitis he gave two or three 15-grain doses per diem with excellent results, and with little in the way of disagreeable symptoms beyond a green colouration of the urine of no particular moment. Externally salol was found very useful in ulcers of various kinds, and notably in a very obstinate case of bubo consequent upon a soft chancre, which had been operated on and treated with the strongest caustics without showing any disposition to heal. Salol, however, rapidly produced a change for the better, and cicatrisation soon occurred.

MYRTOL.

Myrtol is obtained from the distillation of the leaves of the myrtle; it is a liquid possessing the characteristic perfume of the plant. It is of less density than water, evaporates at the ordinary temperature, stains paper, but the stains disappear entirely. It has a warm, slightly acrid taste, soon followed by a sensation of freshness. It is said to be an excellent disinfectant and an energetic antiseptic, to stimulate the digestive functions, and to increase the appetite. In moderate doses myrtol acts as a sedative to the nervous system. It is eliminated by the respiratory and urinary passages. Myrtol appears to have the advantage over the balsams of not upsetting the stomach, thereby enabling it to be employed for a long time without leading to objectionable effects—e.g., dyspepsia. M. Linaris has had globules of myrtol prepared, each containing fifteen centigrammes of the pure liquid. The remedy does not appear to cause the same effects at all periods of diseases of the respiratory passages. In order to obtain the best results it should be employed with a view to combating subacute or chronic catarrhal affections, or it may be given at the termination of an acute attack of bronchitis when the fever has subsided. Another indication for its employment is an abundant opaque muco-purulent secretion. In these cases the secretion is diminished and rendered less purulent. M. Linaris has employed myrtol in chronic fetid bronchitis, catarrhal bronchitis, catarrhal asthma with paroxysmal attacks and palpitations, capillary bronchitis, and dilated bronchi. The average daily dose was six of the globules; they should be taken after meals: two in the morning, two in the daytime, and two at eventide.

SACCHARINE IN DIABETES.

Dr. Arnold Pollatschek of Carlsbad writes in a Hungarian journal on the importance of Fahlberg's saccharine or anhydro-ortho-sulphamide-benzoïc acid, as Stutzer calls it. Dr. Pollatschek quite agrees with Stutzer, Aducco and Mosso of Turin, and Salkowski of Berlin,—all of whose researches on the chemical, physiological, and therapeutical aspects of the

Digitized by Google

bject he quotes at some length—that saccharine is perfectly rmless. He finds that it may be given to diabetics for reetening purposes, neutralised as proposed by Prof. Leyden ith carbonate of soda. Dr. Pollatschek made an attempt cover the bitter taste of quinine with saccharine, but did ot succeed.

ROYAL COLLEGE OF PHYSICIANS.

AN extraordinary Comitia of the College was held on the 1st inst., Sir W. Jenner, Bart., President, in the chair.

A letter was read from the secretary to H.R.H. the rince of Wales, conveying his Royal Highness's thanks to ie College for the gift of a copy of Harvey's Prælectiones natomicæ.

A letter was read from the President of the General ledical Council addressed to the President of the College, ontaining the following resolution passed on Feb. 19th: That the Council, being of opinion that it would be ontrary to the interest of the public to have two competing xamining boards sitting in London, and that it is desirable hat the Royal College of Physicians of London, the Royal ollege of Surgeons of England, and the Apothecaries' ociety of London should arrange to hold a qualifying xamination conjointly, strongly recommend to these nedical authorities to reconsider their position with a view o such an arrangement; and meantime defer coming to a ecision on the application from the Apothecaries' Society of London of Feb. 12th." The letter went on to say that the Council felt it their duty to leave no way untried to effect combinations between licensing bodies, which had been done in Scotland, and partially in England and Ireland. By the combination proposed one strong licensing body would be formed in London.

The President pointed out that it was inaccurate to say that the Colleges in any way competed with the Apothecaries' Society.

It was moved by Dr. Dickinson, seconded by Dr. Habershon: "That this College, having already in full comitia in October deliberately considered the advisability of admitting the Apothecaries' Society of London to take part in the formation of an examining board for England, in consequence of a communication received from that Society, and having voted *nemine contradicente* against the inclusion of that body, having again fully considered the question, sees no reason for altering the decision previously arrived at by this College." In the discussion that ensued several Fellows took part, including Sir Dyce Duckworth, Sir Henry Acland, Dr. Handfield Jones, Dr. Wilks, and Dr. N. Moore. Sir H. Acland reviewed the previous steps taken to secure combination of bodies, and claimed that the attitude assumed by the Medical Council upon the question was in strict accordance with the spirit of the Medical Act, which was framed to ensure combinations of licensing bodies. The President strongly supported the motion, which was carried without a dissentient vote. A proposal by Dr. Wilson Fox that a statement of the reasons actuating the College should be appended to the resolution was withdrawn, it being felt that these reasons could be left in the hands of Sir Dyce Duckworth, the representative of the College on the General Medical Council.

Several communications regarding the movement of the two Colleges to obtain powers to grant degrees were read. One was from the secretaries of University College and King's College, to the effect that these Colleges intend to apply for a charter to grant degrees, and requesting a conference with the two Royal Colleges. Another was from the King and Queen's College of Physicians in Ireland, asking what steps the Royal Colleges were taking to obtain this power, and intimating their intention to make a similar application. A third from the Royal College of Surgeons of Ireland was to the same effect. A memorial from the Faculty of Medicine of University College, Bristol, asking that admission to the proposed degree should be extended to students in provincial schools, was referred, with the other communications, to the Committee of Delegates. A communication was read from the Association of General Practitioners enclosing resolutions passed at a recent meeting in Exeter Hall, dealing with the degree question, the conjunction with the Apothecaries' Society, and with the representation of Licentiates and Members on the governing body of the College.

A letter was read from the secretary to the Imperial Institute, inviting contributions from the Fellows of the College. It was resolved, on the motion of the President, to present a memorial to Her Majesty on the occasion of her jubilee; and it was also resolved to erect a statue or bust of Her Majesty, in commemoration of that event, in the new Examination Hall.

A report from the Committee of Management suggesting certain alterations in the examination regulations was adopted.

THE NAVY ESTIMATES.

THE Navy estimates continue to be furnished in a form which, so far at least as regards the medical service, makes it difficult, if not impossible, to give a clear statement of the expense involved. From the scattered details we gather that the *personnel* of the department is estimated to be 1 Director-General, 2 Inspectors-General of Fleets and Hospitals, 10 Deputy Inspectors-General, 65 Fleet Surgeons, 76 Staff Surgeons, and 217 Surgeons. The amount required for their pay and allowances is £136,573. There are on the half-pay list, but eligible for employment, 21 officers, for whom £5759 are taken. On the retired list there are 22 Inspectors-General, 70 Deputy Inspectors-General, 58 Fleet Surgeons, 62 Staff Surgeons, and 38 Surgeons, making a total of 250, whose retired pay amounts to £86,385. Provision is made for 3 head sisters and 15 nursing sisters in the Melville, Haslar, and Plymouth Hospitals, at an expense of £1367 for their pay and £235 for their uniform clothing. It is impossible to say what amount is required for the purchase of medicines and instruments, as under the vote in which these appear a great number of things are included which, though intended for the use of the sick, cannot be classed under either of these heads. We observe that, while the vote for the expense of carrying out the Contagious Diseases Acts disappears from the estimate, a sum of £2100 is to be taken "for contributions in aid of lock wards at Portsmouth and Devonport." For the purpose of carrying out sanitary work a sum of £2000 is to be expended on "sanitary alterations" in the Royal Naval College, Portsmouth; £800 for lavatories &c. to one block of wards in Chatham Hospital, and £620 for heating arrangements for washing-troughs in Plymouth Hospital. The only items under this head for foreign stations are a sum of £520 for "improvements to fever ward" in the hospital at Jamaica, and contributions of £1250 towards the drainage works at Halifax, and of £490 towards those at Malta.

THE IRISH MEDICAL SCHOOLS AND GRADUATES' ASSOCIATION.

THE annual general meeting of this Association took place on St. Patrick's Day, Thursday, March 17th, at 49, Berners-street, London. The following members of Council were present:—Sir Thos. Crawford, K.C.B., Director-General of the Army Medical Department; Dr. Macnaughton Jones; Prof. Yeo, chairman of Council; Prof. Macalister; Dr. Edward Waters, Chester; Dr. Gilbart Smith; Dr. Wm. H. White; Dr. Phillips, Reading; Dr. R. Fegan; Dr. J. H. Gibson; Brigade Surgeon Alexander, hon. treasurer; Dr. Jas. Stewart, hon. sec. for the Provinces; and Dr. P. S. Abraham, hon. sec. for London. Among the other members who attended were Inspector-General Dick, R.N.; Dr. Henry Fitzgibbon, Dublin; and several others. After the outgoing president (Dr. Macnaughton Jones) had relinquished the chair to Sir Thos. Crawford, now president, the annual report of the Council was read. The number of members on the roll had increased within the year from 358 to 459. The Council had to regret the loss by death of six—viz., Drs. Thompson (founder of the Association), Curtin, Eames, Staff Surgeon O'Sullivan, R.N., Dr. Sexton, and Deputy Surgeon-General Wolesley. Among the more important matters which had been and were still under the consideration of the Council, were the disabilities under which graduates laboured who held the higher qualifications of the Dublin Colleges. The hon. treasurer's report was very satisfactory, and showed a substantial balance to the credit of the Association. Professor

Digitized by Google

Alexander Macalister, M.D. (Trin. Coll., Dublin), F.R.S., was then nominated as president-elect. Cordial votes of thanks were accorded to Dr. Macnaughton Jones, who had so ably and zealously occupied the chair for two years, and to Dr. Daniell on his resigning the post of hon. metropolitan secretary, which he had filled since the foundation of the Association. In the evening the members dined together at the Holborn Restaurant.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Sutton-Coldfield Urban District.—Dr. Bostock Hill was appointed in May last to act as health officer for this newly incorporated borough. His report deals at length with the statistical returns, which show a birth-rate of 23·06 and a death-rate not exceeding 12·6 per 1000, the zymotic rate also being low—namely, 1·04. Indeed, in a population of 8630 no death occurred from typhoid fever, only 1 from diphtheria, and 2 from diarrhœa. The isolation hospital is maintained in a state of readiness, and by its aid much may be done towards a continuance of freedom from preventable diseases. Sewer extensions are much needed, and we note that some commencement of this work is in hand. At present there are no bye-laws, and in deciding as to their adoption the authority would do well to examine the annotated edition of the model code issued by Messrs. Knight and Co. The question of offensive trades, dairies, cowsheds, and milkshops, bakehouses, and overcrowding are either being dealt with or under immediate consideration. The prevailing meteorological conditions are discussed in the report in connexion with the health of the district.

Blackpool Urban District.—We have elsewhere referred to that portion of Dr. Welch's report which deals with the question of the isolation of infectious fevers. We here note the report generally. During 1886 the general death-rate on nearly 20,000 people was 18·9 per 1000, but deduction being made for forty-six deaths in visitors, the rate is reduced to 16·5. Infant death under one year has, during seven years, decreased from an average of 16·3 to 15·1 per cent. of registered births; but even the latter rate is needlessly high, especially for such a place as Blackpool. In connexion with the association of faulty sanitary circumstances with this death-rate, Dr. Welch explains that in one street five deaths from infantile diarrhœa have occurred during the last few years. They all took place on one side of the street, and the only difference which was noticeable as regards the houses, which were otherwise alike on both sides, was the fact that on the diarrhœa side of the street the back windows overlooked old-fashioned open ashpits, whereas on the other they faced a blank wall. That such structures, together with common privies elsewhere reported, should exist in a town taking its place as a health-giving resort constitutes a reproach which calls for removal. The town water service, otherwise wholesome, needs efficient filtration, and the systematic flushing of the mains is also periodically required. The need for improvement as to open space at the back of houses is likewise maintained. In Blackpool, it is evident that even the small minimum space required under the bye-laws is not always enforced. Should this continue, that undue aggregation of houses on area which has ruined the sanitary reputation of many a town will gradually assert itself. Dr. Page, of the Local Government Board, has recently visited Blackpool, and he has urged on the authority the need for substantial improvement in several respects, to which Dr. Welch also refers.

Shipley Urban District.—In this district the birth- and death-rates for 1886 were 24·8 and 13·3 per 1000 respectively, and whereas the average number of deaths from the seven principal zymotic diseases for the years 1879-85 was 23, the total was only 3 last year. Notification of infectious diseases is pretty general in the district, but, as Mr. Ellis points out, it comes so often at the wrong time. People notify so as to secure the aid of the sanitary officers for the purposes of disinfection at the close of an illness, whereas the primary object of notification requires that the information shall be supplied at the earliest possible date in the history of the case. Isolation was in certain cases of scarlet fever carried out by removal of the sick to the apartments provided for the authority, on a payment of 3*s.* a day, at the Sir Titus Salt Hospital. Mr. Ellis secures the personal attendance of his authority during an inspection of his district; this is a plan admirably calculated to ensure abatement of conditions injurious to health, and it is evident from the steady reduction in the rate of mortality which has been in progress ever since 1875, and this notwithstanding a growing population, that the sanitary interests of Shipley are held to be of importance. The saving of life on 17,000 people which must have followed a reduction from 23·5 per 1000 in 1875 to 13·3 per 1000 in 1886 is very great, and with it has gone a saving of much misery and unhappiness.

Torquay Urban District.—This district is about to be materially improved, since, under the Torquay Harbour and District Act, the harbour, with its still piece of water, is now in the hands of the sanitary authority, and can be kept free from the nuisance which follows on the accumulation of seaweed and of dead fish left by wasteful fishermen. The compulsory notification of infectious diseases has also been secured for the town, together with other sanitary powers, such as relate to obtaining from dairymen lists of their customers, and to the inspection of dairies outside the district. With but few exceptions, Mr. Karkeek has a satisfactory record to give for the year. In one instance grossly defective conditions of house-drains in a dwelling led to fatal typhoid fever almost immediately on the house being entered. Those who had formerly lived there appear to have become habituated to the evils; but, as often happens, a new-comer not accustomed to inhale drain air was smitten down at once. Nothing short of a house-to-house inspection, which lies at the root of efficient sanitary work, or, failing that, the registration of all sublet houses and their control by bye-laws, can deal with such cases. The death-rate on 25,000 was 16·48 per 1000, or, if visitors are excluded, 14·76 per 1000.

Holsworthy Rural District.—Mr. Linnington Ash gives the birth-rate and death-rate for this district as 30·8 and 17·5 per 1000 respectively; the zymotic rate being 1·7. About the end of the second quarter diphtheria made its appearance, and, in spite of every effort to induce parents to apprehend the danger and to take the proper precautions, the disease spread through the medium of school attendance. Although the school was closed, it caused four deaths, and also continued into the fourth quarter of the year. Measles and whooping-cough were also present during the year, and it is shown that the district finds itself hampered in dealing with infectious diseases by reason of the absence of any proper means for the isolation of first cases. In Holsworthy town the need for a proper water-supply is most pressing. For three months last year there was practically a water famine, and though the matter has been under notice again and again, it remains as yet quite undealt with. Indeed, no work for securing permanent sanitary improvements has been carried out during the past year, although in several respects they are much needed.

Exeter Urban District.—The Exeter Sanatorium contained 97 patients during 1886, scarlet fever affording 61, typhoid fever 18, and small-pox 14 cases. The death-rate was only 4·7 per cent. of admissions. As regards small-pox, it is stated that that which appeared at one time to threaten a severe epidemic was brought to an end by means of the isolation afforded. It further appears that although 230 cases of scarlet fever have been under treatment there between November 1st, 1877, and December 31st last, there has been no death from this disease since November, 1877.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5516 births and 3977 deaths were registered during the week ending March 19th. The annual death-rate in these towns, which had been equal to 21·3 and 21·6 per 1000 in the preceding two weeks, further rose last week to 22·4. During the first eleven weeks of the current quarter the death-rate in these towns averaged 21·9 per 1000, and was 2·1 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 13·9 in Birkenhead, 16·5 in Halifax, 17·2 in Brighton, and 17·8 in Ports-

Digitized by Google

mouth. The rates in the other towns ranged upwards to 28·6 in Newcastle-on-Tyne, 29·6 in Oldham, 33·1 in Bristol, and 33·2 in Manchester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had increased in the preceding five weeks from 340 to 412, further rose last week to 462; they included 213 from measles, 112 from whooping-cough, 45 from scarlet fever, 35 from diarrhœa, 32 from "fever" (principally enteric), 24 from diphtheria, and only 1 from small-pox. No death from any of these principal zymotic diseases was registered last week in Brighton or in Birkenhead; they caused, however, the highest death-rates in Bristol, Huddersfield, Oldham, and Sunderland. The greatest mortality from measles occurred in Leicester, Norwich, Bristol, Salford, Manchester, and Huddersfield; from whooping-cough in Bristol, Huddersfield, and Oldham; and from scarlet fever in Bristol. The 24 deaths from diphtheria in the twenty-eight towns included 13 in London, 2 in Portsmouth, 3 in Liverpool, and 3 in Oldham. Small-pox caused one death in Sunderland, but not one in London, and its outer ring, or in any of the twenty-six other large provincial towns. Only 3 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had been 466, 459, and 433 in the preceding three weeks, rose last week to 474, but were 67 below the corrected average. The causes of 119, or 3 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Derby, and Birkenhead. The largest proportions of uncertified deaths were registered in Halifax, Hull, Salford, Oldham, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 23·6 and 25·0 per 1000 in the preceding two weeks, further rose to 26·2 in the week ending March 19th; this rate exceeded by 3·8 the mean rate during the same period in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 15·8 in Dundee and 19·5 in Edinburgh, to 30·2 in Glasgow and 41·7 in Aberdeen. The 655 deaths in the eight towns last week showed a further increase of 30 upon the numbers in the preceding two weeks, and included 50 which were referred to measles, 28 to whooping-cough, 11 to diarrhœa, 9 to scarlet fever, 8 to "fever" (typhus, enteric, or simple), 6 to diphtheria, and one to small-pox; in all, 113 deaths resulted from these principal zymotic diseases, against 98 and 101 in the previous two weeks. These 113 deaths were equal to an annual rate of 4·5 per 1000, which exceeded by 1·9 the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of measles, which had been 27 and 43 in the preceding two weeks, further rose last week to 50, of which 35 occurred in Aberdeen and 14 in Glasgow. The 28 deaths from whooping-cough exceeded the number in the previous week by 3; 19 occurred in Glasgow and 4 in Aberdeen. The 9 fatal cases of scarlet fever, on the other hand, showed a further decline from recent weekly numbers; 6 were returned in Glasgow and 2 in Edinburgh. The 11 deaths attributed to diarrhœa corresponded with the number in each of the previous two weeks, and included 4 in Glasgow, 2 in Greenock, and 2 in Paisley. The 8 deaths referred to "fever" exceeded the number in any recent week; 4 occurred in Glasgow and 2 in Aberdeen. Of the 6 deaths from diphtheria, 3 were returned in Glasgow and 2 in Leith. The death classed to small-pox was said to be a fatal case of chicken-pox in Glasgow. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 142 and 135 in the preceding two weeks, rose last week to 152, but were 52 below the number returned in the corresponding week of last year. The causes of 69, or more than 10 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 28·1 and 31·3 per 1000 in the preceding two weeks, declined again to 29·3 in the week ending March 19th. During the first eleven weeks of the current quarter the death-rate in the city averaged 30·9 per 1000, the mean rate during the same period being but 20·7 in London and 21·3 in Edinburgh. The 198 deaths in Dublin last week showed a decline of 14 from the number in the previous week; they included 4 which were referred to "fever" (typhus, enteric, or simple), 2 to scarlet fever, 1 to diarrhœa, and not one either to small-pox, measles, diphtheria, or whooping-cough. Thus the deaths from these principal zymotic diseases, which had been 15 and 10 in the preceding two weeks, further declined last week to 7; they were equal to an annual rate of 1 per 1000, the rates from the same diseases being 2·2 in London and 1 in Edinburgh. The deaths from "fever," which had been 8, 5, and 5 in the previous three weeks, further declined last week to 4. The fatal cases of scarlet fever were 2, against 7 and 1 in the previous two weeks. The deaths of infants showed a marked decline from the numbers in recent weeks, and those of elderly persons were fewer than those in the previous week. Five inquest cases and 6 deaths from violence were registered; and 57, or nearly a third, of the deaths occurred in public institutions. The causes of 36, or more than 18 per cent., of the deaths registered during the week were not certified.

MORTALITY IN LARGE LANCASHIRE TOWNS IN 1886.

The twenty-eight large towns dealt with by the Registrar-General in his weekly return include seven Lancashire towns, which had in the middle of last year an aggregate population of more than a million and a half. Liverpool headed the list with a population of 586,320; while the smallest town was Preston, which had an estimated population of 101,340. The mean death-rate in these seven Lancashire towns during last year was equal to 24·4 per 1000, against 20·0, the mean rate in the whole of the twenty-one other large towns in the list, and against 19·9 in London. Thus in equal numbers living the mortality in the Lancashire towns last year was 120 to 100 in the other large towns, showing an excess of a fifth, or of 20 per cent. Striking as is the excess of the recent mortality in these Lancashire towns measured in this manner, the true excess, if due account be taken of the sex and age constitution of the population of these towns, is still greater. Duly corrected for this disturbing element, on the assumption that the sex and age distribution of the population of each of the towns is the same as that of England and Wales, the death-rates in these seven Lancashire towns last year were 24·0 in Salford, 25·3 in Oldham, 25·4 in Bolton, 26·1 in Liverpool, 27·8 in Blackburn, 29·4 in Manchester, and 31·4 in Preston. The rates in the twenty-one other large towns, corrected in a similar manner for sex and age inequalities, ranged from 17·6 in Brighton and 18·9 in Derby, to 24·5 in Portsmouth and Cardiff and 24·7 in Halifax. The rates, therefore, in six of the Lancashire towns exceeded those recorded in any of the other towns; while the rate in Salford (the lowest in any of these large Lancashire towns) was only exceeded in Portsmouth, Cardiff, and Halifax. The rates in the six Yorkshire towns stand out in favourable contrast with those of the seven Lancashire towns above referred to. It should be stated that recent death-rates in the Lancashire towns bear favourable comparison with the rates in past years, but they do not show a reduction at all commensurate with that which has been so marked in the death-rates of English urban populations generally. That the excess of mortality in the Lancashire towns is the result of defective sanitary condition may undoubtedly be inferred from the fact that the excess is as strongly marked in the rate from the principal zymotic diseases and in the rate of infant mortality as it is in the general rate from all causes. It may be noted, for instance, that the mean rate from "fever" (principally enteric) in the seven Lancashire towns was nearly twice as high as the mean rate in the twenty-one other large towns, while the death-rate from scarlet fever was more than twice as high. Few will now deny that, at any rate, the mortality both of enteric and of scarlet fever is clearly within the control which it is possible for good sanitary organisation to command.

MORTALITY IN AUSTRIAN CITIES.

From a return just issued in Vienna, it appears that Austria contains forty-nine towns, each of which in the middle of last year contained an estimated population exceeding 12,000 persons. Vienna heads the list with a population of 780,066, and four other cities have populations exceeding 100,000: Prague with 182,935, Trieste 155,197, Lemberg 117,902, and Graz 103,670. There are five towns with popu-

Digitized by Google

lations varying between 50,000 and 100,000; while the population of the remaining thirty-nine towns range between 12,000 and 50,000. According to this return, the death-rate per 1000 of the population during last year was 28·5 in Vienna, 39·0 in Prague, 39·8 in Trieste, 34·4 in Lemberg, and 30·4 in Graz. In the smaller towns still higher rates prevailed, and it is noteworthy that in only four of the forty-nine towns was the death-rate in 1886 below 25 per 1000; in thirteen it was between 25 and 30; in eighteen between 30 and 35; in eleven between 35 and 40; and in three towns the rate exceeded 40 per 1000. These strikingly high rates of mortality in the Austrian cities present a remarkable contrast with the rates that prevailed last year in English towns. In the twenty-eight large towns of England and Wales, with an average population many times greater than the average population of the Austrian towns, the death-rate last year ranged from 17·1 in Brighton and 18·2 in Derby, to 26·3 in Manchester and 28·9 in Preston. The range of mortality in the Austrian cities above referred to was between 21·4 and 48·1. This marked excess was in great measure due to the mortality of zymotic diseases, to which further reference will shortly be made.

THE SERVICES.

Deputy Surgeon-General Sir J. A. Hanbury, K.C.B., the Principal Medical Officer of the Home District, has been ordered to hold himself in readiness to proceed to the Mediterranean, for the purpose, we presume, of taking up the appointment of Principal Medical Officer at Gibraltar in succession to Surgeon-General Fraser, who will be placed on the retired list under the provisions of the age-clause of the Warrant. *The Times* correspondent at Rangoon states that the commissariat and medical arrangements for the police in Upper Burmah have been very defective, and that Mr. Crosthwaite has selected Surgeon-General Farrell, of the Indian Medical Service, to take charge of the medical arrangements.

WAR OFFICE.—Army Medical Staff: Surgeon-Major Francis Henry Welch to be Brigade Surgeon, vice John Henry Hunt, deceased. Dated Feb. 24th, 1887.

ADMIRALTY.—The following appointments have been made: Surgeon G. H. Meaden, to the *Seaflower;* Surgeon E. A. Spiller, to the *Martin;* Surgeon G. E. Kennedy, to the *Nautilus;* Surgeon J. E. Webb, to the *Pilot;* Surgeon J. F. Bate, to the *Sealark;* Surgeon J. Andrews, to the *Liberty* (all to date from the 25th inst.); and Surgeon R. Hickson, to the *Lion.*

"Audi alteram partem."

TREATMENT OF PLACENTA PRÆVIA.

To the Editors of THE LANCET.

SIRS,—I have only just read your complimentary remarks of March 5th on my recommendations in treating placenta prævia, and the letter of Dr. Jas. Murphy on your approval of them. There is one remark of yours I should like permission to correct, when you say, "though some facts in the pathology of placenta prævia (such as the arrest of hæmorrhage after turning and before extraction) were unknown to him and his contemporaries." On page 27 of my "Combined External and Internal Version" (1864) I say: "I believe that in nearly every case the bleeding will be found to be controlled by the drawing down the child after version so as to fill up the os uteri. I have never found any bleeding after this point has been gained." Again, page 28: "Should there be reason to fear hæmorrhage was going on internally, then the delivery might be hastened; but I have in all the cases narrowly watched for any externally or internally without having met with it. Such a state is of course possible, but I think it must be rare," &c.

With regard to Dr. Murphy's letter, I may say that it affords me great pleasure to be in happy rivalry with plans that have reduced the former mortalities to so low a point. For my own part, I do not wish anything I have suggested to take a position other than it deserves; the saving of life is too earnest a thing to stand behind personal interest. I may, however, be permitted to point out that the treatment of cases of placenta prævia clinically may be divided into two classes: one where we are suddenly called without previous acquaintance with the case, without any means at command but our hands; the other where, having seen the patient beforehand, we can calmly set our plans to bear on the treatment. In the former, particularly, the plan I have suggested gives us the command of the position such as none other can give. In those cases where we have time the importance of terminating the pregnancy cannot be overrated; it is that which I have for years inculcated in my lectures, and I have no doubt others have in theirs; but in this I make no claim to originality, for it is to Dr. Greenhalgh we are indebted for the first definite laying down of what Dr. Murphy in his letter wishes to enunciate as a ninth great proposition. In 1864, in a paper read before the Obstetrical Society of London, Dr. Greenhalgh said that "in any given case of hæmorrhage due to placenta prævia occurring after seven and a half months of utero-gestation, when the child is viable, it is expedient, both for the safety of the mother and child, to expedite labour—unless the condition of the exhaustion be such as to preclude this step; and if so, then as soon as possible after she has recovered from the shock." This is virtually the same as Dr. Murphy enunciates as his ninth proposition. In the discussion on that paper my plan of turning is compared with that of the older internal mode, to the great advantage of the "combined." In that discussion I said that I "quite agreed with Dr. Greenhalgh as to the necessity of inducing labour in placenta prævia as soon as arrangements could be made, which I believed to be the plan adopted by all who saw much midwifery in that city; it was the practice I had always adopted" (*op. cit.*), and in my paper read in 1863 at the Obstetrical Society, and in the little work "Combined External and Internal Turning," of the same year as Dr. Greenhalgh's paper, I allude to the advantage also given us in dilating the os with Barnes' bags and separating the placenta around the os. "The value of these bags is very great, and they give us the power of operating at a date far earlier than we ever possessed before." But the separation of the placenta by the finger in placenta prævia is not always without severe loss. I have had several cases where on peeling off the placenta the hæmorrhage was so violent that had I not been able to use the bipolar method serious results would almost certainly have occurred. Doubtless, the mortality from placenta prævia has been latterly much lessened by the rule laid down by Dr. Greenhalgh of early termination of the pregnancy, by those who have followed it; but it still needs to be more generally known and practised, and Dr. Murphy's emphatic endorsement will assuredly do much good.

I am, Sirs, yours truly,

George-st., Hanover-sq., March 21st, 1887. J. BRAXTON HICKS.

THE ROYAL UNIVERSITY AND UNION HOSPITALS.

To the Editors of THE LANCET.

SIRS,—I have received a communication from the Privy Council in which marked prominence is given to the fact that the utilisation of union hospitals is still under the consideration of the General Council. One member of that body fell into the strange error of stating that these hospitals lacked material for teaching. The Irish Local Government Report for 1886 will show that 52,000 were admitted in 1885 in sickness from the outside. These were all cases that were of course too sick to be treated in the dispensaries. They were admitted under an Act which opened up these hospitals to the general public, and of whose existence our critics seem to be unaware. That report will further show by its table of the causes of deaths that at least 24,000 sick paupers were likewise entitled to be placed among the *bonâ-fide* clinical material. The further pretence of the Royal University that they could not exercise proper supervision over such hospitals is met by their own action in recognising other hospitals over which they could not exercise it, and in their not exercising it where they could do so. The time is not far distant when self-respecting provincials will be able to defend their own interests.

I am, Sirs, yours truly,

Cashel, March 15th, 1887. THOMAS LAFFAN.

INEQUALITY OF THE PUPILS IN TUBERCULAR MENINGITIS.

To the Editors of THE LANCET.

SIRS,—My friend Mr. Buxton has rather mistaken the origin and object of my letter on "Inequality of the Pupils in Various Diseases." It was written because I noticed that Dr. Pasternatski, in writing on this subject, and enumerating several diseases where this symptom existed, did not mention tubercular meningitis. Now, as my experience is that it is often present where tubercle of the cerebral membranes exists, I was desirous of knowing if this was an accidental omission, or that Dr. Pasternatski had not observed the symptom in tubercular meningitis. It did seem to me more than a coincidence that my fatal cases had unequal pupils to a very marked degree (I have copious notes of a very interesting case in a boy of nine, where one pupil was widely dilated and the other contracted to a pin's point, both insensible), while in the cases of recovery it did not exist; and it still appears to me reasonable that the pressure on the brain, whether caused directly by tubercle or by fluid the result of tubercle, should produce graver symptoms when that pressure is all on one side, and not shared between the two cerebral hemispheres; and thus unequal pupils may become an important and valuable symptom affecting the prognosis, although of course not necessarily excluding the diagnosis; and Mr. Buxton has not shown that there is not a tendency—and I think there is—for the fluid to gravitate more or less on one side in this disease. I did not examine the fundi; the pupils in every fatal case were insensible.

I am, Sirs, yours truly,

March 22nd, 1887. FREDK. H. ALDERSON, M.D.

ERYSIPELAS AFTER VACCINATION.

To the Editors of THE LANCET.

SIRS,—The article on the above subject in your last issue induces me to draw attention to a factor of importance in the causation of erysipelas—i.e., hereditary predisposition. This was brought forcibly under my notice a few years ago, while holding the post of public vaccinator to a district in Yorkshire. I had a severe case of spreading erysipelas following vaccination in a child nine months old, who eventually recovered after a long illness. There was nothing either in the history of the inserted lymph, or, as far as I could judge, after careful inspection and inquiry, in the sanitary surroundings of the patient, to account for the disease, but there was a decided family history of erysipelas, both parents having suffered from it, the father being peculiarly prone to attacks of the facial variety. All other explanations failing, I attributed the occurrence to the depressing influences of teething and an inherited predisposition to the development of erysipelas, the vaccination wounds merely affording an inlet to the active elements of the disease, which under different circumstances might have been innocuous. The case made a lasting impression on my mind, and is certainly suggestive in view of similar occurrences.

I am, Sirs, yours faithfully,

JAMES TURTON, M.R.C.S.,
Late Public Vaccinator, Dewsbury Union.

Brighton, March 20th, 1887.

"A CASE FOR INQUIRY": A DISCLAIMER.

To the Editors of THE LANCET.

SIRS,—THE LANCET of the 12th ult. has only just come into my hands, and I am very much astonished to find in your annotations a paragraph which, unless the matter is cleared up, may be considered to refer to me. I find on looking at the Medical Directory for 1884 that I am the only T. Young in the whole of the United Kingdom possessing the qualifications mentioned. I have been unable as yet to procure copies of the *Illustrated London News* for the dates to which your paragraph refers; but whatever the matter may be, I most emphatically disavow any knowledge of it, inasmuch as I neither know nor have ever had any communication with Mr. Alabone. I assure you that both advertising and assumption of titles which are not legal have as little of my sympathy as of yours. I feel sure that, with your usual justice and impartiality, you will allow me in your next issue to disclaim any connexion between the "Dr. T. Young" mentioned in your issue of the 12th ult. and myself. I am, Sirs, yours faithfully,

THOMAS BRETT YOUNG, L.R.C.P., L.R.C.S. Edin.

The Laurels, Hales Owen, near Birmingham, March 22nd, 1887.

*** We gladly insert our correspondent's letter.—ED. L.

MANCHESTER.

(*From our own Correspondent.*)

HOSPITALS AND PROVIDENT DISPENSARIES.

IN THE LANCET of the 19th inst. is an article on Co-operation of Hospitals and Provident Dispensaries, pointing out the importance of this subject on the work of the committee which is now considering how best in London to organise medical attendance on the poor and prevent indiscriminate giving of free medical relief. The committee might gain some valuable information by applying to the proper quarter here. For many years the provident dispensary has worked with the Royal Infirmary and other medical charities, with the object of preventing abuse of the latter. Inquiries are made into the circumstances of all patients applying for aid, and after having given what assistance or help may be needed at the first time of coming to hospital, they are referred to the provident dispensaries, if their means are found to be such as to enable them to pay the scale of charges fixed by them. By this means the out-patient departments especially are kept from being overcrowded, and those who are proper objects for the work of the charities receive more attention than if the numbers were swelled to an almost unmanageable extent.

ST. MARY'S HOSPITAL.

At the late annual meeting of St. Mary's Hospital the balance-sheet showed an unsatisfactory condition, the expenditure in the past year having exceeded the income by £348. A most important matter was decisively announced—i.e., the attempt to raise a fund for building a new hospital. Already subscriptions to the amount of £10,000 have been promised, and important help has been promised by Madame Marie Roze, who will give a concert in aid of the movement. Many years ago Jenny Lind, then in the height of her fame, gave a concert on behalf of the Royal Infirmary, the proceeds from which went largely towards building a new wing.

THE SOUTHERN HOSPITAL,

which in a quiet unobtrusive manner does a good work on the south side of the city amongst women and children, is about to extend the sphere of its usefulness by adding a lying-in department to its present operations. Seeing that we are practically without a lying-in hospital, the effort is one worthy of support.

THE ROYAL INFIRMARY

has recently made an attempt to obtain funds from a rather unusual source, by applying to the various Local Boards for a contribution out of the rates, and in several instances the application has met with success. An announcement made at a late meeting of the Infirmary Board that the Fever Hospital was about to be extended, at a cost of £3000, has caused some correspondence in the daily press from some who object to all the infectious disease in Manchester and neighbourhood being taken to one spot, and from others who dispute the right of the Infirmary Board to expend its funds at all on a matter which it is the duty of the health authorities to attend to. The neighbouring borough of Salford has just disposed of its Fever Hospital, to the London and North-Western Railway, for upwards of £20,000, so that the Corporation will have to make fresh arrangements for the isolation of their infectious disease.

FEVER HOSPITAL FOR BRADFORD.

The Town Council of Bradford, in the adjoining county of Yorkshire, have just purchased the Fever Hospital there from the trustees of the hospital for the sum of £10,000. As a result of the action taken by the Sanitary Association, the City Council will for the future publish its Health Committee's report annually, instead of biennially, as hitherto. It has also been successful in obtaining the use of the playgrounds

Digitized by Google

of various of the School Boards for the use of children in crowded districts to play in after school hours, and it is now engaged in stirring up the Corporation authorities about their building bye-laws, which have long been in an unsatisfactory condition.

THE VICTORIA UNIVERSITY.

As a result of the important and influential deputation that waited on the Chancellor of the Exchequer, asking for a grant from Imperial funds towards the expenses of the Victoria University, it is announced that £2000 per annum will be granted. The amount asked for was £2500 a year. The number of students presenting themselves for the University Examination shows a satisfactory increase. At the present and approaching examinations upwards of seventy students from Owens College alone have entered for the preliminary scientific and various medical examinations. It has been decided that the testimonial to Sir H. Roscoe, to commemorate his long connexion with the College, shall consist of a portrait, to be presented to himself, and, if enough money is available, the establishment of a scholarship, to be named after him.

The Hospital Sunday and Saturday collections have not, as was hoped, shown any increase on last year's amount. The sum collected amounts to only £7250. A few additional payments yet to come in may possibly raise it to that of last year's collection.

March 22nd.

EDINBURGH.

(From our own Correspondent.)

SCARLATINA AND MILK.

AT the last meeting of the Public Health Committee of the Town Council a report was submitted by Dr. Littlejohn, the medical officer of health for the city, detailing the results of his investigations into the cause of the recent epidemic of scarlatina in the north-west quarter of the town. The inquiry was specially directed towards ascertaining whether there were any causal relation between special sources of the milk-supply and the peculiar localisation of the outbreak. The results conclusively show that such is the case, the affected district being for the most part supplied from a source proved to have been contaminated shortly before the commencement of the epidemic. The farm thus singled out contributes 120 gallons daily to the milk-supply of the city; the milk is at present of good quality and in all other respects quite unobjectionable, but there is little doubt that eight weeks ago it was each day transmitting infective material from the farm, where fever was then present, to the very parts of the city since so alarmingly visited by the disease. These facts curiously emphasise the recommendations contained in an annotation on "The Use of Uncooked Milk" in last week's LANCET. The precaution of boiling for five minutes the whole of the milk supplied to each household has been largely carried out in Edinburgh since Dr. Foulis' letter on the subject appeared in the local papers some weeks ago. It has been questioned in some quarters whether this procedure is an absolutely reliable method of disinfecting milk, regard being had to the peculiar physical constitution of that menstruum in relation to the transmission of heat. The general impression, however, is that this is a most valuable precaution, and as such it has been widely recommended to and adopted by the intelligent classes of the population. Dr. Littlejohn's investigations are in the meantime actively continued, and an extra staff of subordinates is placed at his disposal for the purpose. In the City Fever Hospital there are at present 199 patients suffering from scarlatina.

THE PROPOSED FEVER CONVALESCENT HOME.

A question has been from time to time under the consideration of the Public Health Committee as to the propriety of establishing a convalescent home for patients discharged from the City Fever Hospital. A moot point was the legality of applying public funds to this purpose. This has been submitted for counsel's opinion. The legal adviser of the board regards such an addition as simply an adjunct or necessary appendage of a fever hospital; and, as such, he holds that the local authority have full powers for establishing a convalescent home in connexion with the hospital. They are under no statutory obligation to apply donations from grateful patients of the hospital in reducing the public health rates, hence such funds might be expended in defraying the expenses of the proposed institution.

EDINBURGH UNIVERSITY COURT

The Court met last Monday and approved the arrangements already reported, by which the site for the completion of the New Medical Buildings is to be acquired and the buildings erected. They also confirmed the recommendation of the Senatus Academicus granting leave of absence to Prof. William Rutherford for six months on account of health, approving also the arrangements made by which Prof. Caton of Liverpool will conduct the professional examinations in physiology in April and July of this year. With reference to a letter from Mr. Ashdown, M.B., which was under consideration, the Court were of opinion that his character had been completely vindicated by Prof. Rutherford's apology to him, and that it was unnecessary for the Court to take any steps for that purpose. Mr. Joseph Bell having ceased to lecture on clinical surgery, the removal of his name from the list of recognised lecturers was authorised.

THE CHAIR OF PHYSIOLOGY.

A somewhat premature notice of the appointment of Professor Haycraft, of Birmingham, to the post of substitute-Professor of Physiology in Edinburgh University, during Professor Rutherford's leave of absence, has appeared in one of your contemporaries. As a matter of fact, such an arrangement is reported to have been made privately between Professors Rutherford and Haycraft, and is to be shortly submitted for the approval of the Senatus Academicus.

MEDICO-CHIRURGICAL SOCIETY.

At the last meeting of the Society Professor T. R. Fraser read a valuable paper upon the Dyspnœa of Bronchitis and Bronchial Asthma, and detailed important clinical and experimental results obtained from the administration of nitrites in such cases.

THE ARTIFICIAL CULTURE OF FISH.

Mr. J. T. Cunningham, B.A., Superintendent of the Granton Marine Station, has communicated a paper on the artificial culture of fish to the Association of Science and Art. Of particular interest was his demonstration of the Macdonald jar, a recent invention employed by the American Commission for incubating ova. The dead eggs are removed automatically, and in consequence a much larger percentage come to perfection than when this is not the case. Each jar will accommodate about sixty thousand eggs.

Edinburgh, March 22nd.

PARIS.

(From our own Correspondent.)

THE NEW "SPECIFIC" FOR DIABETES.

DR. MARTINEAU gives full details in the last number of the *Annales Medico-Chirurgicales* of the treatment advised by him in diabetes. It was in consultation with the late Professor Rouget that he learned the formula which he now publishes with so much confidence. The patient in question had been the subject of diabetes for some years, and was suffering at the time from cerebral hæmorrhage. Dr. Rouget proposed that they should not modify his diet in any way beyond restricting in a slight degree the use of farinaceous food, fruits, and sugar, and that he should drink during meals and in the intervals of thirst arsenicated lithia water, prepared as follows: In the upper part of a Briet apparatus of 1 litre for making aerated water were to be introduced 20 centigrammes of carbonate of lithia, and a tablespoonful of the following solution: arseniate of soda, 20 centigrammes; distilled water, 500 grammes. This water to be drunk at meals mixed with wine, and the contents of the recipient to last for three meals. Before commencing the treatment the urine was found to contain 60 grammes per litre of sugar, being 212 grammes for the quantity voided in the twenty-four hours. Three weeks later, on Oct. 12th, 2 litres, instead of 3½, represented the daily secretion of urine, and the quantity of sugar 20 grammes per litre. On Oct. 29th there were 1½ litre of urine, and the amount of sugar 11 grammes

Digitized by Google

per litre. On November 14th the proportions had fallen to 1 litre of urine containing 4 grammes of sugar. On December 1st no sugar could be detected, and the daily average of the urine was 1 litre. The patient died four years later of uræmia caused by renal disease, and up to the time of his death no sugar had ever been found in the urine. Dr. Martineau gives two other cases in illustration, in which the treatment has kept the glycosuria in abeyance for six and five years respectively. In a third instance no sugar has been seen for six months. In all the patients with whom the treatment was successful there were, says Dr. Martineau, arthritic symptoms, either in the form of biliary or renal lithiasis, of articular manifestations, or of cutaneous eruptions. In the only three cases of failure there was no arthritism, but herpetic symptoms existed in the form of "nervovism" and skin eruptions. The disappearance of sugar from the urine is attributed by Dr. Martineau to the action of the lithia upon the glycogenic matter, which it helps to transform into glucose, and thence into carbonic acid and water. It is the presence of lithia that also explains the action of those natural mineral waters which are useful in diabetes. Taking for granted that the results are as stated by Dr. Martineau, it is somewhat remarkable that he should fall into therapeutic superstition, when there is a much more adequate physiological explanation. In all his successful cases the quantity of drink was restricted to a quart during three meals, whereas in the unsuccessful case, which is given for the sake of comparison, the patient drank three litres and voided an equal quantity of urine in the twenty-four hours. The late Dr. Hyde Salter found abstinence from liquids at meal-times the most useful of all treatment for asthma, and obstructed respiration is given by Pavy as a cause of diabetes, Brunton allowing that it is produced by deficient oxidation, which comes to the same thing. There is a group of allied affections characterised by the retention of the products of imperfect oxidation, and by functional disturbances of different kinds resulting therefrom, the cause and effect having a reciprocal action. Gout and nervous depression, obesity and imperfect respiration, are familiar examples. In these cases, as in rheumatism and other morbid conditions of the same kind, everything that promotes oxidation and excretion is of capital importance. Abstinence from alcohol and the use of the Turkish bath are valuable means to this end, but total abstinence from alcohol, with a strict limitation of fluids, is the most potent of all. Unfortunately it is extremely difficult, most especially in diabetes, to carry out such restrictions. If, however, lithia as administered by Dr. Martineau does enable diabetics to abstain from liquids, he may be congratulated upon having made a valuable contribution to practical medicine.

THE HEALTH OF PARIS.

The *Bulletin Hebdomadaire de Statistique Municipale* records thirty-seven deaths from typhoid fever, being a slight decrease upon the preceding week. But the admissions into the hospitals are more numerous than ever—ninety-six as against seventy-seven; and there is even reason to anticipate a continuance of the epidemic. The mortality from small-pox has increased from two to ten deaths, and the admissions into the hospitals from thirty to forty-one. This sudden outbreak is attributed to the arrival in Paris of a large number of unvaccinated workmen for the building of the forthcoming Exhibition, and Dr. Du Mesnil has laid before the Board of Health a project of compulsory vaccination. In an article in the *Bulletin Médical* he reminds his readers that the epidemic of 1870-71, which caused a mortality of more than 5000 persons, coincided with the arrival in Paris of the soldiers of the Garde Mobile, a large number being from Brittany, where vaccination is extremely insufficient. The commercial stagnation of the last few years had caused the departure of many of the workmen, and this has been followed by a great diminution in the number of deaths from small-pox. But the number of admissions to the hospitals has lately increased, and the authorities have been obliged to reopen special wards. Professor Proust, in his report on the subject, agrees with Dr. du Mesnil, and urges the authorities to proceed to the compulsory vaccination and revaccination of all workmen coming to Paris for employment upon the Exhibition.

PROVINCIAL EPIDEMICS.

An inquiry has been made into the sanitary condition of the Marine Barracks at Lorient, where typhoid is endemic, and causes annually from forty to fifty deaths amongst the troops. It has been found that the water is regularly contaminated with human excreta whenever there is rain, the conduits in masonry passing under fields and gardens so manured. At Brest an epidemic recently broke out in the training ship *Le Borda*. An analysis of the water showed the presence of the characteristic bacillus. There are also serious epidemics at the present moment in the Marine Barracks at Cherbourg, and amongst the soldiers of the 50th Regiment at Perigueux. The Governesses' Normal School of the Loire-Inférieure has been closed on the same account.

Paris, March 22nd.

NAPLES.

(From a Correspondent.)

ITALIANS complain that theirs is a severely-visited country—not in the sense of its being overrun with foreigners, for to these it owes a fifth of its annual revenue, but in the sense of its continual subjection to visitations atmospheric and telluric. What with floods, earthquakes, and cholera explosions, the last five years in Italy have certainly been prolific of death and disaster beyond the usual portion of humanity. In 1882 the inundations in the Venetian territory and in the Two Sicilies left a fearful tale of ruin and misery. In 1883 the earthquakes at Casamicciola reduced a garden-island of the Mediterranean into a sombre, silent waste. In 1884 the most terrible outbreak of cholera within living memory swept the Italian seaboard from the Riviera to the Messina Straits, alighting with such force on Naples as, in one night, to strike down two thousand of the inhabitants, of whom one thousand died in a few hours. In the following two years the scourge extended to Sicily, while continuing its ravages among the littoral and river-side population of the peninsula; and now another telluric storm has raged along the Riviera Levante e Ponente, overthrowing towns, engulfing their inhabitants, and leaving a moral and material ruin behind it which years will not repair. Well may the *Popolo Romano* say: "If calamities are so many trials to strengthen the character, we Italians bid fair to become the strongest people in the world."

To do her justice, Italy is so far profiting by this probation as to be improving her position in view of a recurrence of such disasters. Floods, so largely due to the destruction of forests by felling, she is preparing to obviate by stringent regulations for replanting the denuded mountain-sides; cholera visitations, invited by insanitary conditions, she will in future keep at bay by vigilant hygienic surveillance; while so far as seismology can forewarn against telluric storms, and suggest opportune precaution or provision, she is to aid experts in that infant science, like the Padre Denza and Michele di Rossi, with enhanced means of research and internuncial communication. As to the sanitary side of her endeavours, here in Naples we have ample evidence of her sincerity and energy, the water-supply being now the finest in the peninsula—inferior, if at all, to that of Rome, and inferior in abundance only. "Out of the nettle Danger to pluck the flower Safety" should be her watchword for half a century to come—far more justly, indeed, than the "si vis pacem, para bellum," which, in practice, is crushing her, like other continental powers, under the weight of "bloated armaments."

The resources of the Spedale della Trinità are severely taxed to accommodate and treat the wounded survivors of the Dogali massacre whom the troopship *San Gottardo* deposited here on Feb. 22nd. Certainly the literature of surgery will be conspicuously enriched by the official report of the Trinità staff when it sees the light; gunshot wounds, incised wounds, and lacero-contusions of every variety, and sometimes all three on one and the same soldier figuring amongst its most prominent details. Meanwhile the courage of the medical officers who died as combatants on that tragic field has evoked from all Italy the proudest eulogy. In Rome a special meeting of the Royal Academy of Medicine was convened to express the feelings of the profession on the subject, and in its president, the Hon. Guido Baccelli, no better spokesman for the occasion could have been found. At the close the following order of the day was carried by acclamation: "The Royal Academy of Medicine at Rome draws the attention of all Italy's scientific bodies to the

Digitized by Google

heroic conduct on the battlefield of Dolgali of the army surgeons, Captain Nicola Gasparri and Angelo Ferretti."

Cardiac neuroses due to syphilis are engaging particular attention just now, especially in the clinic of Professor Semmola. The venereal taint is a well-known factor in organic disease of the heart; functional disturbance of that organ, due to the same cause, has been much less carefully worked out. More than fifty such cases have come under Professor Semmola's cognisance. Weak systole, intermittence, di-systole, were common to all; while the respiratory process, though its apparatus was quite sound, became distressed on mounting stairs or in hurried walking. Hitherto physicians have diagnosed such cases as due to nervous exhaustion, and have prescribed the usual remedies—tonics, rest, country or sea air, and so forth. But after weeks or months of such treatment the symptoms remained as before, or were often aggravated. "The use of mercury, however," says Professor Semmola, "in the form of hypodermic injections of corrosive sublimate, and the use of iodide of potassium *viâ* the stomach, produced in all these cases progressive amelioration, and finally a total disappearance of the functional derangement, while the improvement of the whole system was most marked." Dr. Vincenzo Vitoni, in an able contribution to the discussion, says: "Functional derangements of the heart, unaccompanied by the physical signs of endocarditis, aortitis, and so forth, when they occur in patients affected for some time by constitutional syphilis, and in whom hygienic conditions and the cure of symptoms have failed to induce a return to normal cardiac action, justify the physician in first prescribing iodide of potassium in progressive doses, and then, after fifteen or twenty days, in trying mercurials with the caution that characterises good clinical practice. It were idle to theorise on the *modus operandi* of syphilis in causing functional derangements of the heart—due, as they might be, to arteritis of the coronaries, to primary nutritive irritations of the myocardium, to incipient arterio-sclerosis, or to a general undetermined dyscrasic condition of a clinical type. What emerges clearly from the facts is this, that we have to deal with a pathological state of the heart quite amenable to iodide of potassium and to mercury." Professor Semmola does not share the belief, any more than does Dr. Vitoni, that mercury is always contra-indicated in cardiac affections. Caution, after due diagnostic investigation, is all they plead for. The whole subject is well discussed in *La Terapia Moderna*, a monthly organ of the Neapolitan school, which began its career, with good augury, on Jan. 1st.

Naples, March 6th.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AT an extraordinary meeting of the Council held on Thursday, the 24th inst., the minutes of the last ordinary meeting were read and confirmed. The following resolution was carried *nem. con.*: "That the Council see no cause to alter their decision regarding the admission of the Apothecaries' Society to the Conjoint Scheme." A letter was read from Sir H. Pitman, forwarding a copy of the resolution passed by the Royal College of Physicians on the same subject.

Two memorials, signed by several thousand persons, were submitted to the Council, in opposition to a memorial laid before the Council advocating the endowment of an institution for the promotion of physiological and pathological research.

A letter was read from the Councils of University and King's Colleges, inviting the College to confer with representatives of those Councils and of the Royal College of Physicians of London on the subject of a joint application to the Crown on behalf of the four institutions for powers to grant degrees in Medicine and Surgery. This letter was referred to the Committee of Delegates on the subject of granting degrees in Medicine and Surgery.

The following motion by Mr. Croft was lost, four voting in its favour and twelve against: "That before each election to the Court of Examiners the lists of Fellows who are candidates shall be considered by a small committee, to be appointed annually by the Council, who shall have power to recommend to the Council one or more of the candidates for each vacancy."

MEDICAL NOTES IN PARLIAMENT.

The Pharmacy Acts Amendment Bill.

IN the House of Lords, on the 18th inst., this Bill was passed through Committee, with a few verbal amendments.

On the 22nd inst. the report of amendments was brought up and agreed to, and on Thursday, the 24th, the Bill was read a third time and passed.

Vaccination and Disease.

In the House of Commons on the 18th inst. Mr. Ritchie, in reply to Mr. M'Arthur, stated that revised instructions have been issued to public vaccinators with a view to minimise the risks of vaccination. The order for the careful examination of vaccinifers as to the existence of skin diseases, and particularly of hereditary syphilis, was contained in the old instructions. The Local Government Board has no evidence of syphilis having been communicated by vaccination from a child not itself presenting signs of syphilis.

Anthrax.

On the 21st inst., in reply to Sir J. Swinburne, Mr. W. H. Smith, in the absence of Lord J. Manners, stated that an inquiry in reference to the recent outbreaks of anthrax is now being conducted by the officers of the Agricultural Department. There is no reason, however, to believe that the disease has been more prevalent during the last six months than previously. The Anthrax Order of September last imposes on the owners of animals the obligation to give notice of the disease, and on the inspectors the duty of making returns weekly; hence public attention has been called to outbreaks which otherwise would have escaped notice. None of the outbreaks have been traced to railway trucks in which foreign hides had been previously carried.

On the 22nd inst., in reply to Mr. Tollemache, Mr. W. H. Smith stated that the Government do not propose to treat anthrax in the same manner as pleuro-pneumonia, as they are advised that the two diseases are of a totally different character. Slaughter in anthrax would in most cases be impracticable, as animals are usually found dead without any warning, or die very quickly after the symptoms become apparent. Further, as the disease does not spread by association of diseased with healthy animals, as is the case with pleuro-pneumonia, slaughter and compensation would only be for the benefit of the owner, and not for the community.—In reply to Sir J. Swinburne, Mr. W. H. Smith said that the recent outbreak of anthrax in Cheshire has apparently been confined to one farm, and chiefly affected swine, of which thirty-four are reported to have died, and also three sheep. No cases have been reported since March 19th. Immediately the disease was recognised the local authority took action under the Anthrax Order and prevented the movement of animals from the farm. An inspector of the Privy Council has visited the farm, and from his report it does not appear that there is anything remarkable in the outbreak of anthrax, which disease, it is said, occurs every year on this farm, and is accounted for by the existence of insanitary conditions which are most favourable for the development of the disease.

The Alleged Neglect at Guy's Hospital.

On the 21st inst. in reply to Mr. W. Corbet, Mr. Matthews said that he had been informed by the medical superintendent of Guy's Hospital that the facts of Stack's case are as follows: Stack was brought to the hospital at 7 P.M. on Monday, and was found to be suffering from a simple fracture of the small bone of his leg. He was taken into the accident ward for the night and received immediate attendance, and, as is usual in the case of similar injuries, the limb was temporarily placed in sandbags, and in the course of a few hours, between 11 and 12, the limb was put up permanently in plaster-of-Paris bandages. Stack was discharged on the following day, with a pair of crutches supplied at the expense of the hospital, and without any charge to Stack or his relatives. When Stack came to the hospital every bed in the ward was occupied, but one of the occupants, who was leaving the next morning, was placed on a stretcher, and thus made room for Stack. The hospital authorities seemed to have done all that was proper on this occasion.

The Planting of Cinchona.

In reply to Mr. Henniker Heaton, Sir J. Gorst said that one of the objects, but not the only one, of planting cinchona by the Madras Government was for the purpose of obtaining a febrifuge for the native classes. Government bark is advertised for sale in London, and comes to England for the manufacture of quinine. Government gets quinine for its medical departments at wholesale prices, and makes the "red bark" into an effective febrifuge cheap enough to be within the reach of all classes.

Pleuro-pneumonia.

In reply to Sir J. Swinburne, Mr. A. J. Balfour stated that Clause 6 of the Contagious Diseases (Animals) Amendment Act gives the Privy Council authority to make orders giving large powers to local authorities for the slaughter of animals which may have been in the same shed or field as diseased animals, and that the question as to how far the provisions of this clause can be enforced with the least inconvenience and expense is at present engaging the attention of the Privy Council Veterinary Department.—In reply to Mr. O'Doherty, Mr. A. J. Balfour stated that the regulations for the shipment of cattle are as carefully devised as possible. They are identical in England and Ireland, and are the same for cross Channels steamers as for those carrying cattle to Great Britain from other countries. The shipment of animals is superintended by officers of the Veterinary Department, who do all in their power to prevent any cruelty or infringement of the regulations, and he was afraid that no further action on the part of the department seems practicable.

Court-house Accommodation.

On Thursday, in reply to Sir J. Pearse, who asked if, in view of the unsatisfactory condition of the accommodation afforded to prisoners awaiting trial in many of the Court-houses in England and Wales, the Government would institute an investigation into the matter, Mr. Matthews said he was informed the accommodation was satisfactory, but in order to allay public anxiety on the subject an inquiry would be made.

Obituary.

ROBERT EDMUND CARRINGTON, M.D. LOND, F.R.C.P.

DR. R. E. CARRINGTON, whose sad death we announced last week at the early age of thirty-three years, was the second son of F. G. Carrington, Esq., for many years editor and one of the proprietors of the *Gloucestershire Chronicle*, and grandson of N. T. Carrington, Esq., a well-known Devonshire poet. He was educated at the King's School, Gloucester, where he took a scholarship, and then became a pupil at the Gloucester Infirmary, where he remained for a year, and entered at Guy's Hospital in 1870, taking a second prize in Arts on entrance. His student career was remarkably brilliant, for he obtained the silver medal in botany at the Apothecaries' Hall in 1872, and at the Preliminary Scientific Examination in the same year he was placed first (with the exhibition) in both chemistry and zoology, and took Honours also in botany. In 1874 he passed the Intermediate M.B. Examination, and was awarded the exhibition and gold medal in chemistry and materia medica, and placed second in physiology. In 1875 he became a member of the Royal College of Surgeons, and in the next year filled the offices of house-surgeon and resident obstetrician at Guy's Hospital. He was then appointed demonstrator of anatomy, and taught well and assiduously in this post for more than five years. He was a most painstaking and methodical teacher, and his accuracy of detail is well shown in a Manual of Dissections which he published, and which is the only text-book showing the student how questions on given dissections should be answered. On this account it became very popular with candidates for the higher anatomical examinations. During his demonstratorship he suffered from a severe attack of typhoid fever, and it is questionable whether he ever really regained his former robust health. In 1878 he passed his M.B. Examination, obtaining the second place and a gold medal in medicine, with Honours in forensic and obstetric medicine. In 1879 he became an M.D. Lond., and a Member of the Royal College of Physicians, obtaining the Fellowship last year. Whilst still a demonstrator of anatomy at Guy's Hospital, he was elected in 1880 a visiting physician to the Seamen's Hospital, and he here showed the excellence of his training at Guy's as a most accurate clinical observer and a good pathologist. He contributed many articles to Guy's Hospital Reports and to the Pathological Society's Transactions, and was a regular attendant and contributor to the latter Society. In 1883, having previously worked as medical registrar and demonstrator of pathology at Guy's, he was appointed assistant-physician; and he also took charge of the skin department. At the time of his death he held the following appointments at Guy's Hospital: Senior Assistant-Physician; Senior Demonstrator of Pathology; Curator of the Museum; being also one of the editors of the Guy's Hospital Reports and Sub-dean of the Medical School. He had thus steadily advanced along the lines of Fagge, Moxon, Wilks, and others, and like them promised fair to be one of the best clinical teachers and pathologists of the day. But perhaps in addition to his scientific as well as medical learning and his teaching capacity, the late Dr. Carrington had endeared himself to his colleagues, contemporaries, and pupils, more especially by his exceeding goodnature and willingness to do any service possible for his friends. The familiar "Bob" Carrington perhaps best expresses the sterling kindness which he was always ready to devote to anyone who required assistance of any kind. He was one of the best examiners at the College of Physicians and at the London University, never losing his temper, even with the most trying candidate. The last important work which he undertook was the editing of Fagge's "Principles and Practice of Medicine," and the amount of patient work and unflagging industry which he gave to his labour of love can scarcely be too highly estimated. Dr. Carrington was a member of the University of London Lodge of Freemasons. For some years past it had been evident to his many friends that he was overworking himself, but the news of his fatal illness came on them with startling suddenness. He got wet on the 11th inst., and had a rigor on the following day; but feeling better on the 13th, he performed a post-mortem examination on a case of acute glanders, but there is no reason to suppose that he contracted infection. In the evening his temperature had risen, and on the next morning Dr. F. Taylor ascertained that he was suffering from double pleuro-pneumonia. He was apparently doing well on the next day, but on Wednesday morning, the 16th, he died rather suddenly and unexpectedly. He was buried at Norwood Cemetery on Saturday last.

To the Editors of THE LANCET.

SIRS,—Though not a Guy's man, allow me to offer a word of tribute to the memory of Dr. Robert E. Carrington, by whose death a career has been closed which gave promise of exceptional brilliancy. Dr. Carrington was well known to many as a loving son to his widowed mother and a devoted brother and friend. Unassuming and self-denying to a fault, ever ready to help in time of need, and a true friend of the poor, his charity was of the noblest type, for of himself he gave. In the conscientious devotion to many duties his mental powers had long outstripped his physical strength. While battling bravely on with but indifferent health, his body became a fertile ground for the ripening of the acute disease which, alas! too soon, has robbed us of a noble life, leaving his loved ones bowed down with sorrow and almost broken-hearted.

I am, Sirs, yours obediently,

London-bridge, S.E., March, 1887. R. DENISON PEDLEY.

ROBERT BRYCE GILLAND, M.D. GLAS., &c.

ON March 8th Dr. Robert Bryce Gilland died at Sevenoaks, at the age of forty-nine. Educated at the University of Glasgow, he obtained his degrees in 1860, became one of the house-surgeons of the Royal Infirmary, and, after finishing his term of office there, was appointed assistant medical superintendent at Gartnavel Lunatic Asylum. From this time he made up his mind to devote himself to the special line of lunacy practice. After two years' residence at Gartnavel, he removed to Essex County Asylum as assistant to the late Dr. Campbell. Thereafter, upon the founding of the Berks County Asylum, he applied for and obtained the onerous and responsible post of medical superintendent of that institution. He was of material assistance to the magistrates in completing the arrangements of this asylum. For seventeen years Dr. Gilland devoted himself to his duties, which he carried out with a precision and earnestness worthy of the highest commendation. It was only necessary to read one of his annual reports to get an idea of his peculiar fitness for the work he had in hand. His method of treating the insane was quite up to the most advanced views of the present day. A marked feature in the routine of the year was his Christmas entertainment, consisting usually of amateur theatricals followed by a ball.

Dr. Gilland was unmarried. Of him it might almost be said that he died in harness. But a short time ago his health broke down. He then, by the advice of his friends, resigned his post, retired to quietude at Sevenoaks, where he peacefully expired on the date above mentioned. Besides holding the degree of Doctor of Medicine, he was a Licentiate of the Glasgow Faculty of Physicians and Surgeons, Member of the Royal College of Surgeons of England, and a Licentiate of the Apothecaries' Company. His remains were removed to Scotland, and interred in the family grave at Kilmarnock.

PRESENTATIONS.—At a public meeting on March 13th at St. Etienne, France, Dr. H. Burroughs was presented with a gold watch in recognition of his services to the McAll French Medical Mission, a branch of which is established in that city. Mr. John Wright Baker, of Derby, who is retiring from practice, was on the 18th inst. entertained at dinner by a large number of his professional brethren of the town and country. In the course of the evening Mr. Baker was presented with an album containing a number of views of Derbyshire and a silver tea-kettle with appropriate inscription.

NORTH LONDON HOSPITAL FOR CONSUMPTION.—At an annual meeting of the Court of Governors of the hospital, Dr. Edwin Howard was unanimously elected a vice-president of that institution.

Medical News.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—Certificates in Hygiene were granted to the following gentlemen, who have passed the required examinatione, on March 21st:

Cantlie, James, M.B. Aberd., Suffolk-street.
Davis, Weston Peel, Gloucester-terrace, Bayswater.
Greenwood, Major, Queen's-road, Dalston.
Gubb, Alfred Samuel, Grove, Hammersmith.
Hitchins, Thomas Johns, Broadfield, Crawley.
James, Charles Alfred, Dispensary, Stoke Newington.
Sanders, John William, M.D. Brussels, Bethnal-green Infirmary.
Webb, Charles Alfred, Brockhurst, Gosport.

COLLEGE OF PHYSICIANS IN IRELAND.—At the March examinations the following obtained licences in Medicine and Midwifery of the College:—

MEDICINE.—Samuel Boake, Arthur Edward Clarke, William Barclay Dick, John Exley, William Isaac Fern, Hu Ruskin Hancock, Frederic William Ord, George Shapland Passmore.
MIDWIFERY.—John Exley, William Isaac Fern, Hu Ruskin Hancock, Vincent Nash, Edward Francis O'Sullivan, Frederic William Ord, George Shapland Passmore.

The undernamed has been admitted a Member:—

Evelyn R. H. Pollard, Staff Surgeon, R.N.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise on March 17th:—

Simson, Francis Taylor, Viceroy-road, South Lambeth.
Tinker, William, Cromwell-road.
Wickham, Onslow Arthur, M.R.C.S., Arundel-square.

IT is officially notified that the Privy Council has sanctioned the bye-laws of the Institute of Chemistry.

DR. JAMES CURTIS, of Cork, has been appointed Inspector of Anatomy for Munster, in the room of the late Dr. Beamish.

MR. THOMAS G. LAW, librarian to the Writers to the Signet Society, has been appointed librarian to the Royal College of Physicians of Edinburgh, in succession to the late Dr. Small.

VACCINATION GRANT. — Mr. John H. Hughes, L.R.C.P. Lond. and M.R.C.S., of the Ombersley district of the Droitwich Union, has received the Government grant for efficient vaccination (sixth time).

HOMES FOR INEBRIATES.—At the annual meeting in connexion with the Homes for Inebriates Association, Dr. Cameron, M.P., was elected president, Canon Duckworth chairman, and Dr. Norman Kerr hon. sec. The three years' work at the Dalrymple Home shows over half the inebriates discharged doing well.

YORK COUNTY HOSPITAL.—At the annual court of the trustees and governors of this institution on the 22nd inst., it was unanimously decided that the York Eye Institution should be amalgamated with the hospital. Satisfactory financial and general reports for the past twelve months were presented and adopted.

ST. JOHN AMBULANCE ASSOCIATION.—The class of Royal Engineer officers held by the St. John Ambulance Association at Chatham, and instructed by Surgeon-Major McNalty, has been examined by the principal medical officer of the district, Deputy Surgeon-General E. Roberts, and out of thirty-four candidates, the whole are reported to have passed an excellent examination in first aid to the injured.

PARKES MUSEUM.—At a meeting held at the Parkes Museum on the 17th inst., Dr. E. F. Willoughby delivered a lecture on George Varrentrapp, sanitarian and philanthropist. A course of twelve lectures by well-known authorities for the special instruction of those desirous of obtaining knowledge of the duties of sanitary inspectors will be delivered in April and May.

THE EPIDEMIC OF MEASLES AND SCARLET FEVER AT GOOLE.—In consequence of the increased number of cases of scarlet fever and measles in the town of Goole, the members of the Goole School Board have decided to close their schools in Alexandra-street and Old Goole for a further fortnight. Alexandra-street Schools have already been closed a fortnight, while those in Old Goole have been kept open.

HYDROPHOBIA IN EGYPT.—An outbreak of rabies and hydrophobia is reported to have occurred at Cairo; a large number of persons have been bitten by rabid dogs and have died of hydrophobia. It is stated that the introduction of the malady is traced to a hound belonging to a European officer, which has bitten several native dogs. Some five or six thousand native dogs have been destroyed, but it is believed that many rabid dogs still remain.

THE RECENT EARTHQUAKES AT MENTONE.—The Rev. Henry Sidebotham, Chaplain of St. John's Church, Mentone, dating from that town, March 18th, writes in the *Standard*:—"I desire to contradict a report which appeared in one of your contemporaries, that 'all the doctors fled' after the earthquake, and to assure your readers that, to my own knowledge, the English doctors, without exception, went their rounds as usual every day, and were ready to attend to all who needed them, although three of them had been rendered homeless by the injury done to their houses."

FOOTBALL.—The final tie for the Inter-Hospital Football Challenge Cup was played on Tuesday last at Richmond, between Middlesex and St. Thomas's. After a well-contested struggle the Middlesex Hospital team was successful, beating their opponents by nearly twenty points. On the same evening the united clubs of Middlesex Hospital held their annual dinner, under the presidency of Mr. A. Hensman, Mr. Henry Morris and Mr. Pearce Gould occupying vice-chairs. The fact that this hospital holds both the Football Challenge Cup and the Rowing Challenge Cup lent additional interest and enthusiasm to the gathering.

THE JUBILEE. — To commemorate the Queen's Jubilee, the Salt family, of Saltaire, have offered to transfer to the public forty-five private almshouses, providing accommodation for sixty people, with extensive grounds and an infirmary, built at a cost of £40,000, as well as £30,000 left under the will of the late Sir Titus Salt for the benefit of the poor people of the district as an endowment fund.—It has been decided to erect a new hospital at Dover, at a cost of from £5000 to £6000, in comemoration of the Jubilee.—At Lewes it has been decided to raise subscriptions for the enlargement and improvement of the local infirmary and dispensary, and to change the name to Victoria Hospital.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ANDERSON, TEMPEST, B.Sc., M.D.Lond., M.R.C.S., has been appointed Ophthalmic Surgeon to the York County Hospital.

BRADBURY, A. F., M.B., B.S., has been appointed District Surgeon to the Salford and Pendleton Royal Hospital.

BULLOCK, B., M.R.C.S., has been appointed House-Surgeon to the Birmingham General Hospital.

CHITTENDEN, H., L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the Third District of the Hitchin Union.

CLARK, ROBERT, L.R.C.P.Ed., L.R.C.S. Ed., has been appointed Medical Officer to the Post Office, Lancaster.

COLLISON, F. W., M.B., C.M.Ed., M.R.C.S., has been appointed Senior House-Surgeon to the Preston and County of Lancaster Royal Infirmary, vice Moore, resigned.

COOK, T. DIXON, M.B., C.M.Glas., has been appointed Medical Officer for the Torquay District of the Newton Union.

DUNCAN, B. ARCEDECKNE, M.D., M.R.C.P., has been appointed Consulting-Physician to the National Hospital for Diseases of the Heart and Paralysis.

GRENFELL, HENRY O., L.R.C.P.Lond., M.R.C.S., has been appointed Assistant Medical Officer for the Infirmary of the Wandsworth and Clapham Union.

HACKETT, H. E., L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer for the Sixth District of the Charlton Union.

HARRIS, H. E., L.R.C.P., M.R.C.S., has been appointed Assistant Medical Officer to the Paddington Workhouse Infirmary.

KINGSFORD, PERCIVAL, M.R.C.S., &c., has been appointed Medical Officer to the Welsh High School for Girls, Ashford, vice Edward Kingsford, F.R.C.S., resigned.

PESKETT, ALFRED FREEMAN, M.R.C.S., L.S.A., has been appointed Medical Officer and Public Vaccinator to the Leyton District of the West Ham Union.

SAUL, W. WINGATE, M.D., M.R.C.S., L.S.A., has been appointed Medical Officer to the Post Office, Lancaster.

WARWICK, FRANCIS J., B.A., M.B. Cantab., M.R.C.S., has been appointed Public Vaccinator for the Shepperton District of the Staines Union.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

BRADFORD INFIRMARY AND DISPENSARY.—House-Surgeon. Salary £110 per annum, with board and washing.

BRISTOL HOSPITAL FOR SICK CHILDREN AND WOMEN.—House-Surgeon. Salary £120.

BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST.—Resident Clinical Assistant.

BURTON-ON-TRENT FRIENDLY SOCIETIES' MEDICAL ASSOCIATION.—Resident Surgeon.

CHELTENHAM GENERAL HOSPITAL.—House-Surgeon. Salary £80 per annum, with board and apartments.

FARRINGDON GENERAL DISPENSARY AND LYING-IN CHARITY, Bartlett's Buildings, Holborn, E.C.—Honorary Physician.

GLOUCESTER COUNTY ASYLUM.—Third Assistant Medical Officer. Salary £105 per annum, with board, lodging, and washing.

HOSPITAL FOR WOMEN, Soho-square, W.—Clinical Assistants. Fee for course of three months, £5 5s.

KENT COUNTY LUNATIC ASYLUM, Barming-heath, near Maidstone.—Third Assistant Medical Officer. Salary £120 per annum, with furnished quarters, attendance, fuel, lighting, milk, garden produce, and washing.

LONDON TEMPERANCE HOSPITAL, Hampstead-road, N.W.—Senior House-Surgeon. Salary 50 guineas per annum, with board and residence.

MANCHESTER ROYAL INFIRMARY.—Resident Medical Officer of the Convalescent Home at Cheadle. Salary £150 per annum, with board and residence.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.—Superintendent of the Laboratory for Original Research about to be established. Salary £200 per annum.

ROYAL GENERAL DISPENSARY, Bartholomew close, E.C.—Resident Medical Officer. Salary £130 per annum, with residence.

ROYAL SOUTH HANTS INFIRMARY, Southampton.—Assistant to the House-Surgeon. Board, lodging, and washing.

SHEFFIELD FRIENDLY SOCIETIES' MEDICAL INSTITUTION.—Resident Medical Officer. Salary £170 per annum, with residence, coal, gas, water and rates free. Accouchements and vaccinations extra.

UNIVERSITY COLLEGE, London.—Professor of Chemistry.

Births, Marriages, and Deaths.

BIRTHS.

ASHWORTH.—On the 19th inst., at Halstead, Essex, the wife of J. Henry Ashworth, M.R.C.P.Ed., of a son.

COMBE.—On the 9th inst., at Holly House, North Walsham, Norfolk, the wife of F. Orloff Combe, M.B., C.M.Edin., of a son.

DAVY.—On the 20th inst., at Southernhay, Exeter, the wife of Henry Davy, M.D., of a son.

MATTHEWS.—On the 19th inst., at Suffolk-street, Pall-mall, the wife of Valentine Matthews, M.R.C.S., of a son.

NEWMAN.—On the 19th inst., at Ivy House, Audlem, Cheshire, the wife of Horace Townsend Newman, M.D., L.R.C.S.I., of a son (still-born).

TWINING.—On the 18th inst., at Salcombe, South Devon, the wife of Alfred H. Twining, M.R.C.S., of a son.

VACHER.—On the 22nd inst., at 31, Shrewsbury-road, Birkenhead, the wife of Francis Vacher, F.R.C.S., of a son.

MARRIAGES.

GUINNESS—REED.—On the 17th inst., at the Great Assembly Hall, Mile-end-road, Harry Grattan Guinness, M.R.C.S., to Annie, daughter of the late Henry Reed, Esq., of Mount Pleasant, Launceston, Tasmania.

MURRAY—VOSS.—On the 22nd inst., at St. James's, Piccadilly, Hubert Montague Murray, M.D., to Florence, third daughter of the late John Matthew Voss, of Swansea.

DEATHS.

BRODIE.—On the 15th inst., at the Royal Victoria Hospital, Netley, Surgeon John Brodie, M.B., Medical Staff, aged 38.

CARRINGTON.—On the 16th inst., at St. Thomas's-street, Southwark, after two days' illness (of pneumonia), Robert Edmund Carrington, M.D., F.R.C.P.Lond., Senior Assistant Physician, Guy's Hospital, in his 34th year.

HALL.—On the 18th inst., at his residence, Gorse Bank, Werneth, Oldham, William Hall, M.R.C.S., late of Salford, aged 61.

JACKMAN.—On the 21st inst., Edith, wife of William Thos. Jackman, M.R.C.S., of 114, Brixton-hill, and daughter of the late Mrs. Edward Radclyffe, of 61, King Henry's-road, South Hampstead, in her 34th year.

MACGILL.—On the 17th inst., Andrew MacGill, M.D., late of Church House, St. Leonards-road, Poplar.

THORNTON.—On the 20th inst., at Hastings, William Henry Thornton, J.P., M.R.C.S., of Berkeley Lodge, Margate, aged 65.

THURLAND.—On the 23rd inst., at Wilmington-square, W.C., Francis Edward Thurland, M.R.C.S., L.S.A., aged 40.

WOOLHOUSE.—On the 13th inst., at Cadogan Lodge, St. Mary's-crescent, Leamington, George Richard Woolhouse, M.R.C.S., L.S.A., Army Medical Department, retired, formerly in H.M.'s 44th Regiment, aged 65.

WOOLLETT.—On the 19th inst., at his residence, The Mount, Newport, Mon., Robert Francis Woollett, M.R.C.S., L.S.A.—R.I.P.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, March 28.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M.; Thursday, 2.30.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesday, 2.30 P.M.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

SOCIETY OF ARTS.—8 P.M. Prof. W. C. Unwin: Machines for Testing Materials, especially Iron and Steel (Cantor Lecture).

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Clinical Evening: Dr. J. Hughlings Jackson: (1) Case of Hemianopsia and of Wasting and Paralysis of One Side of the Tongue in a Syphilitic Patient; (2) A case of Facial Paralysis with Paralysis of the Palate from Cerebral Disease.—Dr. Samuel West: (1) Case of Post Hemiplegic Hemichorea in an Adult; (2) Case of Jacksonian Epilepsy.—Dr. de Havilland Hall: Two cases of Ulceration of the Soft Palate and Pharynx.—Mr. Lennox Browne: Case of Lympho-sarcoma of the Tonsil and Pharynx.

Tuesday, March 29.

GUY'S HOSPITAL.—Operations, 1.30 P.M. and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 1.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M.

ROYAL INSTITUTION.—3 P.M. Prof. Gamgee: Function of Respiration.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. Priestley: Pathology of Intra-uterine Death (Lumleian Lecture).

SOCIETY OF ARTS.—8 P.M. Mr. Richard Bannister: Colonial Wines.

Wednesday, March 30.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.

CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M.; Saturday, same hour.

SOCIETY OF ARTS.—8 P.M. Mr. A. Beckenzaun: Electric Locomotion.

Thursday, March 31.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Ophthalmic Operations, Friday, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ROYAL INSTITUTION.—3 P.M. Prof. F. Max Müller: Science of Thought.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—5 P.M. Dr. Priestley: Pathology of Intra-uterine Death (Lumleian Lecture).

Friday, April 1.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—8 P.M. Clinical Evening. Cases will be shown by Mr. Keetley, Dr. Scanes Spicer, Dr. Seymour Taylor, Mr. Edwards, Dr. Colcott Fox, Mr. Bland Sutton, and others, Dr. W. G. Stevenson and Mr. Bruce Clarke: A Demonstration upon the Living Subject of the Treatment of Stricture of the Urethra by Electrolysis.—Dr. Alderson: Remarks upon a case of Fracture of the Patella, treated mechanically twenty-five years ago, with specimen. Pathological Specimens:—Mr. H. Percy Dunn: (1) Epithelial Growth of Pharynx; (2) The Skull from a case of Traumatic Meningocele.—Mr. G. A. Webster: Fracture of the Astragalus.—Brigade-Surgeon W. Curran: A Collection of Water-colour Drawings.

CLINICAL SOCIETY OF LONDON.—8.30 P.M. Sir Dyce Duckworth: A case of Psoriasis, with associated Rheumatism, which passed into Pityriasis rubra (*Dermatitis exfoliativa*).—Mr. Bellamy: Case of Symmetrical Gangrene following Varicella.—Mr. Lane: A case of Intussusception produced by a Tumour growing from the Mucous Membrane of the Great Gut.—Mr. Pollard: Three cases illustrating the Difficulties in establishing Natural Respiration after Tracheotomy, and their Treatment by Tracheal Catheterisation.—Dr. Drewitt: A case of Lupus treated partly by Salicylic Acid, partly by Scraping (living specimen).

ROYAL INSTITUTION.—9 P.M. Prof. Dewar: Light as an Analytic Agent.

Saturday, April 2.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

ROYAL INSTITUTION.—3 P.M. The Rt. Hon. Lord Rayleigh: On Sound.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

THE USE OF UNCOOKED MILK.

A CORRESPONDENT, referring to our recent comments concerning the danger of using uncooked milk, asks, with regard to the prevention of infectious diseases, what our views are as to cream, butter, and cheese. We have always regarded cream as a necessary constituent of milk, and we have again and again recorded outbreaks of infections diseases as associated with the use of cream. The most recent was that which prevailed in connexion with the use of cream from a dairy in Shoreham, the cream being mainly consumed as an adjunct to strawberries. Cream, whether as the result of the mere mechanical process of its formation or otherwise, seems to have a special facility for embodying any injurious properties that may attach to the milk from which it rises. If milk which has not travelled by rail be boiled when delivered, a cream will later on form on its surface, to which no such danger attaches. As to butter, we are not aware that it has constituted a vehicle for the infection of the ordinary specific fevers. Although this subject cannot yet be regarded as having been exhaustively dealt with, yet in several outbreaks butter has, in common with other foods, been carefully inquired into, but without positive results. Whether the process of butter-making has to do with this or not cannot at present be stated. Much the same applies to the question of cheese; but, as we explained in our issue of March 5th, a distinct danger does attach to the use of certain cheeses, and this it probably connected with the quality of milk that is used in the process of manufacture.

Mr. W. Outhwaite.—We shall be pleased to hear "the other side" from our correspondent, but have not space for the verses. We freely admit that there is danger attached to all sports; but football is unfortunately distinguished by the number and severity of accidents and the roughness of the play.

Mr. W. Fraser (Ashburton).—The report has been received.

ERYSIPELAS AND VACCINATION.

To the Editors of THE LANCET.

SIRS,—Your article on the above subject suggests the desirability of treating the vaccine vesicles, when ruptured, with antiseptics. Is this done to any extent at the present time? Or are there any instructions on this point issued by the vaccination authorities?

I am, Sirs, your obedient servant,

March 19th, 1887. INQUIRER.

*** There are no instructions issued which relate especially to broken vesicles. There would obviously be some difficulty in the antiseptic treatment of poor children remaining in their own homes.—ED. L.

PROBABILITY OF LIVING AND OF DYING.

Mr. J. Niven (Oldham).—The communication has been referred to Mr. Noel A. Humphreys, the editor of Dr. Farr's "Vital Statistics," who agrees that the paragraph quoted involves an undoubted oversight, which appears to have arisen in the following way. In the paragraph in question Dr. Farr uses p to represent the "probability of *dying*," whereas this letter is almost invariably used only to represent the "probability of *living*," and in the formula given to express the relation of p and m the p has its usual signification, the "probability of *living*," instead of the unusual meaning attached to it in the preceding paragraph. The true difference between the rate of mortality (m) and the probability of *dying* may be expressed: $m - \frac{2m}{2+m} = \frac{m^2}{2+m}$, and this difference, as is explained in the paragraph, becomes less as m diminishes.

Old Subscriber.—The letters sent scarcely supply material for a judgment on the institution.

Mr. Harcourt (Belfast) should consult a surgeon.

DIPHTHERIA AND CROUP AS ENDEMIC DISEASES.

To the Editors of THE LANCET.

SIRS,—It seems surprising, with all the efficiency of the staff of medical officers of health, that no, or very little, progress has been made in hunting down contagious disease to its seed bed (endemic origin), particularly as so much progress has been made in tracing contagion—e.g., scarlatina, typhoid, diphtheria, &c.,—to milk or water. The Jennerian analysis has doubtlessly been more strictly applied to the latter than to the former. I have for many years held that diphtheria and croup had their "endemicity" in stables or stable manure. To this opinion I was led by the fact that the majority of patients whom I had to treat were either connected with or lived near stables—e.g., stablemen, cowmen, &c., and their families. So strongly did I hold this opinion that when the Princess Alice died I wrote suggesting that all the localities, &c., where the young princess, in whom the disease first declared itself, was likely to have visited should be found out, laying particular stress on any chance visit to stables. It has occurred to me to verify in a certain degree the truth of my opinion. Last year I had a hen set in my stables. She was perfectly isolated from the other chickens, though fed on similar food and water, for a period of about twelve days, when she was brought to me with a "stoppage in the throat." I examined her, and found that the fauces, &c., were covered with the usual white membrane of diphtheria. In detaching the membrane the surface oozed blood—in fact, there was no doubt in my mind as to the nature of the case. I treated it for a few days, mopping out the throat with a saturated solution of common salt (about the best germicide solution I know), and as she did not improve I had her killed. Since then I obtained a book on poultry, and in it I find that diphtheria and croup are diseases from which fowls suffer. Whence can the birds get the disease, except from their own surroundings—farmyards, stables, &c.? It is next to impossible that the disease could be imported amongst them, as they are generally quite isolated. I know nothing of veterinary science, and consequently am very diffident in expressing an opinion which I am inclined to hold—that glanders is diphtheria in the horse. If such be the case, it very much strengthens my contention that the disease is endemic in stables (of course, it may be endemic elsewhere). I am, Sirs, yours faithfully,

Long Ditton, March, 1887. HENRY GODRICH, B.A., 1st B.Sc. Lond.

MEDICAL MISSIONARY WORK IN BEIRUT.

THE physicians of the medical department of the Syrian Protestant College have been appointed by the Order of St. John in Berlin as the medical attendants of the Johanniter Hospital in Beirut. This admirable charity is served, too, by the deaconesses of Kaiserwerth, and has received during the past year 465 in-patients and 7126 patients treated in the polyclinique. Our readers may remember that the College is connected with the American Presbyterian Mission.

M.B., F.R.C.S.—Our correspondent's experience must be peculiar. For many hospital appointments the possession of the higher diploma is indispensable.

M. M.—There is no invariable rule.

H. M.—Yes. The blocks to illustrate the paper should be sent.

WORKMEN'S COLLECTIONS IN AID OF HOSPITALS.

To the Editors of THE LANCET.

SIRS,—The workpeople of our town are showing a desire to establish a "Saturday Collection" in aid of our infirmary. It is thought that information from other towns adopting similar weekly collections will contribute largely to the success of the movement. I am requested to assist in obtaining such details; and as the difficulties are great, I must appeal for assistance to those gentlemen who are attached to hospitals where this plan is in satisfactory operation to forward to me a copy of their report. Personally I shall esteem each report a great favour, and the good likely to result to an infirmary will in itself afford satisfaction.

I am, Sirs, yours obediently,

SAMUEL STRETTON,

March, 1887. Consulting Surgeon, Kidderminster Infirmary.

THE MOXON MEMORIAL FUND.

PRESIDENT: Sir William Jenner, Bart., K.C.B., M.D., F.R.S. The following contributions have been received since those announced on March 19th. All subscriptions should be forwarded to the Honorary Treasurer, R. Clement Lucas, B.S., F.R.C.S., 18, Finsbury-sq., E.C., by whom they will be acknowledged. Cheques should be crossed, "City Bank."

Fourth List.

Subscriptions announced	£197	4	6	J. Mitchell Bruce, M.D.	£1	1	0
Sir Andrew Clark, Bart.	21	0	0	W. C. Church, M.D. ...	1	1	0
L. C. Wooldridge, M.D.	3	3	0	J. C. Roberts, Esq. ...	1	1	0
R. Elphinstone, Esq. ...	3	3	0	A. E. Mayiard, M.B., B.S.	1	1	0
Mrs. Peachey	3	3	0	J. Sykes, Hsq.	1	1	0
Brigade-Surg. J. Wales ..	2	2	0	E. W. Thurston, Esq. ...	0	10	6
J. A. Ball, M.D.	1	1	0	O. B. Shellswell, Esq. ...	0	10	6
James Bunting, Esq. ...	1	1	0	Staff-Surg. C. Godding, R.N.	0	10	0

G. A. Wright, M.B., F.R.C.S.	1	1	0				

M. A. O.—The only guide to the examinations at the London College of Surgeons is that by Mr. Gant (fifth edition, 4*s.* 6*d.*, Baillière, Tyndall and Cox). Keetley's "Guide to the Medical Profession" would afford the desired information on the other points.

Mr. A. V. Dyer will find his question answered in the letter of our Paris correspondent, (p. 650.)

House-Surgeon will find the report in our present number.

THE INFLUENCE OF ALTITUDE ON PHTHISIS.

To the Editors of THE LANCET.

SIRS,—I notice in your issue of March 19th an article by Dr. Alcock, wherein a novel explanation is sought to be given of the benefit derived from high altitudes in the treatment of phthisis. His idea is ingenious, but his reasoning is fallacious; and, as a matter of fact, his explanation cannot be true. He endeavours to show that the particles of human blood have the same average rate of heat motion at St. Gothard that they would have had at the sea-level at a temperature of 104·8°; it is his arguments in support of this proposition that are unsound. His words are:—"It is already accepted that the only difference between the liquid and gaseous states is one of molecular motion. Consequently, if 199° of heat can make water boil at St. Gothard, it is apparent that this temperature can there produce an amount of molecular motion which not less than 212° could excite at the sea-level." In other words, because steam contains more molecular motion than water, therefore steam raised at all temperatures contains the same amount of molecular motion! Such is Dr. Alcock's argument. He now continues: "Further, as 199° is to 212°, so is 98·4° to 104·8°; therefore, the rate of motion to which a temperature of 98·4° would give rise at St. Gothard could only be attained at the sea-level as the result of a temperature of 104·8°." Here the condition of water at 98·4° and 104·8° is deduced from the condition of steam at 199° and 212°. But in spite of the fact that "the only difference between the liquid and gaseous states is that of molecular motion," Dr. Alcock has no more right to assume that the laws which apply to gases apply also to liquids than he has to assume that Boyle's law applies alike to water and steam. Again, he assumes equal rates of motion for proportional temperatures Fahrenheit. But why Fahrenheit? Why not Centigrade, or Réaumur, or any other scale? If there were any truth whatever in Dr. Alcock's assumptions, would not the use of the absolute temperature be the more likely to give correct results? But, as a matter of fact, neither are his assumptions true, nor, if they were, would his conclusions follow.—I am, Sirs, your obedient servant,

H. OSBORNE FOUNTAIN, B.A. Cant., M.R.C.S., L.R.C.P.

March 22nd, 1887.

THE CROYDON AND SURREY MEDICAL AID ASSOCIATION.

OUR attention has been called to the fact that circulars advertising this Association and its medical officers are distributed from house to house, and that weekly canvassers are employed. There seems, too, no wage limit to the admission of members. Yet we see appended to the circulars the names of many gentlemen who would not willingly be parties to anything undignified or unprofessional.

Mr. Geo. A. Craig, M.B.—The gentleman named died in March last year.

VIPER'S OIL.

To the Editors of THE LANCET.

SIRS,—I was lately consulted by a patient for gradually increasing deafness, for which she had tried various domestic remedies without success. Among others she mentioned, with some surprise at its failure, that she had "rubbed in viper's oil," procured for her by her friends, and that "they had been very particular, catching them themselves." I should be curious to know if any of your correspondents can give an account of the origin of this singular superstition. Does it arise from the passage of the "deaf adder that stoppeth her ears and refuseth to hear the voice of the charmer," on the idea of *similia similibus curantur?* I did not inquire as to the expense of the preparation, but it must be considerable, as the average viper would not, one would suppose, yield much oil under any method of treatment.

I am, Sirs, yours faithfully,

March 10th, 1887. CHATHAMITE.

THE QUEEN'S JUBILEE AND THE HOSPITALS.

ON this subject, *Mr. Ernest Dereuth*, Secretary to the City Orthopædic Hospital, writes:—"At the commencement of the year, I made similar attempts to those so kindly advocated by Dr. Slight, and your own journal, supported by a few well-known philanthropists, but the daily papers, although usually giving me a helping hand for my hospital, declined giving publicity to our letters and announcements till the consent of Her Majesty had been obtained. I shall be very pleased to afford the movement my utmost exertions, and would suggest that a body of gentlemen be formed as soon as possible as a preliminary committee."

Liverpool.—We do not give medical advice.

CASE OF CUT-THROAT.

To the Editors of THE LANCET.

SIRS,—The following report of a case of cut-throat may be worthy of a corner in your journal.

A few days ago I was called to a patient who had laid violent hands on himself. When I got to the house I found a man sitting on a bed bleeding profusely. I at once examined him, and found a wound which stretched across the throat, being placed between the thyroid cartilage and hyoid bone. The thyroid was fractured, due to his tearing it with his fingers. I at once placed a sponge wrung out of cold water over the wound, and sponged the blood. I repeated this as the blood continued to flow, but eventually the bleeding ceased. After half an hour another doctor came; but as the bleeding had abated he did not interfere. Two hours later the bleeding recommenced; so we sponged the part well, and found four small arteries from which blood spouted. These we ligatured with silk, and the bleeding was completely stopped. The next consideration was, should we sew the wound up? We agreed not to do so, being apprehensive of blood accumulating between the skin and opened larynx, and, by passing into the lungs, causing asphyxia or inflammation. The wound was therefore left completely open for two days. Two silver stitches were then placed near the sides of it, leaving an opening over the larynx, so that any discharge from it might have free drainage. I examined the pupils as soon as I arrived, and found them greatly contracted. The wound is now closed by silk stitches. It is sponged twice a day with tepid water, and then a clean piece of linen is placed over it. The patient takes a little tea and milk, and a pint of beef-tea has been administered by the stomach-pump. No bad symptom has as yet been noticed.

I am, Sirs, yours faithfully,

Bridlington Quay, March, 1887. G. NELSON, L.R.C.P., L.R.C.S., &c.

P.S.—Since the above was written the severed pharynx has nearly healed, which is proved by very little fluid coming through the external wound when the patient swallows any fluid. As far as I can make out, the fractured thyroid cartilage is also united, and there is now very little discharge through the external wound, which now only admits one finger. The urine is loaded with urates and a quantity of bile. The bowels cannot be made to act by enema; nevertheless, we shall, I think, effect a good cure.

NIGHTMARE.

To the Editors of THE LANCET.

SIRS,—I am much indebted to the correspondents who so kindly replied to my letter, especially to "R. W. W." for the prescription given. It has not had, I regret to say, the desired effect. The dreams, with irritable heart and weakened nerve force, continue. I may add that there is some history of gout and further signs of deranged nutrition in the urine being sometimes loaded with lithates, slight flatulence and inertia of liver. Heart sounds healthy, and no excesses. Change has not done any good and exercise is limited, as a slight amount excites the heart and causes fatigue. I am, Sirs, yours faithfully,

March 22nd, 1887. M.D.

To the Editors of THE LANCET.

SIRS,—In reply to the letter of your correspondent, "M.D.," in your issue of the 19th ult., I beg to suggest the following hints:—Diet chiefly meat, eggs, milk, cold bacon; no wine or spirits, but good stout; cod-liver oil; vigorous friction of entire chest with embrocation twice a day; strictly early hours; a month's holiday in June in such bracing upland air as that of Strathpeffer. These are to my mind essential points. If the liver be sluggish, short, brisk horse exercise before breakfast is invaluable. As a rule, I believe iron is better avoided.

I am, Sirs, yours truly,

March, 1887. F.

COLONIAL PRACTICE.

To the Editors of THE LANCET.

SIRS,—Will some of your readers kindly advise me? My wife is not strong, and I am told she must not winter in England again. I have no funds to send her to the south of France, &c., so have made up my mind to sell my practice and make a start in the colonies. Which is the best place to go to? I should prefer a good assistantship, and, if possible, one with view to partnership. I would be glad also to learn the name of the most reliable medical agent in Australia or New Zealand, to whom to write. Any information will be most thankfully and gratefully received. I am, Sirs, yours faithfully,

March, 1887. SPES.

THE M.R.C.S. DIPLOMA.

IN reply to a correspondent, whose letter has been mislaid, we have to state that a holder of the Membership of the Royal College of Surgeons has the right to append "M.R.C.S." to his name, and he only.

Furlough.—We do not think our correspondent sufficiently realises the necessity for individual convenience giving way to the exigencies of the service, nor do we approve of the manner in which he writes of the administrative officers of the department, who are certainly entitled to credit for their labours in investigating questions connected with the prevention and treatment of disease.

G. P.—The matter shall have attention.

Mr. R. W. H. Thomas.—We are unable to refer to any specific authority.

ANOSMIA.

To the Editors of THE LANCET.

SIRS,—I would feel extremely thankful if any of your numerous correspondents would kindly suggest some line of treatment that might assist me in a case I have at present. My patient, a gentleman aged thirty-four, has been for many years deprived completely of the sense of smelling; and is now a great sufferer from headaches (usually frontal), which is brought about without any apparent cause. Excitement of any kind induces it. I can find no history of syphilis, and he enjoys otherwise good health. He is very abstemious, and most careful in dieting himself. I find his breath is most offensive, which he says has been so for years.

I am, Sirs, yours faithfully,

March 23rd, 1887. CONSTANT READER.

GAS-BURNERS FOR THE CONSUMPTION OF SEWER GAS.

To the Editors of THE LANCET.

SIRS,—I observe in THE LANCET of last week a letter from Mr. Godrich, advocating the use of gas-burners for the combustion of sewer-gases. I beg to say that I have already constructed and patented an apparatus for this purpose, from a suggestion of Dr. Lowe, which acts perfectly. I shall be glad to show it in action to any member of the medical profession who may care to see it. I am, Sirs, your obedient servant,

Park-street, March 22nd, 1887. R. W. HELLYER.

BREAD-MAKING.

To the Editors of THE LANCET.

SIRS,—Could any of your readers inform me where I might obtain a pamphlet, written many years ago, on a method of preparing bread with carbonate of soda and muriatic acid very diluted. I know I ate some when in London many years ago, and I thought it healthy. I would be satisfied if I knew the quantities to be used.

I am, Sirs, yours respectfully,

Conway, N.W., March 21st, 1887. ROBERT JONES.

Student should make application to the Secretary of the College.

M.D. has not enclosed his card.

COMMUNICATIONS not noticed in our present number will receive attention in our next.

COMMUNICATIONS, LETTERS, &c., have been received from—Dr. Braxton Hicks, London; Dr. Macewen, Glasgow; Mr. Warrington Haward, London; Dr. O. Sturges, London; Mr. McGill, Leeds; Prof. Senn, Milwaukee; Sir E. Lechmere, London; Mr. Mandagnialidi, Colwyn Bay; Mr. Gant, London; Sir H. C. Perrott, London; Mr. Urban Pritchard, London; Mr. Jas. Turton, Brighton; Mr. A. M. Sheild, London; Mr. T. B. Young, Halesowen; Mr. P. B. Hill, Crickhowell; Dr. F. H. Alderson, London; Mr. Grant, Blantyre; Dr. J. W. Moore Dublin; Mr. Mansfield-Jones, London; Mr. G. Nelson, Bridlington Quay; Mr. R. D. Pedley, London; Mr. J. L. Stretton; Mr. Leighton Kesteven, Brisbane; Mr. A. V. Dyer, Clifton; Messrs. Croonian Lectures
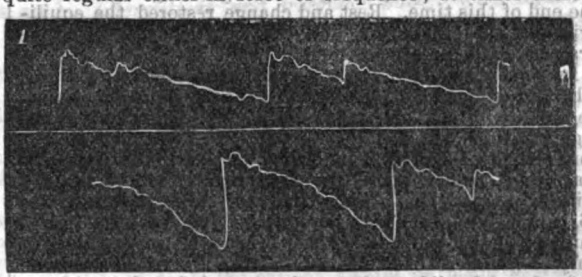
ON
THE PULSE.

Delivered at the Royal College of Physicians of London, March, 1887.

By W. H. BROADBENT, M.D., F.R.C.P.,
PHYSICIAN TO ST. MARY'S HOSPITAL, CONSULTING PHYSICIAN TO THE LONDON FEVER HOSPITAL, AND PRESIDENT OF THE CLINICAL SOCIETY.

LECTURE II.

MR. PRESIDENT AND GENTLEMEN,—My first lecture was occupied by certain general considerations with regard to the pulse, after which I began to describe the more important variations in frequency and abnormalities of rhythm. The next to be considered is the infrequent pulse.



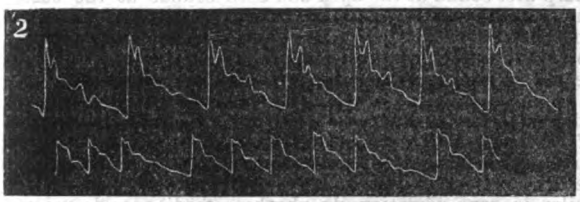
Infrequent pulse.—It has already been remarked that the effect upon the pulse of nearly all departures from a normal state of health is to increase its frequency, and the diseases are extremely few which reduce the pulse rate in any marked degree. High tension in the aorta—induced experimentally in animals or man by pressure upon the abdominal aorta, or upon a number of the larger arteries—slows the pulse, and the high tension of renal disease has some effect in the same direction, but less than might have been anticipated. In jaundice the pulse falls in frequency, and in various affections of the nervous system this effect is observed; but, except under circumstances which will be discussed later, the reduction is not striking. A pulse is really infrequent when the number of beats is below 40 per minute. A pulse of 60 is not uncommon, of less than 60 rare. Persons are met with, however, in the enjoyment of vigorous health with a pulse of less than 40. I have known an athletic young man, tall, well built, and muscular, who distinguished himself at football and other violent games, whose pulse-rate was 36. Some years after I last saw him, I heard of his death while swimming; he was taken with "cramp," so-called, and sank. In this cramp it is the heart which is brought to a standstill by the resistance in the peripheral circulation due to the combined effects of arterio-capillary contraction from contact with the cold water, and of pressure on the surface from immersion, and it is not unlikely that slow action of the heart would predispose to this result. Infrequency of the pulse to the degree under consideration is sometimes met with in fatty degeneration of the heart, and is enumerated among the indications of this disease, but it is far more commonly absent than present, even in an advanced stage of fatty change in the heart.

The infrequent pulse, however, is so closely associated with the bigeminal pulse, and with a peculiar modification of the rhythm of the heart, in which only every other beat reaches the wrist, that it will be well to consider these. In the interesting variety of pulse rhythm called the "pulsus bigeminus," the beats come in couples, a strong beat being followed quickly by a somewhat weaker one, after which there is a pause. The second of the two beats may vary greatly in strength, being sometimes almost as distinct as the first, sometimes scarcely perceptible, and the interval between the first and second may vary somewhat in length. On examining the heart, its action is found to correspond; there are two unequal impulses, the second weaker than the first, and usually felt at a different point; and on auscultation the sounds associated with the second impulse are less loud, and of a lower pitch. If a murmur is present, usually a mitral systolic, it will be louder and higher pitched with the first, and may be inaudible with the second. I have sometimes heard a mitral murmur with one beat and a tricuspid with the other.

Closely allied to this condition is that in which there are two beats of the heart to one of the pulse, one beat being dropped; not that transitions are common, for, in the absence of valvular disease, the pulse may number 40 one minute, the heart beating 80 in couples, and the next may be perfectly regular at 80. In the form of valvular disease, however, mitral stenosis, in which the pulsus bigeminus and the dropped beat are most frequently met with, the former may be a stage in the return towards a regular mode of action from the latter; and although (in the absence of valvular disease) a systematic bigeminal pulse does not succeed the dropping of a beat, yet an occasional bigeminal beat occurs when the weaker systole happens to raise the aortic valves, so that there is a clinical similarity which permits of their being considered together. Both, as has just been said, are met with in mitral stenosis, and especially when under treatment by digitalis. I have had several cases in which the pulsus bigeminus, or dropping of one beat, could be induced at will by administering this drug. Taking the more advanced condition, when there are two beats of the heart to one of the pulse, a careful examination of the heart is most instructive. It is often difficult to resist the impression that the two ventricles are acting alternately. The impulse in the first of the two beats will give the sharp apex tap characteristic of an advanced stage of this form of heart disease; the second will be felt only, or mainly, over the right ventricle. On auscultation, if there is regurgitation as well as stenosis, the systolic murmur and short sharp first sound will be heard at the apex with the first beat, but will be absent at the second; and the same will be the case with the aortic second sound at the base—it will be distinct with the first, absent at the second; while the sounds of the right side of the heart will be heard alone at the second beat with the tricuspid regurgitant murmur, if one is present, and will be comparatively weak with the first and stronger of the two beats; the pulmonary second sound, however, bearing witness that the right ventricle has contracted. When there is no regurgitation, the first beat will have the loud, short, sharp first sound at the apex and both sounds at the base, the second the low-pitched first sound of the right ventricle and a loud pulmonary second sound, but no aortic second sound. Usually the presystolic murmur will have disappeared before the coupled beats under consideration set in.

In the absence of mitral stenosis the double heart beat with only one pulse is considered by Tripier of Lyons to be of very serious import, and to occur only in connexion with epileptiform attacks. To quote his conclusion on this point, he says: "Il semble donc qu'il n'y a pas de pouls lent avec épilepsie sans déviation du rhythme cardiaque, de même qu'il n'y a pas de déviation du rhythme cardiaque avec ralentissement du pouls sans épilepsie, ou sans l'action du digitale, tout au moins d'après les faits dont nous avons connaissance." Such has not been the case in my own experience. But before relating the cases which seem to me to be in opposition to Dr. Tripier's conclusion, I may add one more to the series which he has collected with so much industry and employed with so much ability, illustrating the connexion upon which he insists between epileptiform attacks and the dropped beat and bigeminal pulse.

C. W——, a carman, aged forty-seven, but looking ten years older, was admitted into St. Mary's Hospital under my care, March 2nd, 1877. He had had rheumatic fever eight years before, and had suffered from occasional attacks of bronchitis. For eighteen months he had complained of palpitation after hard work, and he had had "fits," of which no exact description was obtained. After a recent attack of bronchitis, from which he had recovered about three weeks, he had had for a fortnight an increasing sense of palpitation of the heart, with pain which he called "working pains" across the upper part of the abdomen. On admission he had an anxious look and the skin was clammy; the temperature 97°; the urine had a specific gravity of 1010, but contained no albumen; the pulse was 31, large and strong, not quite regular either in force or frequence; at times there

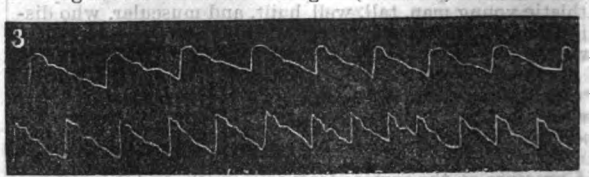


was an echo of the beat (pulsus bigeminus)—see Chart I. The heart was of normal size; the apex beat was distinct, and often followed at a brief interval by a second beat. At the apex a low-pitched systolic murmur beginning with an accent was heard; it was soon lost beyond the

Digitized by Google

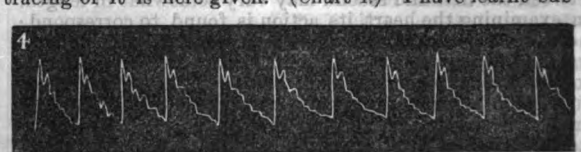
apex, but within it, was audible over the right ventricle and up to the pulmonary area. The aortic second sound was heard over the entire heart. As a rule the heart beat was single, but from time to time there was a double beat. When he was made to walk rapidly the patient felt faint, but did not stagger, and secondary beats were more numerous. He was in the hospital two months, and improved much in strength, no fits occurring; the pulse, however, remaining at 28. At one time, when suffering more than usual from "working pains" all over the abdomen, the pulse was 59 and quite regular. His subsequent history is unknown.

A well-marked example of infrequent pulse with double heart beat, but without epileptiform attacks or serious effects on the health, came under my notice in November, 1883, in a tall, strong, broad-chested man, aged fifty-two years, who had been engaged in exciting political agitation, and had suffered a severe domestic loss. He was complaining chiefly of continuous dreaming, and of depression and loss of energy, with heaviness and confusion of the head. Having found a pulse of 40, I wished to examine the chest, but he said this was quite unnecessary, since, whatever else might be amiss, the heart and lungs at any rate were all right, and he declared that he would walk up-hill as well as ever, and even run. There was no impulse or apex beat, but on auscultation a normal first and second sound were heard all over the heart; followed rather sooner than usual by a first sound without a second, a weak pulmonary second sound, however, being audible when listened for with care. The first of the two beats only gave a pulse at



the wrist; the second, indeed, not raising the aortic valves. All the symptoms disappeared, but two years later, after another period of excitement and anxiety, he again consulted me, and with similar complaints he had a return of the peculiar action of the heart. The pulse was 34, quite regular. There was a diffused double cardiac impulse without defined apex beat, one of them strong, giving a pulse, followed quickly by a weaker one, which sent no wave to the wrist. The sounds were much as they have been described before, but the first sound of the second weaker beat was almost inaudible at the apex and distinct over the right ventricle. This patient again recovered, and is still making much noise in the world.

In the same year, 1881, I saw a medical man of about fifty-five, who, when rather overtaxed by work, had run some distance on being called to an urgent case. This was followed by strange faint feelings, and an uneasy sensation about the heart. He was not otherwise out of health. He had discovered that his pulse was 40 instead of 70, and on examination this was found to be due to the heart beating in couples—a strong beat with normal sounds which gave a pulse, followed quickly by a weaker beat with sounds which appeared to belong to the right ventricle only. This had been going on for ten days before I saw him, and continued for ten or fourteen days longer, coming and going towards the end of this time. Rest and change restored the equilibrium of the circulation, and this gentleman is in active practice at the present moment.



In November, 1883, I saw a gentleman, aged fifty-three, who had enjoyed good health until the previous June, when he had an attack of congestion of the lungs, and mitral regurgitation was found to exist. He looked well, but complained of shortness of breath on exertion. The pulse was large, rather tense, perfectly regular at 72 beats a minute, except that from time to time the rate was 36, which was found to be due to the fact that while this continued the beats of the heart were in couples, one only of which reached the wrist. The apex beat was well defined and forcible, and near the normal situation. A long, smooth, high-pitched, musical murmur was heard at and to the left of the apex and in the back; another murmur of lower pitch was audible along the right edge of the upper part of the sternum up to the sterno-clavicular articulation; the aortic sound was accentuated, the pulmonary masked by over-lapping lung. When the coupled beats were present, no second sound followed the later of the two, so that the sounds ran 1 2 1—1 2 1; both the mitral and the aortic murmur were louder with the first beat than when the heart's action was regular, and absent or scarcely audible with the second; this second beat, however, gave a loud first sound, so that it was not abortive from mere weakness, but the absence of the murmurs and of the second sound was probably due to an imperfect diastole. A week later, after rest in bed, the physical signs were unchanged, except that when a series of coupled beats occurred, which was as frequent as before, the second of the two beats was weaker and more precipitate. This patient, after a Mediterranean trip, again came under my care in February, 1884, and was then observed to have Cheyne-Stokes' respiration, which, however, did not prevent him from going to the City, until thrombosis of the deep tibial veins came on. He died from the effects of thrombosis in the right innominate vein. The peculiar heart rhythm was never heard again; but the case is the more interesting from the occurrence of this peculiarity in the action of the heart, and later of Cheyne-Stokes' respiration, which Tripier considers to belong to the same order of phenomena.

The double heart beat for each beat of the pulse was present again in the case of a lady seen in October, 1885. She had worked very hard in her father's parish, which involved much walking up-hill, from April to June, when she began to look ill, and was breathless—which, however, she did not notice herself. She then suddenly broke down, and had been resting up to the time when she consulted me. She looked well, and all the functions were natural, but she felt as if she could sleep continually. The pulse was infrequent, and two beats of the heart, one like an echo of the other, were felt and heard for every pulsation at the wrist. The aortic, as well as the pulmonary second sound, seemed to be audible in the second weaker beat, although no evidence of this systole having raised the aortic valves is recognisable in the tracing. (Chart 3.) Under the

excitement produced by the application of the sphygmograph the rhythm gradually became normal—not suddenly, as is usual.

Another case has recently come under my notice in a gentleman aged sixty-three, who consulted me on account of faintness and flatulence. He had been nervous about his heart for thirty years or more, and had been afraid of exercise. He had neither overwork nor anxiety; but some months before he consulted me he had had a fall from his horse and had broken his collar-bone, since which he had not ridden. The pulse was at first 108, and regular, but from agitation, or from the effort of taking off his coat, it fell to 54, the number of heart beats being exactly double, a strong and weak beat being coupled together with sounds belonging predominantly to the left and right ventricle respectively. This continued to the end of the interview, and a tracing of it is here given. (Chart 4.) I have learnt sub-

sequently from his regular medical attendant that this rhythm has been observed from time to time for years. In none of these cases had epileptiform or syncopal attacks been known to occur.

Still more recently I have seen with Mr. Stanley Smith an example—the only one I have met with, except, as I have said before, in mitral stenosis, in which the bigeminal pulse had followed the dropped beat. An old lady, aged seventy-seven, had been to Olympia on Feb. 11th. She was ailing on the 12th and 13th, and prostrate on the 14th, complaining of oppression in the chest and respiratory distress. She

Digitized by Google

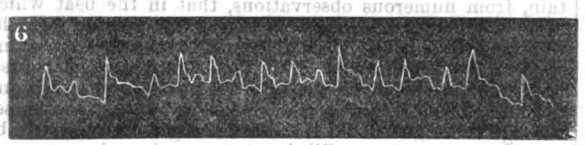
was found to have a pulse of only 35 to 40, instead of 76, and the double heart beat. She improved under stimulant treatment, and when I saw her on the 17th had a pulse of 60 in coupled beats, which were about equal in strength and volume, and followed each other rather quickly, the pause being long enough for two more beats at the same rate. The rhythm was that of common time in music—1, 2, 3, 4; 1 and 2 being beats, and 3 and 4 silent. No cardiac impulse could be felt, but the beats, as followed by means of the sounds, had the same rhythm as the pulse, and there was a systolic mitral murmur with each. A doubtful abortive systole seemed to be audible at times.

A single instance of the pulsus trigeminus may be given. The patient, a needlewoman, aged forty-one, employed in St. Mary's Hospital, had been in better circumstances before taking this situation, and after fifteen months in it was set to do laundry work. Lifting and carrying heavy baskets caused blood to well up into her mouth, but, in spite of this and of feeling weak and languid, she persisted without complaining for a fortnight, when she was sent into the ward on Sept. 14th, 1885. She looked languid, and had from time to time sharp pain in the cardiac region. The pulse was trigeminal, with two distinct and similar beats, and then an intermission, the third beat, however, being very faintly indicated by the sphygmograph. On auscultation of the heart, which was of normal size, a triple rhythm was observed; the first beat gave perfectly normal sounds; the second a good first sound, but a reduplicated second sound at the base; the third beat had no second sound at all, and the first was rather precipitate. A cardiogram taken as well as the sphygmogram by my clerk, Mr. S. A. Tidey, shows the rhythm of the heart. (Chart 5.) As the

patient gained strength the cycle was extended to four and five beats while in bed, but reverted to the trigeminal type when she began to walk about, and it had this character when she returned to her duties as needlewoman. To it seems to me that the cases cited invalidate Tripier's conclusion that the peculiar modification of the cardiac rhythm, in which every other beat is dropped, is always associated with and due to epilepsy, and usually of very serious import; nor can I accept the other conclusion that a slow pulse with epileptiform attacks is always due to dropping of alternate beats. The decision is of importance, since upon it turns the question of whether, as Tripier believes, it is the epilepsy which affects the cardiac rhythm, or whether, as I think, it is the slowing of the circulation which causes the convulsions. Before entering upon any discussion on the subject, however, I may bring evidence to show that there may be a slow pulse with syncopal or epileptiform attacks which is not due to abortive heart beats. I have myself seen a case of fatty degeneration of the heart attended with syncopal attacks, which soon after proved fatal suddenly, in which the pulse was infrequent without any interposed feeble heart beats being detected on careful examination. The patient, however, was seen only once in consultation. The notes of a hospital case, with numerous tracings which I think would have corroborated this, are unfortunately missing.

In THE LANCET for 1885 (p. 288) cases of slow pulse with epileptic seizures are related by Mr. F. St. George Mivart and Dr. A. T. Gibbings. Mr. Mivart's patient was a man aged sixty-one, who had been subject to rapid and violent palpitation of the heart. His first fit was six years before he came under Mr. Mivart's care, and this and most subsequent ones came on while he was stooping. His pulse rate was 24, and there is no record either of interposed weak beats or of abortive systoles. In Dr. Gibbings' case the patient, aged sixty-five, had for some time had an intermittent pulse of about 60. After an attack of bronchitis he suffered from dyspnœa and palpitation, and the pulse was found to be only 44. Still later he became subject to frequent epileptiform attacks, and his pulse had now fallen to 22, but was full and regular, the heart beats corresponding in time. It is noteworthy that the epileptiform attacks would come on when the patient sat up. The pulse continued to fall, and it reached 12 or 13 the attacks being now so frequent that he went out of one into another. The urine also became albuminous. With a subsequent return of the pulse to 31 the albumen disappeared, and he was so much better as to be able to do a little work. While apparently better, he fainted at stool, and died. Nothing abnormal was found either in the heart or in the nervous centres. This patient was seen by Sir Andrew Clark and the late Dr. Moxon, and it is distinctly stated that the heart sounds were normal. We may conclude, therefore, that there were no abortive beats. It is true that it is not expressly stated that they were absent, but in a case of such interest they could not have been overlooked.

The infrequent pulse of fatty heart may fairly be attributed to the structural degeneration of the organ; but an infrequent pulse, when the heart is sound, and especially if it is due to the occurrence of alternate weak beats, can scarcely be explained in any other way than by the interposition of the nervous system. This does not bring us much nearer a true comprehension of the phenomenon, and, as I have already stated, I do not accept the conclusion at which Tripier has arrived, that it is an effect of epilepsy. On the contrary, I look upon convulsive attacks, when they occur in connexion with an infrequent pulse, as a result of cerebral anæmia, produced exactly in the same way as the convulsions after great hæmorrhage. In Mr. Mivart's case the convulsions came on when the patient stooped, in Dr. Gibbings' when he sat up, changes of attitude being sufficient in the extremely feeble state of the circulation to determine such an arrest of the blood-supply to the brain as would give rise to an attack. The late Dr. Moxon, it will be remembered, went so far as to suggest that the initial event in common epilepsy was a stoppage of the heart.



Another question is suggested by some of the cases of dropped heart beat. In almost all, while the aortic second sound of the weaker beat which fails to reach the wrist is absent, the pulmonary sound is audible. In many the impulse and first sound of the right side of the heart are more distinct than those of the left, and occasionally there is such a difference in the situation of the impulse and in the character of the sounds as to suggest that the two sides of the heart are beating alternately; there may even be a mitral murmur with one beat, a tricuspid with the other. The extreme case is met with only in mitral stenosis under digitalis. Now, while it must be taken as demonstrated that there is no such occurrence as an alternating action of the two ventricles, it is certain, from numerous observations, that in the beat which does not raise the aortic valves the systole of the right ventricle is often forcible, and the pulmonary second sound is usually distinct. This last sign means, of course, that blood has been thrown into the pulmonary artery and not into the aorta, and as the amount of blood which passes through the right and left heart in a given time must be equal so long as the equilibrium between the pulmonary and systemic circulation is maintained, the propulsion of blood from the right ventricle only must be supplementary. In mitral stenosis it is easy to understand that such an extra contraction of the right ventricle might be useful in maintaining the pressure in the pulmonary circulation which is necessary in order to force the blood through the constricted orifice; or, regarding it in another aspect, the abortive contraction of the left ventricle is due to its being inadequately filled during one diastole so that a second is needed. No such necessity, however, is apparent when both valves and walls of the heart are normal.

Intermittent and irregular pulse.—With regard to the intermittent and irregular pulse I have nothing to say which will not be familiar to all my hearers. Intermission, occasional or habitual, of the pulse is compatible with health and vigour up to extreme old age, and, in the absence of symptoms, may practically be disregarded. The intermission of the pulse is associated with a hurried and imperfect beat of the heart, of which the first sound is sometimes sharp and following immediately upon the second of the preceding normal beat, at other times it is weak. A weak pulmonary second sound is usually audible. An intermittent pulse may, however, be among the signs of fatty degeneration of the heart, but it will not stand alone. In case of doubt the patient should be made to walk briskly for a minute or two, when the really weak heart will falter, while if the heart is healthy the intermission will usually disappear; it will often disappear also during the administration of chloroform.

Marked irregularity of pulse is most frequently met with in mitral regurgitations; next in dilatation of one or both ventricles; but it occurs independently of any disease of the heart. The fact that it is so commonly associated with incompetence of the mitral valve, while it is rarely observed in other forms of valvular disease, except when the heart is failing, seems to indicate a mechanical rather than a nervous origin of the disturbed rhythm in mitral regurgitation, and it appears to me to be related with the varying pressure upon the heart in respiration. When the mitral valve is incompetent, and the blood can pass back into the auricle as well as forwards into the aorta, the proportion which is driven in one or other direction will be determined by the comparative degree of resistance. Now the dilated left auricle will be supported by a certain amount of pressure during expiration, which will tend to resist distension by the regurgitant blood; but at the end of expiration the conditions are suddenly reversed, and it will be exposed to the negative pressure or suction action which fills the chest with air, so that the reflux is favoured. The sum total of the resistance to the ventricular systole is thus diminished at this moment, and the systole is consequently very rapid, at the same time that less of the blood goes forward into the aorta. At the end of inspiration opposite forces come into play, and the repetition every two or three beats of these disturbing influences quite accounts for the irregularity of the heart's action. In an early stage the irregularity can be seen to occur coincidentally with the end of inspiration and expiration. It is the incompetence of the mitral valve which exposes the ventricle to the respiratory pressure variations; but when, from any affection of the lungs, such as bronchitis and emphysema, the difference between the pressure on inspiration and expiration is greatly augmented, we find the action of the heart disturbed in like manner, and careful watching will show that the chief irregularities coincide with the reversal of the action of the chest.

Irregularity of pulse of nervous origin is illustrated by the disturbance of the cardiac rhythm in dyspepsia and by tobacco; but it may be present in an extreme degree independently of any recognisable influence, and may be habitual. There need be no affection of the general health or impairment of vigour or endurance. In one of the worst cases I have ever seen, the patient, who was for some time under my observation, was, long after the age of sixty, in the habit of addressing public meetings. The trace exhibited (Chart 6) was taken recently upon a gentleman, now aged

seventy, who consulted me twenty years ago on account of irregular action of the heart, and has had it ever since. I am unable to fix any prognostic value on irregularity of the pulse as such; and when it occurs in connexion with dilatation of the heart, the prognosis is determined by other considerations.

I now proceed to the consideration of variations of tension, and I shall first speak briefly of *low tension*.

Tension in the pulse, as has been already stated in the first lecture, depends primarily on the freedom of the flow through the capillary network; and it is low when the capillaries and arterioles are relaxed, allowing the blood to pass readily. As the capacity of the arterial system increases towards the periphery, the branches at each division being collectively larger than the trunk from which they spring, and as the capillary channels are larger still, it is conceivable that the blood might escape as fast as it could be injected by the heart. The actual realisation of this possibility is incompatible with life, as the functional activity of the nerve centres is dependent upon a continuous flow of blood through them, and under the circumstances supposed it would be intermittent. The resistance, however, in the arterioles and capillaries may be so slight that the blood has still a pulsatile movement when it reaches the veins. Such venous pulsation in the veins of the back of the hand can often be demonstrated in aortic regurgitation, but here it is not so much the diminished resistance in the capillaries as the exaggeration of the pulsatile variations of pressure in the arteries which brings it about. In order to see pulsation in the veins, however, the capillaries must be relaxed by putting the hand in hot water, or there must be pyrexial relaxation of the peripheral vessels, which often renders it very evident. Occasionally venous pulsation is met with when there is no heart disease, or any other cause than abolition of the normal resistance in the capillaries. I witnessed it in a gentleman who was gradually sinking from the effects of alcohol without any of the usual alcoholic disease of the liver and kidneys. He took less and less food, and came to live on alcohol, and finally had slight pyrexia and occasional attacks of hæmoptysis. The arteries were large, thin, and soft; and for some time pulsation in the veins of the dorsum of the hand could be rendered visible at any time by dropping the wrist so as to allow the veins to fill.

The characteristic mark of low tension in the pulse is the complete subsidence of all blood-pressure in the artery between the beats. It therefore allows itself to be flattened under the finger in the intervals of the pulsation, and this causes the impact of the pulsation to appear sudden. Further, as we have seen, it must be short. Variations are observed according to the size of the artery and the action of the heart. The artery must be relaxed. When the artery is large and the heart is acting forcibly, we shall have a large, short, strong pulse—the full and bounding pulse of old writers; and dicrotism will usually be conspicuous. When, with a large relaxed artery, the heart is weak, the pulse will be large, short, and weak, still with dicrotism. We cannot have a contracted artery and powerful heart's action with low tension. A feebly acting heart and small artery—the artery being small simply from want of distending force—will give the small, short, weak pulse described as thready; and the absence of a distinct wave of pressure gives it an undulatory character.

One of the most constant effects of pyrexia is to relax the arterioles, and the pulse characteristic of all forms of fever is one of low tension. The pulses above given are, in effect, if also frequent, the pulse of pyrexia in different forms and stages. On these, consequently, I do not dwell. A low-tension pulse in the absence of pyrexia, unless it is a physiological peculiarity of the individual (and it may be remarked, in passing, that a pulse of a very low tension may run in families) is indicative of debility. It may go so far as to suggest the existence of fatty degeneration of the heart, except that the pulse of cardiac weakness is usually frequent, while that of fatty decay is more commonly under the average rate. The heart sounds also are weak and short. The symptoms associated with a pulse of low tension are extremely varied, and they are for the most part not the result of the weak pulse, but concomitant effects of a common cause. Many of them are equally common when the pulse tension is high, and the question is not what symptoms arise out of low or high pressure in the arteries, but, given certain symptoms, what is the state of arterial tension, since this will be an important guide in the treatment. When the tension is low, purgatives are badly borne, and mercurial aperients give rise to great depression. Sometimes, indeed, the subjects of low arterial tension feel much better when the bowels are constipated, and exhausted after each action. There are no doubt cases in which the chief cause of deficient pressure in the arteries is want of functional vigour in the heart, and it would be of service to be able to distinguish such cases from those in which the primary cause is absence of resistance in the arteries and capillaries, but this is not easy. A low state of arterial tension is not in itself a source of injury to the heart or vessels. It has an important bearing on affections of the nervous system; but questions relating to this are reserved for the third lecture.

High tension.—The cause is obstruction to the free flow of blood through the minute arterioles and capillaries to the veins. There is some difference of opinion whether the exact seat of this obstruction is in the arterioles or capillaries. It is probably not in all cases the same. In high arterial tension of purely nervous origin—as, for example, in hysteria, in cerebral and spinal disease, in rigor and the cold stage of fever—there can scarcely be any question that the cause is tightening up of the minute arterioles; but in tension of blood origin—as in renal disease, gout, and allied conditions—it seems to me that the primary obstruction is in the capillaries, contraction of the arterioles being no doubt associated with this, but secondary to it, either by way of continuity, or as a defensive counteraction against the distending internal pressure set up by the obstacle beyond. I

Digitized by Google

may briefly enumerate some of the reasons which have led me to this conclusion. The most important are derived from an examination of the minute arterioles in the brain after death resulting from contracted granular disease of the kidney. When there have been uræmic convulsions, capillary hæmorrhages are almost always present in various parts of the cortex, so much so that our late distinguished colleague, Dr. Mahomed, attributed the convulsion to capillary rupture. If the capillaries were protected by contraction of the arterioles, such rupture could scarcely occur. Again, these arterioles are themselves at certain points dilated into miliary aneurysms, and liable to rupture, not where they are given off from larger branches, but just where they break up into the capillary network, which shows the obstruction to have been beyond, and not in, the arterioles; while not only are the perivascular spaces round them large, as if from distension, but a ring of the surrounding brain substance is pale, as if from pressure. Another reason is that although the medium-sized arteries (such as the radial) and the small arteries (such as the digital) are usually contracted and small in high tension, this is not always the case, and it seems improbable that in vessels anatomically continuous and physiologically correlated there should be contraction in the minute arterioles without a corresponding condition of the arteries leading to them. In further support of this view I may cite the important experiments of Drs. Ringer and Sainsbury on the action of the digitalis group of remedies (Med. Chir. Trans., vol. lxvii.). It is there shown that when all reflex contraction of the arterioles is rendered impossible by destruction of the brain and spinal cord, digitalis and other substances having similar properties give rise to marked diminution of the flow through the arterio-capillary channels. The action is thus proved to be direct upon the contractile structures of the capillaries and arteries, and not indirect through the vaso-motor nerves.

I must, at the risk of tedious repetition, again describe the high-tension pulse. Its distinguishing characteristic is that the artery is full between the beats. So full is it that it can be rolled under the finger as if it were a tendon, and followed like a solid cord some distance up the forearm; and, when the tension is well marked, no pulsation may be felt while this is being done, unless decided pressure is made by the fingers. Above the wrist, when the artery rests upon the muscles of the forearm and not on the radius, it may be difficult to detect pulsation. Not unfrequently, especially when the skin is thin, the artery can be seen to form a distinct projection, but no pulsation is visible in it, unless it is thrown into a curve, when this will be seen to be accentuated at each beat. The artery is usually small from contraction of its muscular coats, unless it has been dilated by protracted distension, when it may have much beyond the average diameter. When pressure is applied in order to bring out the character of the beat, it is found that this does not strike the finger sharply, but rather lifts it powerfully; it persists for an appreciable time, and then gradually subsides with little or no dicrotic echo. It is the long pulse, "pulsus tardus." The size of the vessel will make some difference in respect of all these points; the distinctive features are best marked when it is small; when it is large, both the incidence and the subsidence of the pressure will seem to be more abrupt, especially if the artery is thoroughly flattened by the fingers. With moderate compression the beat feels less sudden, and has the gradual rise, sustained duration, and slow decline which is characteristic of high tension. Another character of the high-tension pulse comes out when its strength or force is tested by attempting to arrest the beat. While the fingers rest lightly on the vessel, little pulsation is felt; but as pressure is employed, the more forcible does it seem to be; and when the artery is greatly contracted, it is really difficult to extinguish the wave.

While the prime cause of high tension in the pulse is obstruction in the peripheral circulation, the actual pressure in the arteries is maintained by the heart. Usually the increased difficulty in driving on the blood is met and counteracted by increase of the contractile energy of the heart; but it is clearly possible that while there is obstruction in the arterioles and capillaries the heart may not rise to the occasion. We shall then have, in feeling the pulse, an artery full between the beats and capable of being rolled under the finger, while at the same time it is compressible. This is, in fact, very common, and we require a term which may be applied to such a condition. I have been in the habit of speaking of it as virtual tension. Now, as the artery allows itself to be flattened, the pulse wave which lifts it into the cylindrical form appears to be sudden, and the pressure, after lasting a certain time, seems to drop suddenly. The artery may be small or large, and the pulse varies accordingly.

We meet with the conditions which give rise to virtual tension at the two extremes of kidney disease. At the outset of acute renal dropsy, while there is obstruction in the arterioles and capillaries, the heart is rendered weak by the pyrexia and low diet, and there is more or less tendency to it throughout the attack. Again, as the heart becomes worn out in the course of chronic granular disease of the kidney, it ceases to be capable of maintaining the high tension which is characteristic of this disease, and virtual tension takes its place. It is at this period that reduplication of the first sound is so well marked. The same course of events is observed after protracted high tension from whatever cause; and as this is the origin of dilated left ventricle, the pulse of virtual tension, in its best marked form, comes to be the characteristic pulse of dilatation of the heart. At the same time that it is expanding the left ventricle, the continued obstruction in the arterioles and capillaries is overcoming the contractile power of the medium-sized arteries, the lumen of which becomes enlarged, while their coats are thickened.

The causes of high tension are now so generally recognised that I shall do little more than enumerate them. They are as follows:—1. Hereditary. This is illustrated not only by the every-day experience that paralysis and heart disease run in families irrespective of the habits and mode of life of different members, which may differ greatly, but by the fact that high pulse tension and functional derangements arising out of it may be present in childhood and all through life in every member and in successive generations of many families. 2. Kidney disease of all kinds, except such as is attended with suppuration; but the most marked tension is met with in the contracted granular kidney. 3. Gout and allied conditions, including almost the entire range of affections attributed by Murchison to functional derangement of the liver. 4. Lead-poisoning, with or without renal disease or gout. 5. Anæmia. It is not easy to understand how anæmia can give rise to high tension in the pulse. One would have expected the watery blood to pass readily through the capillaries and the *vis a tergo* applied by the heart to be deficient, but it is a matter of daily observation that the artery is full between the beats, and that the pulse, if more abrupt than in renal disease, is long. It has been conjectured that the defective oxygen-carrying power of the corpuscles may cause oxidation to be imperfect, and so lead to the formation of substances which are not readily eliminated, and which provoke resistance in the arterioles and capillaries; but the instability of the tension is suggestive of the intervention of nervous influences, and there are other peculiarities which lend support to the hypothesis that the arterial contraction and powerful heart action may be vaso-motor phenomena. However this may be, there are rare and exceptional cases of anæmia with extremely low tension, and it has been an object of attention with me to make out whether any constant difference of another kind attends this difference in the state of the circulation. In particular, it seemed probable that there might be some influence on the production of hæmic murmurs which might throw light on their causation, especially from the point of view of Marey's theory, which refers all cardiac murmurs to low pressure beyond the point at which the vibration is set up. Up to the present, however, I have been unable to recognise any distinction between anæmia with high tension and anæmia with low tension, except the difference in the circulatory conditions. 6. Pregnancy. 7. Constipation. 8. Plethora—an overladen state of the entire vascular system. 9. Chronic bronchitis and emphysema.

The effects of high tension upon the heart are easily understood: the high blood-pressure in the arterial system calls for increased contractile energy on the part of the ventricle, in order that it may overcome the pressure and carry its contents into the aorta. If the resistance with which the heart has to contend is augmented gradually, it will respond by hypertrophy; if, however, the increase in the resistance is sudden, the heart will be unable to complete its systole and expel the whole of its contained blood. Dilatation is then the result, and it will take place all the more readily if the nutrition of the heart is interfered with. Dilatation of the left ventricle may result from high arterial tension at almost any period of life, and is met with under

Digitized by Google

a great variety of circumstances. It is very common in anæmic girls, and is frequently attended with mitral regurgitation, which is curable, as has been well shown by Dr. George Balfour. Some contributory exciting cause will be traceable. I have known it to be due in several instances to hunting, in others to lawn-tennis, in others to much walking up-hill. In one case recovery only took place when the family of the patient left a house in an elevated situation which made every walk terminate in a climb. While curable if taken in time, the dilatation of anæmia often establishes permanent heart disease. Acute dilatation, which is of far more frequent occurrence than has been supposed, has for its predisposing cause peripheral resistance in the circulation and high pressure in the arteries. It may take place in the course of acute disease, or as a sequel, if the pyrexia has not neutralised the habitual tension by relaxing the arterioles. It may, again, be produced either by too violent or by too protracted exertion, and this at almost any time of life at which high tension is common. The gradual dilatation which occurs with varying degrees of antecedent hypertrophy in chronic gout or renal disease, or as a result of chronic resistance to the circulation, from whatever cause, need only be mentioned. Valvular changes, mitral and aortic, and the dilatation of the aorta, are also so familiarly referred to high tension that they require no further notice, and the same may be said of cerebral hæmorrhage.

One word may be permitted on the injurious effects of peripheral resistance in aortic or mitral regurgitation. In both these valvular lesions high tension, or rather the tendency to this condition, is disguised by the effects of the regurgitation, and is liable to be overlooked. Actual tension, as manifested by sustained fulness of the artery between the beats, is indeed impossible in aortic regurgitation, since the fulcrum is wanting, and it is not easily recognised in mitral regurgitation. The subjects of such lesions, however, may be gouty or may have renal disease, and the peripheral resistance incident to these affections will not be suspended. The injurious tendency of this resistance will be manifest at once. The greater the force required to drive the blood through the capillaries, the greater will be the force with which it will be driven back through a leak in the mitral valve, and the more powerful the dilating effect on the left ventricle when the protection of the aortic valve is lost. The prognostic bearing of such an influence in the early stages of these valvular diseases makes it important that it should be recognised, especially in the young, when treatment may do much to avert the evil consequences. In aortic insufficiency an idea may be obtained by careful examination of the pulse when the hand is well below the level of the shoulder and of the heart; it should not hang down, as it is then difficult to distinguish between the persistent fulness due to the weight of the column of blood and that due to the obstruction in the capillaries. In mitral regurgitation it will be sufficient to bear the question in mind, and to examine the pulse in different positions of the hand. Information may also be obtained from an examination of the pulse of other members of the family.

In connexion with the subject of renal disease and gout and high pulse tension, I must find an opportunity for calling attention to the fact that cases are met with in which the tension is altogether absent, and this not because the heart is weak or failing, but because there is even less than the normal resistance in the arterioles and capillaries. The prognosis when such is the case is extremely unfavourable. It is in connexion with the chronic, large, white kidney that we most commonly see a weak, soft, low-tension pulse with albuminuria. The amount of albumen is often very great; it varies from day to day, often without traceable cause, but often, again, it is increased by exertion or mental depression, or constipation, and it is usually greater at night than in the morning. Any development of tension in the pulse is attended with diminution of the albumen. The patient may not have the least appearance of kidney disease, and dropsy may be entirely absent. Tension, again, may fail to supervene in acute albuminuria, and when such is the case, a fatal result is, according to my experience, always to be expected. I have come, indeed, to take the development of high arterial tension as one of the chief guides in prognosticating the course and issue of this affection; if it makes its appearance early, and becomes well marked, the prognosis is favourable; there appears to be an increased liability to uræmic convulsions, but the patients bear the treatment required by this and other complications, and usually recover. If the tension is slowly developed, and especially if it is fitful and inconstant, the recovery is slow and uncertain, while, as has been said before, if the pulse remains soft, short, and weak throughout, the prognosis is bad. Dropsy is usually considerable, and there is often an unusual amount of blood in the urine, as well as casts.

In contracted granular disease of the kidney absence of tension is very rare, and I have no record of a well-marked instance in which the diagnosis has been verified post mortem. In the following case I had no doubt as to the nature of the case during life. The patient, aged about fifty-five, was under my observation from time to time from June, 1880, up to his death in September, 1881. He had suffered from gout and eczema, and when I first saw him albumen had just been discovered in his urine, which had a specific gravity of 1011. He had always lived freely, and could not be prevented from taking a considerable amount of whisky. His eczema was removed and his gout relieved, and he usually looked and felt well; the quantity of urine was not far from normal, and the specific gravity usually varied from 1017 to 1021, while a mere trace of albumen was present; and it was only the knowledge that he had albuminuria which induced him to present himself. He was well nourished, had a good colour, and a largish, soft, short pulse; there was no evidence of degeneration in the walls of the vessels, nor any change in the heart. When the shooting began in September, 1881, he went out as usual, but was more easily tired, and took extra whisky to enable him to go on. On the 14th and 15th he said queer things at dinner. On the 15th Mr. Martin, of Crawley, saw him, and found him languid and sleepy. After a jalap powder he was better, but in the night of the 17th he was seized with violent convulsions. I saw him with Mr. Martin at 1 P.M. on the 18th, when he was lying on his left side, the left side of his face boring into the pillow, his eyes directed violently to the left, the left arm bent across the chest, with the hand up at the right shoulder, pulling violently at the night-shirt, which was torn. He was smacking his lips loudly. These movements came on in paroxysms, but with such short intervals as to be almost continuous. The left leg was very little affected. Sensation was very greatly impaired in both arm and leg, and might be said to be lost. He was conscious and intelligent, and in the intervals between the paroxysms could direct his eyes to the right, and could give either hand. The convulsions continued, except when he slept, and in the course of the 19th deglutition failed, the breathing becoming deep and loud, and death by coma supervened. I have entered into these particulars to show that the convulsions were not of the ordinary uræmic character. They were clearly due to cortical irritation, but no post-mortem examination could be obtained. The case is quoted to illustrate the position that absence of arterial tension, where such tension is a part of the disease, is not a favourable sign. The patient had not the look of kidney disease; he was well nourished, and had a good colour; the heart gave no evidence of disease, and the arteries were soft and flexible; the high tension which predisposes to rupture of cerebral arteries was absent; there was nothing, in fact, suggestive of impending danger.

Functional effects.—Without recognisable organic change in the heart or arteries, or where the subsequent history shows that such changes as were present were not of themselves the cause, high tension may give rise to the most severe angina pectoris. High tension, again, may produce effects in the way of breathlessness and sudden powerlessness which simulate the effects of the most advanced heart-disease. Intermittent functional albuminuria, when not traceable to imperfect assimilation of food, is, so far as it has come under my observation, associated with high pulse tension, and is most readily amenable to treatment which reduces arterial pressure; and the cases of this affection, described by Dr. Clement Dukes of Rugby, and shown in his admirable papers on the subject to be common among boys and adolescents, appear to belong to the same class as mine. When this liability to the appearance of albumen in the urine on exertion or slight exposure is met with in children, I have always found a strongly neurotic family history, as well as hereditary high pulse tension. When it does not come on till the approach of adolescence, there may be no family neurosis, but I have never failed to recognise tension, and to trace its effects in other members of the family.

Treatment.—Although high arterial tension is fraught

Digitized by Google

with so many evil contingencies, it is not to be looked upon as *hostis humani generis*, and attacked whenever found. I have already stated and exemplified by cases that, supposing renal disease or gout to exist, the prognosis is unfavourable if the pulse tension is not high. This is equivalent to a declaration that under such circumstances the high pressure in the circulation serves some useful end. We do not, therefore, treat tension as such, unless it is actually causing suffering, or doing present or prospective harm. For the most part, indeed, the object of our treatment is to remove the condition on which unduly high tension depends.

Among the measures for the reduction of tension, one of the most potent is bleeding. This is usually practised only in extreme cases, and when it is employed it is as a remedy for the high tension itself, or for some of its more serious and dangerous effects, such as convulsions. When cerebral hæmorrhage has occurred it is too late to bleed; but were high tension in the pulse more closely studied, and were less attention paid to the public prejudice against vene section, it would be anticipated and prevented in hundreds of cases every year. Physiological experiment seems to throw doubt on the production of a rapid diminution of pressure in the arteries by bloodletting, but there can be no question as to the effect in the mind of anyone who has practised venesection in a case of uræmic convulsions. The results are more than can be easily attributed simply to the withdrawal of so much blood. In acute nephritis, when bleeding has been necessary because of convulsions, I have more than once seen unaccountably rapid disappearance of the albumen from the urine, and complete recovery. The statement made by trustworthy observers, when bloodletting was common, that at times patients could not be got under the influence of mercury until they had been bled, and that then salivation was induced at once, is evidence of some profound change in the system; possibly a more rapid absorption resulting from the diminution of intra-vascular pressure may enter into the explanation, and the taking up into the blood of fluid effused into the cerebral meninges or ventricles. The spring and fall bleeding of our forefathers must have been a great relief to many of those upon whom it was practised, and in some I have no doubt it prolonged life. I have had under my care from time to time an old lady, the only clue to whose age is the fact that her father, who was a historical character, died in 1803, who had been bled fifty times, first for puerperal convulsions and for their prevention afterwards. The punctures at the bend of the elbow had been so numerous that there was no room for more, and the later bleeding had been done from a vein in the foot. I do not think the old lady would have been living now but for the bleeding. When I last saw her, about two years since, she was managing the family of a deceased daughter. All her children are dead; the last, a daughter, who was the only one I saw, died from chronic Bright's disease; her grandchildren by another daughter, who died in childbed, are the subjects of high tension.

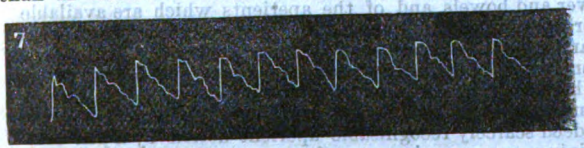
Apart from bleeding, tension can be lowered by reducing either the force of the heart or the resistance in the periphery. The former method can be called for only in some emergency, such as threatened cerebral apoplexy, and, if employed, will lay the heart open to dilatation, unless the obstruction with which it is contending is also removed. The latter is the chief indication to be followed, and it can be met in two ways: either by drugs, which relax the minute arterioles—such as amyl-nitrite, nitro-glycerine, and the nitrites; or by modifying the blood condition, which provokes the obstruction in the arterio-capillary circulation. The remedies which relax the arterioles are invaluable where either there is active arterial spasm, which is of itself a cause of pain and danger, as in angina pectoris, or when the contraction of the arterioles, without being abnormal in degree, is contributing to overpower the heart. They may thus be of service in high tension of renal origin, and are said to have contributed to the cure of diseases of the kidneys. I have administered nitro-glycerine repeatedly in different forms of renal disease, but without any other effect than temporary relief of some of the symptoms, and improvement in the patient's appearance from the admission of more blood to the pallid surface. I am quite prepared to believe, however, that continued diversion of blood from the diseased organ, which will be one effect of the general relaxation of the arteries, may favour their return to a normal condition.

The blood condition which gives rise to tension I have already stated to be, in my opinion, the presence in it of some form of impurity, and for the most part nitrogenised waste. The treatment demanded, then, is simply elimination. When the cause of this is disease of the kidneys or liver, the primary object of the treatment will be its cure; but side by side with this, and often, indeed, forming a part of it, will be required measures for the removal of the matters which are retained in the blood in consequence of the suspension of the functions of these organs. Any or all of the eliminating organs and surfaces may be made use of. In certain cases free perspiration is useful. While, however, the altered distribution of the blood which is brought about by the means taken to induce perspiration, such as the Turkish bath, and its determination to the surface of the body, is often of service, the cutaneous excretion is chiefly water, and no great amount of organic matter is carried away, except in kidney disease, when an efflorescence of urea may be found on the surface after a copious perspiration. According to my experience, elimination by the skin is rather an accessory than a primary means of keeping down tension. The kidneys are capable of carrying off a much larger amount of nitrogenised waste than the skin, and diuretics may in this way contribute to the relief of tension. But many diuretic remedies give rise to tension, and apparently produce their effects by raising the blood-pressure. The elimination desired for the purpose we are now considering is best obtained by the diuretics, which promote tissue change and oxidation; by copious draughts of pure water night and morning, which will wash out the tissues and carry off any soluble matters; and by potash and lithia, which are solvents of uric acid. It is not altogether a matter of indifference what salts of these alkalies are used; the citrates can be taken in larger doses, and they will render the urine alkaline quite as easily as the carbonates if this is desired; but the carbonates appear to have more metabolic influence, and liquor potassæ has a still greater effect of this kind. The elimination which has the greatest effect on arterial tension is that from the liver and bowels, and of the aperients which are available for the production of purgation the most efficacious for this particular purpose are such as contain mercury. This is a conclusion based entirely on experience and observation. Whether as regards relief of symptoms associated with high tension or as regards the effect on the pulse, a moderate and indeed scarcely recognisable aperient action by a pill containing mercury in some form or other is much more efficacious than free purgation by other means, and pills of this kind can be taken once or twice a week for years in suitable cases with advantage.

The pulse in heart disease has been so thoroughly studied, and is so frequently and fully described, that I shall treat it very briefly, and I only refer to it at all in order to insist on the necessity of taking it into account in both the diagnosis and prognosis of affections of the heart. It is not every systolic murmur at the right second space that indicates obstruction of the aortic orifice, and if we must admit that a systolic apex murmur is proof of some mitral reflux, the murmur tells us absolutely nothing of its amount. The pulse must be brought in to interpret the murmur and fix its significance.

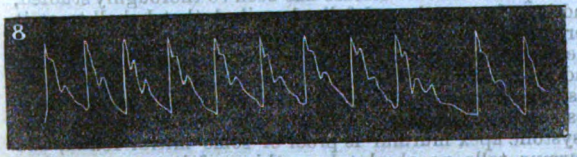
Aortic stenosis.—The effect of narrowing of the aortic orifice is obviously to intercept the pressure of the ventricular systole and retard the current, and, as the blood cannot gain in pressure or speed, the pulse must be gradual and long. But, besides this, the entire arterial system seems to contract down upon the diminished blood stream, and the pulse is also small. One does not see altogether why, with normal resistance in front, the arteries should not be kept at the usual size by the pressure from the heart, because this pressure takes effect more gradually; but the small diameter of the radial and other arteries is a constant phenomenon, and the pulse of aortic stenosis is, when well marked, one of the most peculiar met with: small, full between the beats, and destitute of anything like impact.

Aortic regurgitation.—The pulse of aortic regurgitation is too well known to require any description. I would only call attention to the element of size in the arteries as important, to the necessity of ascertaining carefully whether the column of blood is at all sustained in the radial when the arm is held up, or whether the blood drops out of the vessel immediately the ventricular pressure is withdrawn, and to the extraordinary influence of pyrexia in exaggerating the collapsing character of the pulse. The slightest departure



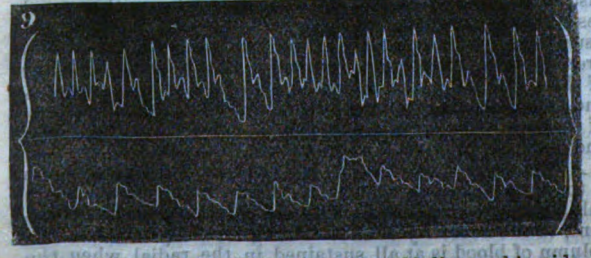
Digitized by Google

from regularity in the collapsing pulse is ominous; when this takes place, it is due at first to an occasional faltering beat, and it rarely reaches any considerable degree.



Mitral regurgitation.—The irregular pulse of mitral incompetence has already been alluded to. It is by no means constantly met with when a mitral regurgitant murmur is audible; and while it indicates, when present, decided impairment of the functional efficiency of the valves, with secondary effects arising out of this, I am not prepared to assert that irregularity of pulse is an absolutely necessary consequence of even large regurgitation, nor does it always indicate a dangerous failure of compensation.

Mitral stenosis.—In mitral stenosis the pulse is regular, small, and full between the beats. The contracted state of the arteries is probably due to the arterial system accommodating itself to the restricted output of the ventricle. The regularity of the pulse in this form of valvular affection has been called in question, but, in the absence of associated mitral regurgitation and of considerable secondary regurgitation at the tricuspid, it is maintained up to a very late stage of the disease. When from pulmonary complications or failing adjustment regularity is lost, the first deviation is in strength of pulse, not in rhythm; then beats fail to reach the wrist, and the pulse is irregular, while the heart is acting regularly. Finally, the regularity may defy description, and there is apparently no correspondence between the pulse and the heart, and when both are felt simultaneously, they might belong to a different person.



The pulse of hypertrophy of the heart is that of its cause, and no more need be said of it. The pulse of dilatation has already been described under the head of virtual tension. A number of sphygmograms from cases of dilatation of the left ventricle are given, but they convey a very inadequate idea of the characters of the pulse as recognised by the finger. Scarcely even in aortic regurgitation can the state of the heart be foretold from the pulse more definitely than in dilatation. The first trace (Chart 7) is from a

case in which acute dilatation with hæmoptysis had occurred from over-exertion; a mitral systolic murmur remained; the artery was not large. In the case from which the second was taken (Chart 8) there were breathlessness, difficulty of

lying down, and enlargement of the liver, all of which were relieved by treatment. The patient, whose pulse is represented by the third, was liable to stagger and even fall on rising from a semi-recumbent position, with momentary loss of consciousness, and on slight exertion he would suddenly lose all power. The artery was always full between the beats, notwithstanding the appearance of the trace. (Chart 9.) He improved under treatment, could walk

eight miles, was more cheerful, and could lie on his side; the pulse gave the second trace. Later over-exertion aggravated the dilatation, and thrombosis of the left middle cerebral artery occurred, the case ending fatally.

Lectures ON THE SURGICAL TREATMENT OF PULMONARY CAVITIES.

Delivered at the Consumption Hospital, Brompton,

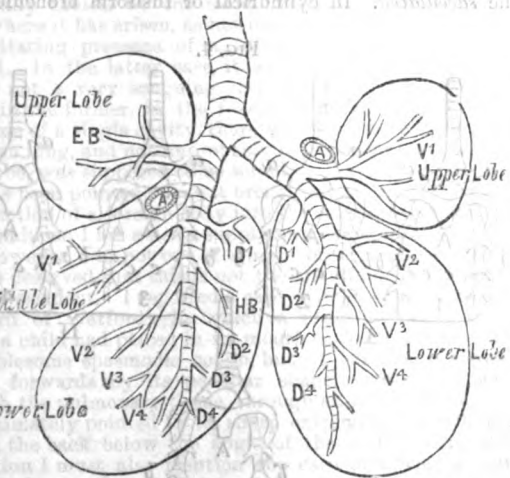
BY RICKMAN J. GODLEE, M.S., F.R.C.S.,
SURGEON TO THE HOSPITAL AND TO UNIVERSITY COLLEGE HOSPITAL.

LECTURE II.

GENTLEMEN,—Before proceeding to the discussion of the next class of cases, and as an introduction to the subject, I wish to offer a few remarks on the anatomy of the bronchi. One of the best, if not quite the best, work upon the subject is that of the late Dr. Aeby of Berne,[1] who deals with the arrangement of these parts with almost more than German exactness. He points out that what is known as the dichotomous branching of the bronchi does not really take place, but that the main bronchus passes through the organ as far as its lowest limit in the contracted part between the diaphragm and the spine (Fig. 3). The arrangement of the arteries and veins to the bronchi is really symmetrical on the two sides—viz., the main branch of the pulmonary artery crosses the principal bronchus at a perfectly definite point on the outer side (Fig. 2, A A) in order to pass downwards behind it, whilst the principal veins keep to the anterior aspect. The

FIG. 1.

Diagram illustrating subdivision of a bronchus, viewed from the back. (After Aeby.) E B, Eparterial bronchus. D and V, Its dorsal and ventral subdivisions. D_1 D_2, Dorsal hyparterial branches, V_1 V_2, Ventral hyparterial branches. *d v*, Accessory branches. P A, Pulmonary artery. P V, Pulmonary vein.



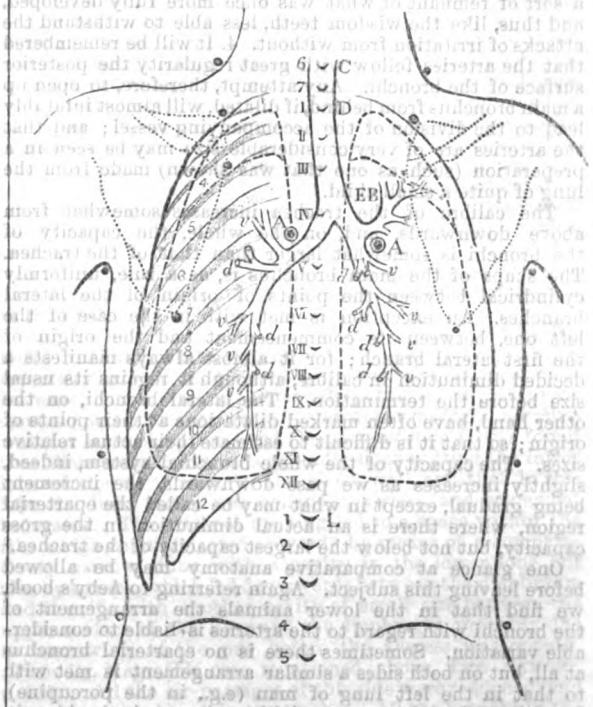
branches of the bronchial tree come off on the dorsal and ventral sides, and are on the whole symmetrical, with these exceptions:—On the right side, one, the first lateral branch, comes off above the point where the artery crosses the main bronchus (Fig. 2, E B), and is hence called *eparterial*, as opposed to the others, which are called *hyparterial*. This eparterial bronchus goes to the upper lobe of the right lung, which thus is the additional element on this side; for the second lateral branch on the right side, which goes to the middle lobe, corresponds to the first lateral branch on the left side, which goes to the upper lobe (Fig. 2, V_1 V_1), and thus the right middle lobe corresponds to the left upper lobe. This unsymmetrical arrangement has also given rise to the common belief that the right bronchus is shorter than the left. Actually the part of the right bronchus which corresponds to the so-called bifurcation of the left is the point of origin of the first hyparterial branch. The hyparterial system is always bilaterally symmetrical, the branches being arranged in two series—ventral and dorsal (Fig. 1). There are four large

[1] Der Bronchialbaum der Saugethiere und des Menschen. Leipzig, 1880.

Digitized by Google

ventral bronchi, beyond the lowest of which the main stem ends in small irregular lateral branches. The dorsal branches present no special features, except that they are small and more deeply placed than the ventral. Accessory branches are met with here and there which do not arise only from the lateral aspects of the main stem. The first of these alone is of much interest; it is of large size, and from its position is called by the Germans "Herzbronchus," or heart-bronchus (Fig. 2, H B). In the ourang-outang and the chimpanzee it resembles the corresponding structure in man and in many of the lower animals it supplies a distinct fourth or azygos lobe. In man the lateral bronchi, especially the ventral ones, are so large that the appearance of dichotomous subdivision is closely simulated, the main trunk often losing half of its previous calibre after giving off a lateral branch. The accompanying figure shows diagrammatically the relation of the bronchus to the vessels and also the typical arrangement of the lateral branches. (Fig. 1.) It will be observed that while in the hyparterial region the dorsal and ventral branches come off separately, in the case of the eparterial bronchus they come off as one trunk. This scheme obviously only holds good in man for the right side. Fig. 2

FIG. 2.



A A, Pulmonary artery. E B, Eparterial bronchus (right side only). V_1 V_2 V_3 V_4, Ventral hyparterial bronchi (right and left). D_1 D_2 D_3 D_4, Dorsal hyparterial bronchi (right and left). H B, Heart bronchus. (Modified from Aeby.)

shows the differences on the two sides, and illustrates the correspondence of the left upper with the right middle lobe. The direction of the main bronchi is not straight, but curved, the convexity corresponding apparently to the outline of the heart. It is a simple **C** shape on the right side, but on the left forms a distinctly **S**-shaped curve, on account of a very marked bend to the left above the origin of the first lateral branch, which indeed causes an actual concavity to the left at the commencement. The amount of the divergence is not by any means constant, varying with the condition of the heart, and being much less in newly born infants than in adults. Generally another curve is also present in the sagittal or antero-posterior direction, the concavity of which is directed backwards. Dr. Aeby made a number of observations to determine the relative divergence of the two bronchi, and (as a fresh illustration of the fact that even the science of anatomy is often led astray by the traditions of antiquity) he demonstrates clearly that the right bronchus follows much more closely the line of the trachea than the left—in some cases, indeed, approaching it very nearly. It is an observation which I have frequently verified. This is an interesting justification, so to speak, of the almost invariable rule that foreign bodies find their way into the right and not into the left bronchus. The error seems to have arisen partly because in the ordinary method of preparation the natural conditions are not maintained, and partly because the higher position of the right lung naturally suggests a similar condition of the corresponding bronchus. I imagine the apparent shortening of the tube by the irregular origin of the eparterial bronchus has also something to do with it.

I have made some dissections, with the help of my friend Mr. Charles Stonham, to show the exact position of the main bronchi as they would be marked on the surface of the body. The trachea has been sometimes injected with plaster-of-Paris, sometimes not, and then, the body being turned on its face on a board, long skewers have been passed in the spots indicated by dots on the diagram (Fig. 3), some round the edges of the subject; two on each side being driven right through the body opposite the angles of the scapulæ, and two others at the vertebral borders of those bones opposite the spines. In this way a tracing of the body was easily made. The soft parts were then turned aside, and the exact outline of the thoracic walls was obtained. The ribs were then partially removed, being cut close to the vertebræ, and also about half-way between the sternum and the spine. The outline of the lungs was then taken, and lastly the bronchi were dissected out *in situ*. The subjects have not been very good, and the results therefore not what one would have wished, but they bring out one or two points of interest. In the first place, the figure shows (and we thought this was perhaps a new point, but find that it is noticed as long ago as the time of Cruveilhier) that the trachea tends slightly to the right, and bifurcates a little to the right of

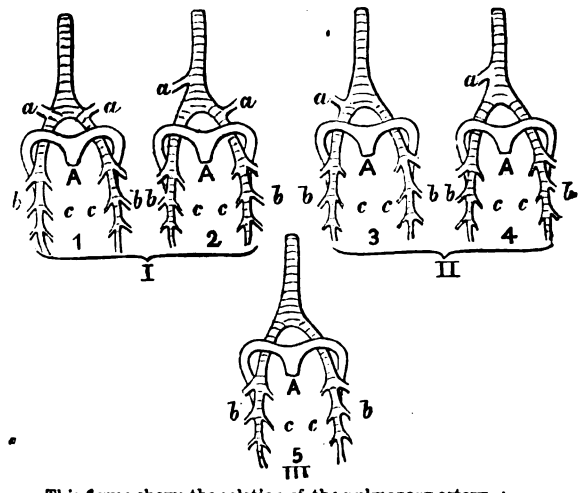
FIG. 3.

Dissection to show the position of the main bronchi. The vertebræ and the ribs are marked by figures. The black dots indicate the position of the pins introduced to mark the outline of the body &c. E B, Eparterial Bronchus. *v v*, Ventral branches. *d d*, Dorsal branches.

the middle line—a fact which makes the almost vertical right bronchus very nearly an exact continuation of the main stem; in the next place, it shows that the bifurcation is opposite or a little below the fourth dorsal spine—that is, a very little below the position of the inner end of the spine of the scapula; and, lastly, it indicates how very near the middle line the main bronchus is in its descent. The exact distance of the main bronchus from the surface we were unable to measure, but on examining Braune's plates it appears to be at the bifurcation of the trachea rather over three inches and a half; opposite the fifth spine rather under three inches and a half; and opposite the seventh spine rather under three inches. These numbers are likely to be rather below than above the estimate, as the subject from which the plate was drawn was a small one, and had been flattened from lying on the back.

The practical outcome of these anatomical facts is, I think, not inconsiderable. 1. As regards foreign bodies. If they are of any considerable size—such, for instance, as the piece of mutton-bone or the tooth which I now show you—it is probable that they will lodge somewhere in the main

Digitized by Google



bronchus of the right side—that is, at a distance not greater than three inches from the middle line. This may be a piece of knowledge of great value in directing an instrument, such as a pair of forceps or a loop of silver wire, down the bronchus with the object of fishing up the foreign body, and it is clearly of importance if attempts are to be made to extract it from behind. In a case to be mentioned later on, we were always so far out in our investigations that our chance of finding the foreign body, which was a tooth, was absolutely *nil*. 2. As regards bronchiectases. They have not, perhaps, a very direct bearing, because, though it will be noticed that in the case of dilatation of the bronchi following on the presence of foreign bodies the main trunks are generally involved, still, both in these cases and in others, smaller peripheral bronchi often serve as the starting-points for excavations of considerable size. 3. As to the development of phthisical cavities one can at present only speculate. It is doubtful, to begin with, whether the right apex really suffers more or less than the left. But the suggestion that it does, and the fact that it certainly appears to differ from other parts of the lung in its liability to gangrene, suggest the possibility that its large vertical feeding bronchus may possibly prevent the accumulation of septic secretions in it. Again, the question arises whether the lobe is a sort of remnant of what was once more fully developed, and thus, like the wisdom teeth, less able to withstand the attacks of irritation from without. 4. It will be remembered that the arteries follow with great regularity the posterior surface of the bronchi. Any attempt, therefore, to open up a main bronchus from behind, if dilated, will almost infallibly lead to the division of the accompanying vessel; and that the arteries are of very considerable size may be seen in a preparation (such as one that was shown) made from the lung of quite a small child.

The calibre of the trachea increases somewhat from above downwards, and, on the whole, the capacity of the bronchi is somewhat larger than that of the trachea. The shape of the main bronchus is, as a rule, uniformly cylindrical between the points of origin of the lateral branches. An exception is met with in the case of the left one, between its commencement and the origin of the first lateral branch; for it almost always manifests a decided diminution in calibre, although it regains its usual size before the termination. The lateral bronchi, on the other hand, have often marked dilatations at their points of origin; so that it is difficult to estimate their actual relative sizes. The capacity of the whole bronchial system, indeed, slightly increases as we pass downwards, the increment being gradual, except in what may be called the eparterial region, where there is an actual diminution in the gross capacity, but not below the largest capacity of the trachea.[2]

One glance at comparative anatomy may be allowed before leaving this subject. Again referring to Aeby's book, we find that in the lower animals the arrangement of the bronchi with regard to the arteries is liable to considerable variation. Sometimes there is no eparterial bronchus at all, but on both sides a similar arrangement is met with to that in the left lung of man (e.g., in the porcupine). Sometimes there is an eparterial bronchus on both sides, in which case they may come off symmetrically (e.g., in the horse); or the right eparterial bronchus may come not from the bronchus but from the trachea (e.g., in the dolphin). In another type, on the other hand, which seems to be the commonest, there is an eparterial bronchus only upon the right side, in which case it may be bronchial (e.g., in man) or tracheal (e.g., in the sheep). It is probable that some symmetrical form is the original type; but whether with or without the eparterial bronchus, and whether this was tracheal or bronchial, we have not yet evidence enough to say. It is remarkable, however, that, even if there be a left eparterial bronchus, it has never been observed to be tracheal. The accompanying scheme and table will illustrate what has been said. (Fig. 4.)

We have now to discuss the possibility of any surgical treatment for a totally different kind of pulmonary cavity from those considered in the last lecture—if, indeed, the term pulmonary cavity can be considered in any way applicable. I mean bronchiectasis. It is in my experience a much less satisfactory condition to deal with. It does not devolve upon me to say much about the causation or pathology of bronchiectasis; a few preliminary remarks must, however, be made. Bronchiectasis consists of a dilatation of some part of the bronchial tree, and is at first nothing else, though in some cases the occurrence of ulceration no doubt causes an increase of the size of the cavity at the expense of the surrounding pulmonary tissue. "Two principal forms of bronchial dilatation," says Dr. Theodore Williams,[3] "the cylindrical and the globular, are found in the post-mortem room; in each case the tertiary bronchi are dilated, so as to measure as much as or even more in circumference than the primary. In the cylindrical form the dilatation is more general, the tubes being stretched like the fingers of a glove; the walls are thickened, the submucous and mucous layers are hypertrophied, and stand out in folds. The generally tubular form of the bronchi is owing, according to Hamilton,[4] to the traction on their ends from an adherent pleura. In the globular form the tubes are dilated at or near their ends into pouches or ampullæ of large size, the adjacent dilated tubes often communicating freely with each other, the mucous membrane appearing to form folds or wrinkles in their interior, &c." Dr. Douglas Powell[5] says: "There are two forms of bronchiectasis, the *cylindrical* and the *sacculated*. In cylindrical or fusiform bronchiectasis,

FIG. 4.

This figure shows the relation of the pulmonary artery, A, to the lateral bronchi. (Modified from Aeby.) *a*, Eparterial bronchi. *b*, Ventral hyparterial bronchi. *c*, Dorsal hyparterial bronchi.

I. Eparterial bronchus on both sides.
  1. Both bronchial—e.g., horse.
  2. Right tracheal, left bronchial—e.g., dolphin.
II. Eparterial bronchus on the right side only.
  1. Bronchial—e.g., man.
  2. Tracheal—e.g., sheep.
III. No eparterial bronchus—e.g., porcupine.

the dilatation involves some length of the tubes, varying from a few inches to a system of tubes ramifying through an entire lobe. The enlargement is uniform throughout the length of the tubes affected. In sacculated bronchiectasis a restricted portion of the tube is enlarged to a globular form, from half an inch to an inch in diameter. The whole calibre of the tube is as a rule involved, and the ectasia may be solitary, or there may be many scattered through the lung. As a rule, this form of bronchiectasis is situated at the peripheral portions of the lung corresponding with the smaller bronchi, and small openings lead from the rounded and apparently closed distal side of the sacs to fine tubes, the branchlets of the widened bronchus."

Here, then, in very similar words, are descriptions by two physicians to this hospital of the state of things for which the surgeon is asked to find a remedy; not, be it observed, as in the cases which were before described—a single cavity surrounded perhaps by much diseased lung tissue,—for here the whole of the bronchial system, or a great part of it, is to a greater or less extent involved, so that, even if one

[2] W. Braune and H. Stahel (Archiv. f. Anatomie, Feb., 1886—*vide* International Journal of the Medical Sciences, July, 1886) throw doubt on Aeby's figures, saying that his method of filling the bronchi by pouring in a fusible metal dilates the lower parts of the tubes more than the upper. They say that there is a slight contraction again at the lower part of the trachea.

cavity considerably exceed the rest in size, it is, after all, only part of a much larger and most tortuous space, and most likely communicates round the corner, as it were, with other dilatations more or less exactly resembling itself. Hence the difficulty, and hence the doubt whether surgery can ever do much for this sad condition of things. It is one, however, involving so much discomfort both to the patient and to all who come into contact with him, and so much danger to life, that we should not be justified in giving up the attempt to cure it. Our main objects, then, in attempting to open a bronchiectatic cavity are: (1) that the secretion from it may be prevented from continuing the mischief in its passage over the bronchi, or as it is drawn down into other parts of the lung; (2) that the cough may be diminished, it being held that the expiratory efforts have something to do with the production of the dilatation; and (3) because it is well known that though patients with this disorder may go on for a number of years without succumbing to it, a very considerable number become comparatively soon affected with some form or other of blood poisoning. With these objects in view, and notwithstanding the experience of the cases to be described, I should feel disposed to recommend an operation if the physician were to express a strong opinion that the cavity was a single one, or at least that the mischief was principally caused by one main cavity, and also in those cases where it has arisen, as not uncommonly happens, from the irritating presence of a foreign body in one of the bronchi. In the latter case, it would be done in the hope, though not a very sanguine one, of removing the foreign body; in the former, in the fear that, notwithstanding the diagnosis of a single cavity, there would be found others in the same lung, and not improbably in the other lung, which, it may be, was supposed to be sound.

It has been pointed out that bronchiectasis may follow the introduction of a foreign body into the air-passages, and of this condition I am able to supply two examples. The first case, however, was not one of simple bronchiectasis, and it may be observed that this is not the invariable sequence of such an accident. I reported a case which occurred to Dr. Rudyard of Watford[6], in which a piece of barley grass which a child had placed in its mouth caused for some time a troublesome spasmodic cough, but at last, being always drawn forwards by its peculiar shape, worked its way through the pulmonary tissue, through an intercostal space, and ultimately pointed by its sharp extremity beneath the skin in the back below the angle of the scapula. In this connexion I must also mention the case of a young man who inadvertently allowed a grain of bearded wheat to enter his larynx, and who afterwards developed an abscess in the neighbourhood of his hyoid bone. The abscess was taken for a strumous affection, and it was even contemplated that he should give up his studies at Oxford, or at all events consider himself a delicate individual. The free opening of the abscess and the scraping out of the cavity with a sharp spoon led to the removal of the foreign body and a complete recovery.

I believe it is always wise not to put on one side a patient's account of the inspiration of a foreign body, if anomalous chest symptoms are present; in my experience one is more likely to be in error by doing so than by accepting the account, and it is possible, though perhaps not very likely, that a careful search may lead to the removal of what is certainly a very serious cause of mischief. In the case to be recounted we paid but little attention to the history, and accordingly did not arrive at a correct diagnosis.

W. H——, aged seventeen, was admitted under Dr. Powell on May 11th, 1885. There was nothing in his family or previous history to account for pulmonary disease, except that he said that "some time previously" he had swallowed a piece of grass, which was followed by the spitting of a little blood. In January, 1885, his present illness began with pain in the right side and a hard dry cough with but little expectoration, which did not prevent his following his occupation. He was an out-patient at the Westminster Hospital for five weeks, after which he became worse, and remained at home until the time of his admission. When he came under notice he had great pain in the right side, a troublesome cough, and some expectoration tinged sometimes with blood. The temperature was 99·4°, the pulse 114, and the respiration 17. The right side was flattened and motionless; dull below the fifth interspace, an inch and a half below the nipple, in front; and dull below the scapula behind. There was no vocal fremitus or resonance over the dull area, and the breathing was weak, while above the dull area there was vesicular breathing with scattered râles. The heart's apex was in the fifth interspace, half an inch outside the nipple. The left lung appeared to be healthy. Between May 11th and June 4th things remained much in the same condition: the temperature varied from 98·6° to 100° in the morning and 100° to 103° in the evening; the expectoration, which was muco-purulent, varied from eight to fourteen and sixteen ounces, while the physical signs did not alter. On June 4th I made an incision in the sixth interspace, and passed the finger into an irregular cavity with loose friable walls, extending upwards and backwards, and containing a considerable quantity of fetid sanguineous pus. The cavity was evidently in the lung tissue, and not in the pleura. The wound was purified, and dressed with oakum. On the 9th it was noted that he had greatly improved since the operation, the temperature remaining normal and the discharge becoming less in quantity and less offensive. His appetite improved, but the expectoration, though much diminished, did not cease, and remained muco-purulent, as was afterwards accounted for by the dilated condition of the bronchi and the presence of the foreign body. Between the 9th and the 15th the temperature again became peaky, and the expectoration increased in quantity, while some redness and tenderness appeared about the wound. On the 16th Dr. Waugh, the resident medical officer, enlarged the sinus and put a needle into the swelling, extracting some sanious pus. There was no change of consequence till July 2nd, when he first complained of headache. The sputa remained the same in quantity (from fourteen to sixteen ounces), and were very offensive. The physical signs continued to be as on admission, but the temperature was normal or subnormal. It was intended to make a further investigation, as we clearly had not reached the bottom of the trouble; but the headache, which varied from day to day, proved to be the precursor of unmistakable cerebral symptoms, and on July 7th the patient died from what proved to be, as we had thought, an abscess of the brain.

It is a remarkable fact, as has been pointed out by Dr. Percy Kidd and others, that cases of pulmonary abscess seem especially liable to be followed by cerebral abscess, to account for which I do not see any obvious hypothesis; at present we can only accept the occurrence as an apparent fact, and must wait for an explanation. At the post-mortem it was found that there were scattered tough adhesions uniting the lower lobe of the right lung to the chest wall, and that in this lobe the lung tissue was collapsed, airless, and somewhat indurated. The external opening led to a space within the ribs which communicated upwards by means of a comparatively narrow sinus with a cavity in the lower lobe, but also by a track which led downwards between the diaphragm and the ribs with another cavity of small size between the upper surface of the liver and the diaphragm, probably due to burrowing of the pus before the abscess was opened. (*Vide* Dr. Magrath's case mentioned above, THE LANCET, p. 511.) All the air-passages of this side were reddened, and there was some blood in the trachea. All the bronchi in the lower lobe were dilated, and contained a thin reddish fluid; in one of them was found a part of an ear of grass, with the stalk upwards, lying loose in the cavity of the tube, which at this point showed no change except a dark reddening of the mucous membrane; a short distance below, however, there was a patch of superficial ulceration, corresponding no doubt to a previous lodgment of the foreign body. In the middle lobe was a thin-walled cavity as large as a small egg, the bronchus leading to which was only slightly dilated. The rest of the lung and the left lung were healthy. The cause of death was a large abscess in the occipital lobe of the brain, which had ruptured into the posterior cornu of the lateral ventricle. There was no disease of ear, and no sign of tubercle in the body.

What strikes one in looking at this lung is that the mischief is limited to the part below that at which the straw lay. The changes, however, are just the same as we shall find in the other cases of bronchiectasis. The lung is hard and fibrous, and the bronchi have much thickening round them, and are dilated into cavities. This must all have been due to the secretion pent up behind the piece of straw. The rest of the lung was practically healthy, and it thus seems likely that if the foreign body had been discovered and removed the patient might have made a good recovery; but

[6] Clinical Society's Transactions, vol. xv., p. 156.

Digitized by Google

this discovery of a foreign body in the lung is by no means easy, as the next case will show. The track between the cavity and the external opening had closed very much, and this tendency to close is, I think, common when sinuses pass through lung tissue. I have seen a remarkable example of it in a case of hydatid of the liver rupturing through the lung, in which, at the post-mortem examination, it was hardly possible to find the track by which the contents of the cyst had been discharged.

(To be concluded).

PYREXIA AND HYPERPYREXIA.

BY T. J. MACLAGAN, M.D., M.R.C.P.,
PHYSICIAN IN ORDINARY TO THEIR ROYAL HIGHNESSES PRINCE AND PRINCESS CHRISTIAN OF SCHLESWIG HOLSTEIN.

(Concluded from page 619.)

OF the subjective phenomena of the febrile state none is more prominent than thirst. To allay this there is consumed a much larger than usual quantity of water. So great is the demand for water that each draught has but a transient and temporary effect in allaying the thirst which is consuming the sufferer. Very soon another is called for, and another, and another; and the demand continues so long as the fever lasts. In this way the quantity of water consumed during a week of fever far exceeds the ordinary requirements of the system. While this large quantity of water is being consumed, less than the normal amount is being eliminated, and hence the phenomenon with which we are now dealing is usually referred to as excessive *retention* of water. It is obvious, however, that the enormous quantity of water consumed during a febrile attack cannot be retained as water; it is equally certain that is not eliminated, for all the while the ordinary channels of water elimination are less than usually active; the skin is dry and unperspiring, the bowels are constipated, and the urine scanty. If neither retained in the system as water nor eliminated, it must somehow be used up in it. Parkes suggested that during the metamorphosis of the albuminous tissues there may be formed a gelatinous compound intermediate between them and urea, and possessing in virtue of its gelatinous nature a great attraction for water. It is difficult to see how such an agency could produce such a result, or how any retrograde compound could attract water more powerfully than the tissues, which so urgently require it. But granting that it could, there are still insuperable obstacles in the way of our accepting this explanation. In the first place, why should such a compound be formed in such excessive quantity? In the second place, if the disintegrative changes of the nitrogenous tissues thus stop short of the formation of urea, how comes increased elimination of urea to be a characteristic of the vast majority of the cases in which this excessive retention of water occurs? No; the thirst of fever is an expression of a real want of water in the system; it is a cry for more; and the coincident occurrence of increased consumption and decreased elimination is distinct evidence that the water which is drunk is somehow used up in the system. But the normal ingredients and tissues of the body require no such large supply, and are incapable of utilising it. The only abnormal agency of which we know is the contagium, and this, we know, necessarily consumes a large quantity of water during its growth and reproduction. In this consumption of water by the contagium we have the explanation of the increased demand for water, and of some of the usual symptoms of fever. The thirst, the loss of appetite, the dry skin, and the scanty urine result from the consumption by the contagium of the water, which is requisite to enable the stomach, the skin, the kidneys, and all the other organs to perform their functions aright; and so this phenomenon, the direct and necessary result of the propagation of the contagium, becomes the immediate cause of many of the ordinary minor phenomena of an attack of fever, as well as of some of the leading and essential ones.

Though the consumption by the contagium of the nitrogen and water destined for the nutrition and repair of the tissues is the chief, it is probably not the sole, agency in producing the tissue waste characteristic of fever. A probable adjuvant cause is that "morbid general increase of tissue metabolism" which has been regarded by the advocates of the combustion theory as not only the essence of the febrile state, but as the cause of the wasting of the febrile body. Though that wasting is, as we have just seen, mainly due to other causes, this one is probably not altogether void of share in its production. What we have to do is to consider how it is brought about. The evidence of its existence is not so much increased tissue waste—for that is otherwise accounted for—as increased elimination of urea, which must result from increased tissue disintegration. To this phenomenon we must therefore for a moment direct attention.

Urea is formed in the urea-forming glands from the retrogressive store albumen. If the propagation of the contagium in the system is competent to cause an increased flow of retrogressive store albumen through these glands, it is competent to cause increased formation of urea. Of its competence to do this there can be little doubt. Tissue metabolism consists of two distinct processes—the taking up of new material and the giving off of old. Both actions take place in and around the capillaries, and are so contemporaneous that it is impossible to say either that the old nitrogen of the organ albumen is deposed by the fresh nitrogen of the constructive, or that the constructive steps in to fill up a gap created by the passage backwards into the circulation of the used-up nitrogen of the organ albumen. The two actions are simultaneous—neither actually preceding the other any more than in osmosis the passage of one liquid through a membrane precedes the passage of another which exists on the other side. While this simultaneous double action is going on, the contagium particles step in and convert into their own protoplasm so much as they require of the nitrogen of the constructive albumen. The moment at which they lay hold of it is that at which it is about to be appropriated by the tissues—the moment, that is, at which it is in the transition state which it must assume in passing from the condition of constructive to that of organ albumen. The protoplasm of the tissues and of the contagium is formed at the same time, in the same place, and from the same material; and so close is the struggle between the two for the possession of the nitrogen of the constructive store albumen that the contagium seizes upon it at the very moment at which it is about to be incorporated with the tissues, and consequently not before some of the nitrogen of the used-up organ albumen, which it was on the point of replacing, has passed back into the circulation as retrogressive store albumen. The moment at which the constructive albumen is undergoing the change which normally results in the formation of organ albumen is that at which its nitrogen is taken up by the contagium. The simultaneous action by which the organ albumen is converted into retrogressive is equally far advanced; the contagium steps in to deprive the tissues of much of what they require and *are in the act of appropriating* for the formation of organ albumen. No such agency intervenes to prevent the completion of the contemporaneous action which results in the formation of retrogressive albumen; that action, therefore, continues as usual; and thus is brought about the physiological anomaly that a diminished consumption of nitrogen by the tissues is accompanied by an increased elimination of nitrogen by the kidneys.

Another and essential phenomenon of fever intervenes to aid this result. Tissue metabolism depends, among other things, on the circulation through the tissues on a due supply of blood. The more active the circulation is, the more active also, *ceteris paribus*, will be the tissue changes. In health the heart beats at the rate of about seventy a minute, and at each beat sends onwards about the same quantity of blood, so that in twenty-four hours the heart has sent the fill of its left ventricle through the body 100,800 times. In fever there is increased rapidity of the heart's action and of the circulation through the tissues. Supposing it to beat 120 times per minute, the fill of its left ventricle would be sent through the circulation 172,800 times in twenty-four hours. As there is no diminution, but probably an increase, in the amount of retrogressive albumen in the blood, it is evident that one result of the increased rapidity of its circulation must be the conveyance in a given time to the urea-forming glands of a more than usual quantity of the material from which urea is formed, and consequent increased formation of urea.

Another and necessary result of this increased tissue metabolism is increased production of heat, the phenomenon whose causation we are supposed to be specially investigating

Digitized by Google

when considering the theory of fever. This increased body heat is, it will be seen, only one of a group of phenomena, each of which is the direct or indirect result of the propagation of the contagium in the tissues. The direct action of the contagium consists in the consumption by it of the nitrogen and water of the constructive store albumen. The results of this action are: 1. Impoverishment, and consequent wasting of the nitrogenous tissues. 2. Increased demand for water, with its attendant thirst, dry skin, scanty urine, and constipated bowels. 3. Increased tissue metabolism, with its attendant increased rapidity of the circulation, increased formation of urea, and increased production of heat. Thus we find that the phenomena which must result from the propagation of an organism in the tissues are exactly those which are found to characterise the febrile state. Thus is explained the mode of action of the poisons of the specific fevers. Thus, too, is exemplified the combustion theory of fever.

Let me again point out that the two theories of fever which we have been considering are not antagonistic. Each has its own special sphere of application. The chief and most important applications of the neurotic theory have already been indicated. It applies probably to all cases of hyperpyrexia, to all rises of temperature resulting from non-inflammatory lesions of the nervous centres, and probably, too, to most forms of ephemeral fever. By the combustion theory are to be explained the febrile symptoms of the specific fevers, malarial fevers, rheumatic fever, pneumonia, and all febrile diseases, whose poisons may reasonably be regarded as minute organisms whose morbific action is dependent on their organic development. It is probable, too, that the fever of all inflammations is also thus produced. Not that all inflammations are produced by foreign organisms (though many probably are), but because excessive activity in the minute cellular elements of the tissues will have the same result on their metabolism as the propagation in them of foreign organisms.

Cadogan-place, S.W.

ON THE ACTION AND PROPERTIES OF THE WHITE BLOOD-CELLS.

DO THE INTRA-VASCULAR WHITE BLOOD-CELLS POSSESS THE PROPERTY OF AMŒBOID CHANGE OF SHAPE AND POSITION? IS THE ASSEVERATED MIGRATION OF WHITE BLOOD-CELLS AN OBSERVABLE PHENOMENON OF INFLAMMATION?

BY WM. A. HAMAN, M.D.

IN the American reprint of THE LANCET for the month of March, 1885, Mr. Wharton Jones has an interesting paper addressed to professors of physiology and pathology, advising them not to teach that white cells migrate from the veins and capillaries during inflammation until they have verified the fact by observations of their own. In this paper Mr. Jones makes two unqualified assertions which negatively answer the questions which constitute the caption of this communication. Prior to the appearance of Mr. Jones's paper I had unreservedly accepted the doctrine of migration as beyond dispute, but after reading the convictions of one of the pioneers in the microscopical study of the circulation and inflammation, I thought I would repeat some of these experiments for my own satisfaction. I accordingly made twenty prolonged observations on the transparent membranal web, mesentery, and tongue of toads and frogs, using Schäfer's work on "Practical Histology" as a guide to the systematic display of these parts.

Concerning the first question, I would remark that, although Dr. Henry Green says "amœboid movements have never been seen in the white corpuscles whilst within the vessels,"[1] agreeing in this respect with Mr. Jones, while a firm believer in Cohnheim's views regarding migration, I am convinced that both are in error. I have demonstrated the contrary to my own satisfaction at least. During last September, I had a small vein in the mesentery of a frog under a ¼-inch objective (using a cover-glass); there were white globules hugging the vessel wall, while the axis of the contents of the vessel oscillated gently to and fro; the walls of the vessel were sharply outlined, the surrounding tissue being nearly free from stray globules, and the colourless corpuscles were well defined. I carefully and closely watched one white globule in the centre of the tube; it was motionless, but gradually changed its shape by throwing out processes, and finally by imperceptible activity reached one side of the vessel, and there changed from the circular shape to that of a somewhat irregular square. I thought I was now going to witness migration; but in a short time it left the side of the vessel, resumed its circular shape, and returned to the centre of the vessel, where it let go its hold on the vessel wall and oscillated to and fro with the current in company with the other red and white globules—thus showing it to be still within the vessel. I believe, notwithstanding the assertions of Mr. Jones and Dr. Green to the contrary, that it was a *bonâ-fide* instance of amœboid change of shape and position of a white corpuscle while still within a vessel. Using the same objective, I afterwards observed the same phenomenon in the case of other colourless cells. On account of the inconveniently short working distance of the ⅛-inch objective, the ¼-inch is generally used, which, possessing a less power of amplification, may account for the failure to witness this change of shape and position; by having the membrane perfectly horizontal, and using very short pins to confine the membrane to the frog-plate, I experienced no great difficulty; a ¼-inch glass used in conjunction with an achromatic amplifier would give the same amplification as a ⅛-inch objective without the inconvenience of a short working distance.

In reference to the second question, I would say that if I was at all prejudiced it was in favour of the migration theory; for, if correct, it very much simplifies the pathology of inflammation. I used the web but once, as on account of its comparative thickness and the numerous pigment cells contained in it its examination was not so satisfactory as the clear transparent mesentery. In some instances I relied on atmospheric air to light up the inflammatory process; while in others I applied acetic acid, crystals of silver nitrate and copper sulphate, and an iron heated short of red heat and in boiling water. With the exception of the web, I invariably noticed, at the first glance at the exposed membranes, that there were free cells on their surfaces. These are the white cells not only coming, as Mr. Jones observes, from the peritoneal secretion, but also from the vessels, as red cells are also to be found. Many of these cells, without doubt, come from the vessels divided in opening the abdomen, and from the pricks of the pins made in confining the mesentery; small vessels must also be severed in properly displaying the tongue. No matter how much care is taken in the preparation of these membranes, free cells will always be found on their surfaces, and no doubt are mistaken by some to be migrated globules; but a very little care in observing them will readily dispel such an illusion. Furthermore, I always noticed that the great majority of them can be removed by means of a camel-hair brush; those which do not come away are no doubt on the under surface of the membrane, where manipulation with the brush is difficult and awkward, or else, being bodies of microscopic size, escape being entangled in the hair of the brush. My plan was to select a few small veins with a clear unobstructed piece of membrane on each side of the vessels, and then watch until the current became slow and finally stagnant, with complete coagulation of their contents. I never saw, no matter how long the vessels were under observation, any white cells appear in the surrounding clear tissue which could not be accounted for on another more plausible theory than that of migration. Vessels were occasionally seen the tissues bordering which were not free from leucocytes, and which could not be brushed away. I do not believe they were migrated globules, for they did not change their position, and if the membrane was occasionally brushed they did not increase in number. I believe they were free peritoneal and vascular cells fixed to the membrane by their viscidity and desiccation prior to inflammatory effusion. I several times saw a small vein, sharply defined and with clear tissue surrounding it, in which a colourless cell was to be seen that presented the appearance as though a small portion of it were partly through the vessel wall; but after long waiting, during which time it presented no change of any kind, it was suddenly whisked along with the blood-current. I repeatedly proved, to my own satisfaction, by *transitional* focusing, that many of the cells that occupied positions which rendered them liable to be mistaken for migrating leucocytes were on a plane different from that occupied by the vessel. The most deceptive

[1] Green's Pathology and Morbid Anatomy, sixth edition, p. 246.

Digitized by Google

simulation of migration I witnessed was observed while watching two leucocytes which looked for all the world like globules that had partly escaped from the vessel. As they were the only ones, and the surrounding tissue was quite clear and free from other globules, I was less liable to make a mistake than would otherwise have been the case. They appeared to be attached to the wall of the vessel by a narrow pedicle, which gave them a pear-shape. In about an hour they were quite free from the vessel, and had moved a short distance away from it; but in a comparatively short time they returned to the vessel wall again, and appeared to almost bury themselves in it, when they reappeared, still apparently attached to the vessel wall. This peculiar behaviour made me doubt their being emigrant globules, but I was finally convinced, by their suddenly rapidly oscillating, in no fixed direction, to and fro in overlying serum on the peritoneal (the vessel was in the mesentery) surface, so occasioned by the beating of a neighbouring large artery. This proved their presence on the surface of the mesentery, wandering over its surface, and thus occasioning the similarity in appearance to migration. This required an hour and a half of continuous observation; so a hasty conclusion in favour of migration would no doubt have been arrived at by many.

On reading descriptions of the migratory process by different writers one is struck with two facts: (1) That exceedingly few quote their own observations in favour of migration, but quote either Cohnheim's or those of Burdon Sanderson; (2) the great discrepancy in the ease with which they (different writers) say migration can be observed. Burdon Sanderson avers, "From the description given above it might be inferred that the experiment is one of great simplicity, whereas in actual practice it is attended with very considerable difficulty; so much so, indeed, that most persons who have tried it have found failure more frequent than success. The principal sources of difficulty are: (1) That the time occupied in the first stage of the process, during which the circulation is going on with unabated velocity, is extremely variable; (2) that if from weariness or inadvertence the attention of the observer is diverted from the selected vein at the commencement of the process of migration, he is very unlikely to succeed in seeing what he desires to see afterwards; for inasmuch as leucocytes are escaping simultaneously in various parts of the mesentery, they soon accumulate in such numbers that their mode of exit can no longer be distinguished. Yet, notwithstanding these difficulties, no one who has time and patience enough need fail; great care in manipulation is required, but no extraordinary dexterity."[2] (A camel-hair brush, as before stated, occasionally applied to the surface of the membrane will prevent and will remove the obstruction to the clearness of view occasioned by these "accumulated migrated" corpuscles which gradually ooze from the cut vessels). I now turn to Schäfer, who, speaking of the exposed lymphatic surface of the tongue, says: "Moreover, the mere exposure of the lymphatic surface soon causes inflammatory changes, and after the preparation has been made a few minutes only, the first commencement of these is seen in the sticking of the pale corpuscles to the walls of the vessels, speedily followed by their migration from the veins into the surrounding tissue. Nowhere can the fact be more clearly established, and the details of the process more accurately followed than here."[3] If migration is an observable fact, one of these gentlemen is in error, and I am sure it is Mr. Schäfer, who, I have not the least doubt, mistakes the free leucocytes on the surface for migrated corpuscles in the parenchyma of the tissues. My observations have been too few to warrant me in coming to a definite conclusion; yet the result of my efforts to arrive at the truth in conjunction with the differences in the statements of actual observers who accept the doctrine of migration give some support to the assertion of Mr. Wharton Jones. I intend pursuing the subject still further, and if after as many careful observations I do not witness migration, I think I shall be justified in doubting, if not migration, at least observable migration.

THE epidemic of measles has rapidly spread in Warrington during the past two or three weeks, and the day-schools in the town have been closed with a view to prevent the spread of infection.

HYSTERECTOMY FOR FIBRO-MYOMA UTERI IN A PATIENT FIFTY-SIX YEARS OF AGE.

BY J. KNOWSLEY THORNTON, M.B., C.M.,
SURGEON TO THE SAMARITAN FREE HOSPITAL.

THE following case seems to me sufficiently rare to merit separate publication.

On Nov. 3rd, 1886, I saw in consultation with Dr. Braxton Hicks and Mr. Rand of Dulwich a single lady, aged fifty-six, with a very large, solid abdominal tumour. After examination, I agreed with the previous diagnosis—namely, that it was uterine. The cervix was obliterated, and the os could only just be reached as a small opening at the top of an elongated funnel-shaped vagina. Menstruation had been regular and scanty up to 1880, and then became rather more profuse. In July, 1881, the patient discovered a small lump in her right side, and about the same time menstruation became irregular, and she had some severe floodings. This state of things continued more or less till the early part of 1885, the tumour meantime slowly increasing in size. She then stopped menstruating for a whole year, had one period, and did not menstruate again for another six months—i.e., till I first saw her. During this last six months increase in size had been much more rapid and decline of general health so marked that Dr. Hicks advised that I should be consulted as to the possibility of operation. I came to the conclusion that hysterectomy was possible and justifiable, but thought it right to tell both the patient and her friends that the great size of the tumour, together with its very broad base, made the operation unusually formidable and dangerous. I have twice performed hysterectomy upon single women at the age of fifty-five, in the one case removing an enormous fibro-myoma, which had become cystic with rapid increase of size, and in the other a small fibro-myoma for excessive hæmorrhage, which rather increased than diminished after the usual period for the menopause; and in another case I operated on a woman of fifty-eight, in consequence of profuse suppuration in the tumour, the pus escaping through the uterus in such quantity as to seriously undermine her health. These three patients are now all in the enjoyment of good health.

The special interest in the present case does not therefore lie in the age of the patient, but in the fact that the tumour appeared first about the usual time of change of life, and grew steadily during this period, and after it was practically complete increased so rapidly in size as to threaten the patient's life. Her family history is a remarkable one. She was the eighth of a family of sixteen. Her mother died of some uterine disease at sixty-four, one sister died in infancy, one of phthisis at nineteen, another of epilepsy, and another of scarlet fever. The eldest sister had a tumour removed from her groin ten years ago, another sister had a mammary tumour removed four years ago, and the youngest sister has been twice operated upon for thyroid tumour; all three are living.

On Nov. 8th, 1886, Mr. Stormont Murray administering chloroform, Mr. Malcolm assisting, and Dr. Braxton Hicks and Mr. Rand being present, I removed the tumour with the uterus down to the internal os and both ovaries and tubes. The latter were ligatured off, and the wire of Koeberlé's serre-nœud was passed through the broad ligament on each side just below the cut angle made by removing the appendages. It was necessary not only to secure the broad ligaments on each side as in ovariotomy, but also to secure separately on each side a large mass of vessels lying deeper on the surface of the tumour, and also to enucleate the lower part from the pelvis, peeling back the bladder, and enucleating the mass from the whole floor of the pelvis from the rectum and sigmoid flexure and left ureter on one side, and from the cæcum and right ureter on the other, and well above the sacral promontory posteriorly, so that the raw surface, apart from the ovarian pedicles and uterine base secured in the serre-nœud, was larger than that made in amputating at the hip-joint. Many large vessels were secured over this surface, and its edges were laced over with fine silk. Some venous oozing deep in the pelvis I failed altogether to stop, and I therefore placed a glass tube above the pedicle and at the bottom of the large cavity left by enucleation. The whole operation was performed antiseptically, the stump dressed with solid perchloride of iron, and the tube covered

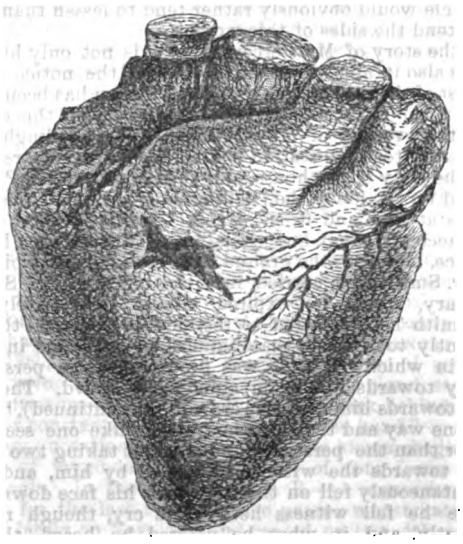
Digitized by Google

with the sponge dressing. For some days after the operation a considerable quantity of dark blood was discharged from the tube every twelve hours, sometimes several ounces; and the glass tube was not finally removed for more than a month, and was then replaced by a red rubber tube, which was gradually shortened and finally removed in eight weeks, when the patient got up. The convalescence was very steady considering the formidable nature of the operation, the only troubles being the persistent oozing of blood, which was apt to occur and increase on any extra movement, and a sharp rise of temperature and pulse on the evening of the fifth and morning of the sixth day, requiring the use of ice to control it. From the time the ice was removed from the head almost to the time the patient left my care there was marked polyuria, the secretion more than once being over seventy-two ounces in the twenty-four hours. I have before noticed the same thing in cases after a rather prolonged use of ice to the head, but it does not seem to do the patient any harm, and, so far as I have been able to discover, is not associated with albuminuria or any other change in the urine. The tumour, after much blood had drained from it, was weighed at 25½ lb., but I have no doubt was really much heavier. I found the people only had weights up to 25½ lb. The great size of the pedicle made the serre-nœud long in separating, and I did not finally remove it till the twenty-fourth day. I usually remove it, if it does not separate spontaneously, about the fourteenth day.

I was assisted in the after-care of the case by Dr. Hicks, Mr. Rand, and Mr. Malcolm, and the patient was most excellently nursed by one of the nurses from the St. Helena Home. She was herself bright and cheerful throughout, in spite of the slow convalescence, and the change in her appearance was so marked that friends who visited her said that she appeared at least ten years younger. The only point in the operation to which I would call attention is the separation and ligature of a second layer of large vessels after securing the broad ligaments for the removal of the ovaries. I find that in these very large tumours this second layer can always be recognised and lifted from the sides of the uterus, and after they are secured, as well as the ovarian vessels, very extensive enucleation may be rapidly performed without fear of dangerous hæmorrhage, in cases in which, upon first opening the abdomen, it seems quite impossible that the mass can be removed with any reasonable prospect of preserving the life of the patient.

Portman-street, W.

SURVIVANCE AFTER GUNSHOT WOUNDS OR OTHER INJURIES OF THE HEART.



BY BRIGADE-SURGEON W. CURRAN,
ARMY MEDICAL DEPARTMENT (RETIRED).

HAVING discussed this question from the standpoint of the lower animals in another journal, and having accummulated some materials about it in its relations to our own species, I am anxious to summarise these in this place, and so complete the record of the matter so far as I am acquainted with it. I am, of course, aware that the subject has been exhaustively dealt with by other and abler hands than mine; nor do I pretend to be able to shed any new light on so well-worn a topic. All I undertake to do is to introduce a few of the more classic or historical illustrations of this kind that I have met with in the course of my reading, or that have escaped the notice of the ordinary collectors, and then relate a case that came under my own cognisance at Peshawur, which, if not unique of its kind or *per se*, is, I should fancy, nearly so. Anyhow, I never saw or heard of anything like it, and the uncertainty or complexity of the symptoms by which this lesion is characterised during life must be my excuse as well as my justification for ignoring, or at least for not dwelling on them at all in this place.

The materials here referred to would, I think, justify me in extending the scope of this paper, and this too was at one time my own intention. But, alas for the vanity of human wishes! just as I had sketched out a programme of this kind for my own guidance, I bethought me of its medico-legal bearings, and on looking into the great works of Chevers and Taylor—to go no farther afield—lo and behold! there was the whole question thoroughly threshed out. To add to my perplexity or humiliation, I further found that, *quoad* its surgical bearings, one Fischer, a German, had been before me, and so it became clear to me that, if I would not poach on their preserves or carry coals to Newcastle, I had better be content with what I had gleaned in this bared field myself, and shine as a compiler, if I could not sing or shine in any higher key. This, then, is my standpoint—as it will, I trust, be my shield and defence against the too-exacting requirements of a carping criticism; and the interest or the superstition with which wounds of this kind have ever been regarded will, I am assured, relieve, in some measure at least, the barrenness and monotony of the tale I have to tell about them.

That all these cases exhibit a larger measure of tolerance on the part of this central organ than is popularly assigned to it is undeniable, and equally certain is it that such a tolerance has been specially provided for by nature. So complex, indeed, is the distribution of its muscular fibres that their minute arrangement may be almost said to be still *sub judice*; and as to the mechanism of the fact or force whereby it ministers to the wants of our economy, that is yet quite as much a *crux* as was at one time the circulation itself, or as is still the use of the appendix vermiformis cæci. We know, on the other hand, that it has frequently undergone rupture even in a healthy subject, as the result of a squeeze or of a blow that has left no trace behind it. It has also been displaced without undergoing any rupture by such external violence as has seriously compressed its cavities or broken

FIG. 1.

several of the ribs by which it was surrounded; and as to other minor instances of its endurance, freakishness, or "deviation from the perpendicular," they are so numerous as not to need any more detailed reference or indication here.

Thus—to mention only a few of the more striking ones—one (de Torres) is quoted by Chelius as describing a case in which the base of this structure was as low as the umbilicus; another (Ramel) mentions the case of a girl of ten, in whom the heart was placed below the diaphragm; and, stranger still, Deschamps is said to have found it, in one instance at least, in the region of the left kidney. I have myself quoted, but without attaching much importance to such narratives, several other curiosities of this kind in a paper headed "On Malposition or Displacement of the Heart" which I contributed in 1861 to the "Indian Annals of Medical Science," and having thus cleared the way for the histories promised above, I will now proceed to the statement of them.

The interest associated with the accompanying illustration (Fig. 1), for the block of which I am indebted to the courtesy of Mr. F. Le Gros Clark, is enhanced by the fact that the heart it portrays was taken from a soldier who fought at Corunna in 1809, and who was struck by the bullet to the left of the sternum between the second and third ribs. He thought he might have been insensible for half an hour; his loss of blood was not copious. He was carried on board a fighting ship, which was crowded with wounded soldiers,

Digitized by Google

and received no surgical attention beyond the application of a piece of plaster during the voyage. The external wound was suppurating healthily on his arrival, and a probe that was introduced penetrated for nearly its whole length without meeting with any resistance. His countenance was pale; respiration frequent and laboured; pulse 120; the temperature was nearly natural. He was also very restless, and he could get no sleep, while he craved for opium. He complained occasionally of an obtuse pain in the chest, which he could not, however, define or isolate, and he was, besides much troubled with diarrhœa. His restlessness and depression increased, and, expiring on the third day after landing, and fourteen days after the receipt of the wound, this organ exhibited on section the appearance indicated in the sketch. On further examination the left pleura was found to contain two quarts of a sero-sanguineous fluid, and the lung itself, which was shrunk to a small solid mass, adhered to the spine. The thickened and distended pericardium contained half a pint of the same sort of fluid, and the surface of the heart itself was covered with a thin layer of adhering lymph. The right ventricle presented a transverse opening, about an inch in length, which penetrated its anterior surface near the origin of the pulmonary artery. On removing the heart by cutting through its large vessels, the ball was found lying loose in the pericardium, into which it had fallen during this operation, and by tracing its course within this structure, it became evident that it must have remained in the right auricle all along. The tricuspid valve had a circular lacerated opening in it, which admitted of some regurgitation, and the contraction of the walls of the ventricle would obviously rather tend to lessen than expose or distend the sides of this wound.

As the story of Mr. Perceval's case is not only historical, but as also it appears to have escaped the notice of some at least of those collectors to whom allusion has been already made, I subjoin a note of it here. It runs to this effect:—"On the evening of May 11th, 1812, he [Bellingham, the murderer] took his station behind the folding doors leading into the body of the house, and at 5 o'clock, as Mr. P—— advanced up the lobby, he [Bellingham] presented one of his pistols at him and fired. Mr. P—— reeled a short distance (the account says), and, exclaiming 'Murder' in a low tone of voice, he fell to the ground. He was instantly picked up by Mr. Smith and carried into the office of the Speaker's secretary, where he expired almost immediately." The Mr. Smith here referred to testified at the trial that subsequently took place that "almost in the same instant as that in which the shot was fired he saw a person rush hastily towards him from among the crowd. The person came towards him from the crowd" (he continued), "looking first one way and then another, rather like one seeking for shelter than the person wounded. But taking two or three steps towards the witness, he reeled by him, and almost instantaneously fell on the floor with his face downwards." Before he fell witness heard him cry, though not very distinctly, and in what he uttered he heard the word 'Murder,' or something very like it. When taken into the Speaker's office his face was perfectly pale. The blood was oozing in small quantities from each corner of his mouth, and probably in two or three minutes from the firing of the pistol all signs of life had ceased."

There was at one time, as there is still, I believe, in some quarters, an impression or belief that persons who are wounded after the manner here described invariably spring or jump into the air ere they die, and an officer who was present, in 1848, at the taking of Frankfort-on-the-Maine by the Austrians and Prussians, assured me that he witnessed and verified on the spot at least one case of this kind on that occasion. I have inquired more thoroughly into this matter, and find that, though such occurrences do sometimes take place, they are very far from frequent, and that when they do take place this spring or jump is not exclusively confined to wounds of this organ. The curious reader will find some account of this matter in a paper I contributed on the point to the *Indian Medical Gazette* of May 1st, 1876.

As regards the deaths that have been produced by stabs from knives or sword-thrusts through this organ, &c., a few historical illustrations must suffice for this occasion; and nothing need be here said about the fatalities that result from the fish-bones or other articles of that kind that reach it through the œsophagus. They are so rare as to be almost unregardable in this connexion, and so we may safely say of them *de minimis non curat chirurgia*. Not so, however, with the other stabs or thrusts of this kind that history commemorates, and we know as matters of fact that the assassination in this wise of the Duke of Guise at the siege of Orleans in 1563, as well as of Henry IV.[1] some half a century later, affected the very existence of the religious organisations or of the political factions with which they were respectively connected. But these phases of the question are also somewhat beyond the purview of our inquiry, and we find that the behaviour of this organ—which is the point that chiefly concerns us here—is in either case regulated by the amount of injury it sustains itself at the time, or by the amount of hæmorrhage and shock that are then or subsequently induced. This being so, we need not go into the details of the situation; and now for a few illustrations in point.

Describing the murder of the Duke of Buckingham by Felton, Mr. Hepworth Dixon says that "the Duke was following close, when in a narrow passage darker than the hall he stopped and reeled. Lord Cleveland, who was near him, heard a thud, and then a voice cry 'God have mercy on thy soul.' The Duke bent backward, uttered a faint scream of 'Villain,' tore from his breast a knife, and, staggering, swooned and fell. Red blood was oozing from his mouth, his eyes were filming over, and.....the Duke was dead." The other accounts of this occurrence I have read are either so exaggerated or so conflicting as to lead, nay almost oblige, me to sympathise with Walpole when he sneered at all history as a lie, or with Plunket when he compared it—though this is denied—to an old almanack. However that may be, and imperfect though these accounts are, they yet serve to show that life may survive even the most determined thrust, and the following case is still more strikingly illustrative of this point.

Dwelling on this, Mr. Sutherland Edwards says that, "after 'Le Carnaval de Venise,' &c., had been performed, the Duchess de Berri rose to leave the theatre. Her husband accompanied her to the carriage, and was taking leave of her to return to the theatre, when a man placed his left arm on the Duke's left side, pulled him violently towards him, and as he held him in his grasp thrust a dagger through his body. The dagger entered the Duke's right side, and the pressure of the assassin's arm and the force with which the blow was given were so great that the weapon went through the lungs and pierced the heart, a blade of six inches inflicting a wound nine inches long. ..... After begging that his murderer might be forgiven, and entreating the Duchess not to give way to despair, the Duke breathed his last at half-past 6 in the morning"; and the Royalist writer, Dr. Veron, who describes the attack and its consequences in greater detail, says that the wound was inflicted about 11 P.M. on the night of the 13th of February, 1820. "Il était onze heures moins quelques minutes" are his words, and "le prince allait se réveiller parmi les anges au moment où, parmi les hommes, il avait accoutumé de sortir des sommeils." In other words, he survived this terrible stroke some six hours, during which his nausea or vomiting was so continuous that the Archbishop of Paris was obliged to refuse him the sacrament, and "lorsque l'on fit l'ouverture du corps, on reconnut que le cœur même avait été blessé. Le prince aurait dû mourir sous le coup," is the opinion of our author, and, looking to the hæmorrhage that such a wound must have caused, his so-long survival is at least suggestive.

(To be concluded.)

[1] History repeats itself in this as in other matters, medical and otherwise. Thus, describing the death of the King of Demaa at the hands of one of his pages, the old Portuguese traveller, Mendez Pinto, says (Voyages and Travels, &c., Lond., 1663, p. 264) that "he [the page] stabbed the king with a little knife into the midst of the left pap, and so, because the blow was mortal, the king cried, 'I am dead.' The page," instead of being reserved for torture, as his successors Ravaillac and Gerard the slayer of William the Silent were, "was then impaled alive, with a good big stake, which was thrust in at his fundament, and came out at the nape of his neck." Short and sweet!

BRITISH OPHTHALMIC HOSPITAL AT JERUSALEM.—At a numerously attended meeting on the 30th ult. in support of this institution, it was stated that during last year 121 in-patients and 3238 out-patients had been treated at the hospital, and the number of consultations at the dispensary had been 13,462. The four beds at disposal are quite inadequate, and some of the patients have had to be placed on the floor. Resolutions recommending the hospital for increased support from the charitable public were unanimously agreed to.

CASES OF HÆMORRHAGIC TENDENCY IN MYXŒDEMA.

BY OSCAR B. SHELSWELL, M.R.C.S., L.R.C.P.

Is there any special tendency to hæmorrhage in myxœdema?

On November 15th, A. M——, aged fifty-three, suffering from extremely well marked myxœdema, wished to have a very loose upper molar tooth, which was troubling her, removed. The gum around was very spongy-looking. The extraction was attended with more trouble than at first seemed possible, the cause being the firm adherence of a portion of gum to the tooth, and which was still adherent on extraction. Rather more than the usual amount of hæmorrhage followed, which, however, stopped easily. Eight hours afterwards it recurred to an alarming extent, and was only arrested after firm pressure with dry lint for about a quarter of an hour continuously. The blood (mixed with some saliva) lost amounted probably to about fourteen ounces. The hæmorrhage recurred to a slight extent during the night of the 22nd. She had never had a tooth extracted before. There was no history of hæmophilia in herself or her family. She had never had epistaxis, hæmorrhoids, or menorrhagia.

M. A. R——, aged forty-two, also the subject of myxœdema, complained of a very loose lower molar tooth, which was surrounded by spongy gum, as in the former case. The lower incisors, also loose, were surrounded by spongy gum, which was inclined to bleed a little. The extraction of the molar on Nov. 24th was impeded, as in the former case, by the adherence of gum to the tooth. The portion adherent was very firm, and resembled strong aponeurosis rather than gum, a considerable amount of force failing to remove it. Immediately after the extraction severe hæmorrhage came on, and although pressure with dry lint caused it to stop for a time, it continued, more or less, for two hours. Eventually firm and almost continuous pressure for more than half an hour was successful. It recurred on the evening of Nov. 28th, after straining at defecation, to the extent of about three ounces. There was no hæmorrhage after this till 8.30 next morning, when, after straining at defecation, it came on, and continued on and off all day, with intervals of freedom for an hour or so occasionally. It was only arrested after much patient pressure; about twelve ounces were probably lost. On Nov. 30th, about 5 P.M., it again came on whilst lying quietly in bed. It was again stopped with dry lint and pressure. She lost about two ounces in an hour. This patient was, previously to the extraction, carefully questioned as to hæmophilia existing either personally or in her family, but she was positive that no symptom of that disease had occurred. She had a tooth extracted twenty years ago, but no unusual hæmorrhage followed. A sphygmographic tracing recently taken shows increase of tension, such not existing in a tracing taken nearly three years ago. No satisfactory tracing could be taken in the first case on account of the swelling.

Here, then, are two cases of severe hæmorrhage in this disease from so slight an injury as tooth-drawing. I have not heard of any similar case, but this may possibly be due to the fact that there seems a tendency to a loosening and subsequent falling out of the teeth, so that extraction would not often be required. Dr. James Anderson brought a case before the Clinical Society in 1884—a woman aged forty with myxœdema, who ascribed her illness to the extraction of two teeth seventeen years previously, "the bleeding from which lasted twenty-four hours, and was very copious." This case, however, would not be an instance of the subject now under consideration unless possibly myxœdema at the time of extraction had advanced sufficiently to produce certain changes, but had not developed symptoms perceptible to the patient.

Was the excessive hæmorrhage in the first two cases simply due to the spongy gums produced by a low form of inflammation caused by loose and bad teeth, or was it due to myxœdema? Have we any evidence of hæmorrhages in this disease? I will refer to several cases reported in the Clinical Society's Transactions bearing on this point. In 1881 Dr. Ralfe writes of a woman aged thirty-seven: "The patient states that her skin readily becomes bruised, and that wounds heal exceedingly slowly and are accompanied with much swelling." Dr. Felix Semon writes of a woman aged fifty-three: "The gums are often inflamed and bleed, and the swelling extends to the neighbouring parts, notably those situated underneath the chin; nails generally, and hands often, purple-coloured." Dr. Lloyd, writing of a post-mortem examination of a woman aged sixty-five, who had myxœdema, cardiac disease, and ascites, states: "There were purpuric patches on the dorsum of the forearms; the peritoneal cavity contained 240 ounces of clear brownish-yellow fluid, and there were ecchymoses everywhere." In 1882 Mr. Lunn writes of a woman aged forty-five that the "catamenia stopped in the summer of 1880," but lately "she had a severe attack of hæmorrhage from the uterus, which confined her to her bed. No apparent disease—i.e., climacteric." Dr. Cavafy writes of a woman aged fifty-nine: "Skin of backs of hands of dull purplish-red tint, which extended for some distance up the forearms." Dr. Mahomed says a woman aged thirty, who had had seven children, "had lost much blood during labour on each occasion." In 1884 Dr. Dawtrey Drewitt writes of a woman aged forty-five: "The patient was seized with severe menorrhagia whilst taking two drachms of tincture of jaborandi, losing large quantities of blood." In 1885 Dr. James Anderson's case is reported. He states: "She believes that when she pricks or cuts herself she loses more blood than others. Her gums are extremely vascular and hypertrophied; they bleed freely, and she sometimes awakes in the morning with her mouth full of blood." Menstruation commenced at fourteen, and was always copious, leaving her very exhausted. "She has never suffered from epistaxis or hæmorrhoids, has had no swellings of her joints, or dark-coloured urine." This year she was under treatment for severe menorrhagia. In the discussion on this case at the Clinical Society, Sir Andrew Clark said "that in not one of the cases which he had seen was menorrhagia absent." In one of Mr. Hopkins' cases, too, profuse menstruation had existed. In 1886 Dr. Savill writes of a woman aged forty-six: "Gums spongy, and bleed readily; has had two or three 'bilious attacks,' to which she is liable; the vomit on these occasions has contained blood from the gums." In reports from other sources we find the following:—In a case reported in THE LANCET of 1881, Dr. Lediard states: "Extensive area of ecchymosis near pin prick in vein." And again: "It was noted that a pin scratch on her chin had produced some subcutaneous ecchymosis in its track of unusual character." A girl aged twenty reported by Dr. Whipham at the Medical Society in 1885 "had had profuse menorrhagia." In THE LANCET of July 10th, 1886, Dr. Gordon, in describing a case of myxœdema following upon removal of the thyroid gland, says: "The least pressure on the skin left a vivid mark behind, so that she was constantly ecchymosed about the hand."

From these quotations it appears that the hæmorrhage in these cases of myxœdema assumed one of four forms:—1. Menorrhagia. In the case of M. A. R—— menorrhagia has existed for the last two or three years; menstruation commenced lately on Nov. 29th and ceased on Dec. 4th, and was as excessive as usual, notwithstanding the previous hæmorrhage from the gum. The menopause simply might, perhaps, account for some of these cases, but not for all. 2. Ecchymoses, caused easily. M. A. R—— says she bruises very easily, and, in fact, a bruise now exists caused by the pressure of the thumb against the jaw whilst the forefinger was pressing lint on the gum. 3. Bleeding from the gums. M. A. R—— is an example of this also. 4. Purpuric patches on the skin. A. M—— had this symptom at one time very pronounced, her arms and hands and legs, but especially her arms and hands, having very large purple patches present, which have now cleared off to a great extent.

It would appear as if there are conditions in this disease suitable for the production of excessive hæmorrhage. For instance, Dr. Ord writes in Quain's Dictionary of Medicine, referring to the amplification of connective tissue combined with mucous infiltration: "It is most developed of all perhaps in the outer coats of arteries." In his report before the Clinical Society of a post-mortem examination of a case, he says there existed "a massive thickening of the coats, particularly of the adventitia, a great increase of nuclei, and a diminution of the calibre, often approaching obliteration." This condition would necessarily interfere with the muscular contraction of the arteries, to which contraction, physiology teaches us, we owe our freedom "from danger, through even very slight wounds." I might mention that about six ounces of blood &c. from the gum of the second patient was kept for some time, but only a very imperfect clot formed on the surface; this, however, probably goes for

Digitized by Google

little when one considers the quantity of saliva necessarily mixed with the blood in this case, and which, if excessive, would doubtless prevent coagulation occurring to a great extent. Then, again, the sympathetic, through the vaso-motor system being at fault (as is perhaps shown in the patches of redness usually seen on the cheeks), might perhaps be held responsible to a certain extent for the hæmorrhagic tendency, if such exist, in myxœdema.

It is interesting to observe that a tendency to hæmorrhage has been noticed in that disease where, as in myxœdema, there is an abnormality of the thyroid gland—I refer to goitre. Dr. Bruce Low, writing from a goitre district to the *British Medical Journal*, of 1878, states that he took notes of 183 cases of goitre. Of these there were 90 women who had borne children, and out of these 31 were habitual flooders; and besides these a considerable number of others showed a hæmorrhagic tendency, especially at their menstrual periods.

I have not read of any surgical operation of any magnitude being performed on a patient with myxœdema; should such be necessary the result would be highly interesting. However, I think we have sufficient facts to lend interest to the two cases recorded above, and to lead us to be on the alert for hæmorrhage in any surgical operation, no matter how slight, in this disease; but much more evidence is required to raise what may be little more than a coincidence into a symptom.

Holborn Union Infirmary, Archway-road, N.

ACUTE EPIGASTRIC PAIN IN PUERPERAL ALBUMINURIA.

BY JOHN PHILLIPS, B.A., M.B. (CANTAB.), M.R.C.P.,
PHYSICIAN TO THE BRITISH LYING-IN HOSPITAL.

THE object of this brief notice is to draw attention to an important but apparently neglected premonitory symptom, sometimes occurring in cases of albuminuria in pregnancy. Cephalalgia and derangements of vision are usually given in every text-book as precursors of puerperal eclampsia; in a few cases, however, either in addition to, or without these two, we find albuminuric pregnant women suddenly attacked with acute epigastric pain. A case of this kind has recently been under my care. The patient, aged thirty-eight years, with six children, was in the seventh month of her seventh pregnancy. For three weeks she had had swelling of the hands and feet, with puffiness of the lower eyelids. There was occasional supra-orbital headache, but at no time was there difficulty of vision. When I first saw her I found œdema of the lower extremities extending to half-way up the thighs, the hands were swollen, the face puffy, and the skin harsh and dry. There was no pulmonary œdema, and the heart-sounds were quite normal. The urine was acid, of sp. gr. 1028, and contained one-tenth albumen with a few hyaline casts. Under treatment she improved very much, but at the end of fourteen days the œdema began to return, and she was seized with acute pain in the epigastrium passing through to the back. It was paroxysmal in character, the intervals of relief varying from ten minutes to an hour in duration. Subcutaneous injections of morphia were given, and with some success. The pain continued for two days, and, as it seemed rather to increase than otherwise, I induced labour with a catheter in the usual manner. A perfectly easy labour followed, and without any convulsive phenomena. She assured me that the labour pains were nothing in comparison to those in the epigastrium. A few hours after the termination of the labour the acute pain gradually ceased, and ten days later all albumen had disappeared from the urine.

The literature on the subject appears to be very scanty. Among our modern text-books Leishmann[1] is the only writer who describes it. He quotes Chaussier to the effect that the epigastric pain is of much less frequent occurrence than cephalalgia and visual derangements. "The suffering is described as being extremely severe, lasting often for hours; and when it is of unusual severity it is said to be an almost certain precursor of a convulsive attack." Quite recently Gross[2] described a typical case of this kind. In his patient there was slight œdema of the feet, but no headache or dimness of vision; she suffered intensely from epigastric pain for five hours, morphia giving her some relief. Without any warning she was seized with a convulsion, and died comatose in an hour's time; the child was delivered by artificial means, labour not having manifested itself. In the discussion[3] which followed the reading of this case, Dr. Doe gave the particulars of a case which had occurred in his practice. The patient was delivered of twins, and before, during, and immediately after the labour there were no symptoms of renal trouble. Eleven hours later she began to complain of severe epigastric pain, which steadily increased, and in four hours a series of convulsions seized her, and she died comatose in a few hours. Dr. Abbot related the case of a lady in whom these acute symptoms had appeared in two successive labours. In the first, after five days of intense agony, and in consequence of increasing dyspnœa, premature labour was induced; an easy labour followed, and there were no convulsions. The gastralgia disappeared as the labour progressed, and the urine became normal shortly after the birth of the child. In the second labour, three years and a half later, the pain was worse than before. Confinement took place spontaneously at the seventh month. Recovery here was much slower, the gastralgia requiring treatment for fourteen days afterwards. In addition, she was nearly blind, sight only being restored after some weeks. She ultimately made a good recovery. The above cases, five only in number, are all I have been able to meet with; and although few conclusions can be drawn from them, they indicate the reality of such a symptom occasionally existing and the necessity for prompt treatment. The pain passes from the epigastrium to the back of the lower chest; it may be variable in degree, but is usually agonising in character. Pressure and vomiting appear to relieve it somewhat. It is paroxysmal, and, although usually occurring ante partum, may, as in one case detailed, arise afterwards. Convulsions may or may not follow its advent. The pain appears to arise from some perversion of nutrition of the solar plexus; probably the circulation of vitiated blood in its substance may be the primary factor. Another point in favour of its nervous origin is that three out of the five patients suffered severely from neuralgia in other parts of the body.

WESTMINSTER HOSPITAL.

A CASE OF ADDISON'S DISEASE; NECROPSY; REMARKS.

(Under the care of Dr. STURGES.)

THE account of the following case of Addison's disease will be read with interest, especially in conjunction with the remarks which are appended to it. The notes of the case are by Dr. Courteen, senior house-physician.

Thomas B——, aged sixteen, employed travelling about the country, hawking, was admitted into the King William Ward on December 14th, 1886. The previous history of the patient, as gathered from the mother, is as follows:—His skin has always been dark, but during the last six months or so has become much darker. He has had a good deal of exposure, frequently sleeping out in the "open" at night, and often getting wet through. When four years old he was knocked down by a cart and his left arm injured; some dead bone came away from the arm, and the wound did not heal up for four years. From the time of childhood till the commencement of his present illness the patient has enjoyed good health. About nine months ago he first began to feel ill and to lose flesh, and his mother, thinking he was in a consumption," took him to an infirmary, where he remained six weeks. He had a slight cough at this time, which [illegible]

Digitized by Google

worse lately. He has also complained of his head "feeling queer," and that he has been unable to see at times. He has gradually lost flesh, and has become very weak, having fainted two or three times. His appetite has been good until the last two or three weeks, since which time he has taken but very little. His mother states positively that twelve months ago he was stout and well. He has never had any other illness, exhibits no trace of syphilis, and is of temperate and steady habits. His father died of phthisis. His mother is forty-eight years of age, "not very strong." She has had eleven children; four have died, one apparently from some cerebral or meningeal mischief, being eight years old; three younger children from "teething and bronchitis." There are seven other children alive and healthy; they all have dark complexions.

On admission the patient was in an extremely weak and prostrate condition, being unable to stand without support. His skin was cold, of a livid dusky hue; the fingers, lips, ears, and nose were blue; there was no pulse perceptible at the wrist, and the heart's impulse could not be felt or its sounds heard. He was immediately put to bed, hot water bottles applied, and stimulants given. In twelve hours or so the blueness passed off, and the pulse at the wrist could be felt, though it was still very feeble. The patient was thin, but not emaciated. The skin was of a dark-brown colour throughout, with here and there patches of deeper pigmentation, especially upon the abdomen and back. The penis and scrotum were especially dark, as also were the axillæ. Patches of lighter pigmentation occupied the knees. At the angles of the mouth and on the mucous membrane of the lips and cheek there were two or three purple-coloured patches. The tongue was coated with white fur; the bowels were confined. There were a few moist crepitations heard at the base of both lungs, mostly over the left. The heart's impulse and sounds were very feeble and indistinct, otherwise normal. There was nothing abnormal about the abdomen except some slight tenderness in the epigastrium. Urine acid; specific gravity 1012; no albumen. Temperature normal, tending to subnormal.

Shortly after admission the patient commenced to vomit, and though tried with various kinds of fluid nutriment, he eventually retained nothing. He was throughout remarkably dull and listless, never taking the least notice of what was going on around him; yet he answered readily when spoken to, and until the last had neither delusion nor delirium. Latterly he passed urine in bed, and his extremities became blue and cold. The pulse was again imperceptible at the wrist, and he gradually weakened, dying a week after admission on Dec. 20th. Two days before death the temperature rose to 102°.

A post-mortem examination was made by Mr. Arthur, surgical registrar, at 3 P.M. on Dec. 21st. Rigor mortis persistent; face and trunk deeply pigmented, also scrotum, penis, and inside of mouth. Left humerus shorter than right; pigmented scar below acromion. Some pulmonary œdema; no sign of tubercle in either lung; firm pleural adhesions at left base. Liver 48 oz. in weight; normal. Weight of heart, 6 oz.; normal. The right kidney weighed 5¼ oz., and was normal. The left kidney weighed 7½ oz.; also normal. Right supra-renal, much enlarged, weighed 1 oz., and consisted of a soft pale-yellow, cream-cheese-like substance. Left supra-renal, still larger, weighed 1¼ oz., and was of the some consistency as the right. Weight of spleen 10 oz.; of a pulpy gramous consistency. Testes normal. No disease of vertebræ.

Remarks by Dr. STURGES.—The case is deserving of record as a striking example of Addison's disease pure and simple occurring at an earlier age than is usual. By an unfortunate accident no microscopic examination was made, but the naked eye appearance, exhibiting yellowish caseous material softening down in places to creamy consistence, so as to hollow out the central part of the organs into semifluid masses, was sufficiently characteristic to remove all possible doubt as to the nature of the affection. So dark was the pigmentation about the face that at the first glance it suggested the seat of the malady. But the skin bronzing was hardly more striking than the asthenia. Weakening gradually day by day, there was absolutely no symptom save inability to retain food—neither fever nor sweating, nor diarrhœa. Strength went out of him, and so he died; that is the sole history, except, indeed that some hours before death he was delirious, and the temperature, hitherto about normal, rose to 102°. Both in colour and manner this boy recalled to my mind a patient of Sir H. Pitman's, a woman of forty, also a sort of gipsy, whose case, with others, I recorded in THE LANCET when medical registrar at St. George's Hospital many years ago.[1] This was also a pure example of Addison's disease, and the general condition would apply word for word to the present case: "Mere prostration; listlessness and indifference; frequent vomiting." It has often been observed that this rare disease is met with chiefly among poor out-door labourers much exposed to rough weather. The remark is strikingly confirmed by the fact that two typical examples can be quoted from among the gipsies in the experience of one observer. Furthermore, if any of us can claim equality with this tribe in the matter of exposure, it is, I suppose, the costermonger; and it will be found on reference to my paper that a fellow-sufferer with the woman just quoted—again a pure specimen of Addison's disease—was of that calling. Our late patient was but sixteen, exceptionally young. Dr. Greenhow's typical cases (forming Group I. in the appendix of his well-known work), collected from all sources, British and foreign, number 103. But of these only 14 are sixteen years and under; the youngest known examples being a boy and a girl each eleven years old. It is said, and truly, that the exposed parts of the body are the most liable to pigmentation, so that mistakes are made between the disease of Addison and sunburn. But it must be added that the parts least exposed to the sun, if exposed at all, are sometimes the most pigmented; not only the armpits and inside of the mouth, but the scrotum and penis, as with this boy and with the costermonger, or the anterior aspect of the thighs, as with the gipsy woman. For the rest, both the family and personal history of our late patient are chiefly negative. There was no associated disease, and the injury in childhood, from which he had completely recovered seven or eight years at least before illness began, can hardly be charged with any direct concern in the disease of which he died. Nearest to this obscure disease, as regards the silent fading of life without active symptoms, comes, I suppose, pernicious anæmia—no less obscure. And it is curious to reflect that the two affections brought together by this casual likeness are strongly contrasted in sex and habits. Anæmia prefers women and in-doors, and has small respect for social position. Addison's disease prefers men who lead rough lives out of doors, and are mostly poor and friendless. It spares the luxurious and the well-to-do. If it were a disease of the rich, like gout, it would probably be treated by more various methods, and more often receive kindly notice at the hands of quack advertisers, professional and other. Being as it is a disease confined to the destitute and to our general hospitals, and one which, but for hospitals and hospital schools, would probably have remained to this day unrecognised, there is a general consent, even amongst the most ingenious, that it is so obviously hopeless, that no word of profit can be said upon the subject of prevention, or treatment, or the means of discovering it at the pre-bronzing stage. Whether the unhappy subjects of the disease are yet greater sufferers on that account this is not the place to inquire.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

DISEASE OF KNEE-JOINT; DIPHTHERIA FOLLOWED BY EXTENSIVE PARALYSIS; RECOVERY.

(Under the care of Mr. EDMUND OWEN.)

The notes of the following case were taken by the late registrar, Dr. Chaffey.

H. S——, a boy aged six years and nine months, was admitted on April 14th, 1885. When eighteen months old his left knee-joint swelled without assignable cause. A year later he first underwent treatment, and during the next twelve months was twice under the influence of chloroform, and then some steel apparatus was applied to the limb, but without immediate improvement.

On admission the left knee-joint was stiff and flexed at a right angle, with some rotation of the tibia outwards. The limb was much wasted.

Three weeks after admission the child became the subject of diphtheria, characterised by false membrane on both tonsils, which were so swollen as to meet each other in the

[1] THE LANCET, 1864, vol. ii., p. 569. The supra-renal bodies in this case were described by Dr. Dickinson in the Pathological Transactions, vol. xvi., p. 243.

Digitized by Google

middle line, and by puffiness of the face and neck, and enlargement of the lymphatic glands of both sides of the neck. On the same day that the membrane on the tonsils was first detected, there was a trace of albumen in the urine. A week later the membrane on the tonsils and the puffiness of the face had disappeared, but the albumen in the urine had greatly increased, so that it amounted to as much as two-thirds. The child was never very prostrate, and after a week's illness he began to convalesce.

Sixteen days after the onset of the illness all signs of the diphtheria had apparently disappeared, except that there still remained a trace of albumen in the urine (this continued for six weeks longer); but on this day it was noticed that there was some difficulty in reading small print, the letters becoming confused. No other evidence of post-diphtheritic palsy, however, was then manifested. The next symptom was the loss of knee-jerk on the twenty-fourth day after the onset of the illness. This symptom persisted most markedly for two months and a half, and was still to be detected even three months later. On the thirtieth day the voice assumed a nasal twang, and the movement of the soft palate was found impaired; and some of his fluid food occasionally came back through the nose. On the forty-fourth day after the onset of the angina the voice was reduced to a whisper, no fluids could be swallowed, and the soft palate was absolutely immovable. All food (which was now administered entirely in the solid form) was vomited, and for twenty-four hours nutrient enemata had to be resorted to. Going back to the thirty-seventh day, the diaphragm was found to be contracting feebly, and on the forty-fourth day it had entirely ceased to act. The child's condition was now critical—with shallow irregular respirations, with an occasional ineffectual cough and very slight entry of air into the bases of the lungs; the heart's action was feeble, though regular. He was ordered one minim of liq. atropiæ every four hours. From the forty-fourth to the forty-sixth day the condition was extremely grave; although sensible, he was drowsy and prostrate, and bluish because of partial impairment of the intercostal muscles, in addition to complete paralysis of the diaphragm. From the forty-sixth day, however, he began to improve; the action of the diaphragm and intercostals returned, he was able to take food (at first solid, but soon thickened liquid food) by the mouth without vomiting and without regurgitation, and his voice became stronger and less nasal, and his power of coughing more effectual. Three days later the pupils were dilated, the skin of the face and chest flushed, and the child complained of thirst; he had been taking drop-doses of liq. atropiæ for five days. From this date he rapidly improved, and on the twenty-fifth day after the onset his voice had resumed its normal tone and strength, and there was no trace of albumen in the urine. The knee-jerks, however, still remained absent.

Throughout the child's illness there was no alteration of cutaneous sensibility, and the intensity of the palsy fell upon the muscles of deglutition and respiration. It was only on the forty-fourth day that weakness was found in any other muscles—namely, the external rectus of the left eyeball, and in certain facial muscles of expression. During the illness the left knee became nearly straight, and three months after his admission he was discharged with his leg in a Thomas splint, and getting about with a pair of crutches and a high boot. He returned to show himself two months later, when the limb was straight, though still wasted, and there were fairly free painless movements at the joint. At this time the knee-jerk was still feeble, otherwise no trace remained.

Remarks by Mr. OWEN.—It is hardly conceivable that a child could be more severely affected with diphtheritic paralysis than was this boy, and then recover. He had paralysis of muscles of vocalisation and deglutition; the stomach was so irritable that it could, for a while, hold no food; the diaphragm was completely paralysed, and the intercostal muscles, and even the heart itself, seemed to threaten cessation of action. If cardiac paralysis can be so often the cause of sudden death, even in children who are apparently convalescent from diphtheria, one had almost to expect its supervention in such a case as that just narrated. The occurrence of œdema of the lungs and pneumonia was also feared, not only because of the feebleness with which respiration was carried on, but also because of the risk of the passage of fluids through the paralysed glottis. The fact of the nerves of the pharynx, larynx, heart, and stomach all being affected betokens grave and extensive implication of the pneumogastric nerve; and the question is, of course, whether this implication was central or peripheral. Had opportunity for microscopic examination of the medulla unhappily occurred, it is possible that hæmorrhagic or disintegrating patches might there have been discovered, and so one might have been inclined to regard the paralysis as of central origin. But the temptation, on the other hand, is strong to accept Senator's theory of peripheral neuritis. Thus, the primary affection was of the palate, tonsils, and pharynx; nerves of these areas come from the pneumogastrics, glosso-pharyngeal, and sympathetic. The "neuritis migrans," as affecting the vagus, has already been referred to. The implication of the cervical sympathetic, extending through the carotid canal, reaches the ciliary ganglion (as shown by the loss of power of accommodation) and the abducens; whilst the partial paralysis of the facial nerves—a rare complication—would be explained through the association of the branches of the portio dura with the soft palate through the Vidian.

Medical Societies.

CLINICAL SOCIETY OF LONDON.

Contraction of the Metatarso-Phalangeal Joint of the Great Toe.—Acute and Chronic Internal Suppuration without Fever.—Glandular Swelling curable by Arsenic.

AN ordinary meeting of this Society was held on the 25th ult., Sir Dyce Duckworth, F.R.C.P., Vice-President, in the chair.

Mr. DAVIES-COLLEY desired to call the attention of the Society to the condition of Contraction of the Metatarso-Phalangeal Joint of the Great Toe, of which he had been unable to find any description in surgical writings. He had had five cases under his care during the last nine years. The disease consisted simply of flexion of the first phalanx of the great toe through 30° to 60°, with extension of the second phalanx, and some swelling and stiffness of the metatarso-phalangeal joint. All the cases were in young men. It seemed probable that later in life the deformity tended to change to hallux valgus. There was no paralysis of the extensor proprius hallucis, and, as far as he could judge, the flexors of the first phalanx and the plantar fascia were not primarily affected. The two causes to which he would attribute the condition were—(1) an injury to the joint, followed by contraction similar to that which is observed in the knee-joint; and (2) the pressure of short rigid boots upon an abnormally long great toe. The condition is very painful, and the patients walk with difficulty, resting their weight upon the outer border of the foot. In those cases he had subcutaneously divided the inner band of the plantar fascia and the short muscles of the sole about three-quarters of an inch behind their insertion into the sesamoid bones and first phalanx. All these cases were for the time cured, but one returned in two years in a still worse condition as regards flexion, with some outward displacement in addition—in fact, in an incipient state of hallux valgus. In this case a good result had followed resection of the metatarso-phalangeal joint. In two other cases he had excised the proximal half of the first phalanx, leaving the head of the metatarsal bone, with the sesamoid bones, and interfering as little as possible with the attachments of the muscles. Primary union had followed, and the patients were soon able to walk upon the flat sole. In one of them, twenty-two months after the operation, there was no appearance of deformity, and the patient had walked twenty miles without any difficulty on the day preceding. Mr. Davies-Colley would suggest that the deformity should be called hallux flexus, and that if the cases were too bad for treatment with rest and a splint, resort should be had to subcutaneous section of the muscles and fascia, or, in more severe cases, to the removal of the proximal half of the first phalanx.—Sir DYCE DUCKWORTH said that the subject of deflections of joints was interesting to him rather from the point of view of such constitutional causes as gout, rheumatism, and the like, than from such local causes as tight boots, whose influence in the causation was doubtful.—Dr. HERRINGHAM mentioned a case of the kind in a young girl aged fourteen. His colleague, Dr. Weiss, had also met with a similar case

Digitized by Google

He did not know whether the joints in all cases of deflection exhibited internal changes.—Mr. CHARTERS SYMONDS said that he had had many cases of derangement of this joint. The symptoms are pain, swelling of the joint and of the articular ends of the bones. It occurred in young boys, especially those with flat feet. Some of the boys had a long great toe. As to anatomy, there was no evidence of vascularisation of the cartilage; the changes were like those met with in the early stages of rheumatic arthritis. He thought that overwork of the joint was a cause.—Mr. CLUTTON inquired whether Mr. Davies-Colley considered that the deflection was due to muscular contraction. The ligaments seem to be the efficient causes of the deformity in "hammer toe," and he suspected that the change described by Mr. Davies-Colley was allied in its pathology, and was the outcome of subinflammatory changes, chiefly in the ligaments.—Mr. H. CAYLEY said that bare-footed races had the toes in a perfectly straight direction, although flat-foot was very common amongst the natives of India.—Dr. B. O'CONNOR thought that the extensor tendons had some share in the causation of the hallux valgus.—Mr. R. J. GODLEE said that in examination of three contracted fingers he had found the cartilage vascular and eroded where it had been in contact with the capsule. He had seen mild cases of this kind; the cause was unknown.—Mr. A. E. BARKER had removed a wedge-shaped piece from the inner aspect of the head of the metatarsal bone for hallux valgus. This would probably be a better operation than removal of a portion of phalanx, by which the joint would be opened.—Mr. DAVIES-COLLEY, in reply, said that at first he divided all the soft parts; the next time he performed complete excision of the joint; and lastly he decided on removal of the proximal half of the first phalanx. The cartilage of the joints frequently lost its pearly lustre and was fibrous-looking; the ligamentous tissue was thickened. The muscular contraction and the ligamentous condition were secondary to the joint derangement. None of the cases had flat foot.

Dr. SAMUEL WEST read some cases of Internal Suppuration, Acute and Chronic, without Fever. Case 1: Female, aged twenty-one, admitted with a swelling on the lower part of the abdomen and pelvis, with but little pain or tenderness. There was no history of acute inflammation. The swelling slowly increased, but the temperature was never raised; there were no rigors and no sweatings. The swelling was opened behind the peritoneum, and several ounces of fetid pus evacuated, after which recovery was rapid and complete. Case 2: Male, aged sixteen. Case of suppurative pericarditis (described in the Medico-Chirurgical Transactions for 1883), in which the pericardium was twice tapped and then laid open. The boy recovered completely. The temperature was never raised, either before or after the operation. Case 3: Female, aged ten. Case of suppurating peritonitis (described in the Clinical Society's Transactions for 1885). The case was very acute. The abdomen was opened, and fetid pus evacuated. The patient did not rally after the operation. The post-mortem showed the case was one of primary peritonitis. The temperature throughout was not raised. Case 4: Female, aged forty-eight. Abscess between liver and diaphragm and abdominal walls connected with the rupture of a duodenal ulcer. The temperature was not raised. Case 5: Male, aged thirteen. Case of empyema. Twice tapped, with removal of twenty-four and ten ounces of pus. Chest laid freely open. Recovery complete. The temperature was normal throughout. Cases 2 and 3 were very acute. In Cases 4 and 5 the development of pus was very rapid. Collapse was absent in all. Though the explanation is not forthcoming, the fact must be borne in mind, for forgetfulness of it may lead to error in diagnosis.—Dr. RYLE asked whether there was scope for the pus to move about in the cases in question; the tension of the pus in the abscess might influence the occurrence of pyrexia.—Dr. ANGEL MONEY suggested that an alkaloid, like antipyrin, might counteract the influence of the pyrogenic agent when acute suppuration did not cause fever.—Dr. CHARLEWOOD TURNER thought it was not the pus, but something, probably micro-organisms, in the pus, which were effective in the causation of the fever.—Mr. BARKER thought that information was needed concerning the causation of subnormal temperatures, occurring at times when usually a high temperature was registered. In a case of abscess of the brain a very low temperature was registered at that period in the evening when, with suppuration, it was most common to find high fever.—Mr. F. S. EVE agreed with the suggestion of Dr. A. Money, and thought that alterations in the state of the wall of the abscess might alter the conditions under which absorption took place. In some cases the stomata would become blocked, and the pyrogenic substance therefore less easily absorbed. The evidence available went to prove that no pus existed without the presence of micro-organisms. In suppuration without fever in serous membranes, the inflammation may be at first plastic, so that a layer of lymph is formed first on the serous membrane, and this may prevent absorption.

Mr. FREDERICK TREVES read a paper on a Form of Glandular Swelling which is cured by Arsenic. He drew attention to the obscurity that attends both the pathology and the clinical history of certain chronic glandular affections. These affections are covered by such terms as the following: hypertrophy of glands symptoms, malignant lymphoma, lymphadenoma, Hodgkin's disease, and lympho-sarcoma. These glandular swellings are considered to be uninflammatory, have no relation to scrofula or syphilis, and are clearly separated from the gland disorders that attend leukæmia. They possess the common characters of a slow origin without apparent cause, a slow but progressive growth, and an absence of all inflammatory phenomena. Histologically there would appear to be no means of distinguishing one of these affections from another. Apart from this, objection may well be raised to the terms hypertrophy and lymphoma. Without limiting himself to any special term, Mr. Treves desired to draw attention to the clinical aspects of a certain form of non-leukæmic gland enlargement that could be cured by arsenic. The patients are usually past middle age; they present no peculiar constitutional defect; there is no suggestion of gout, rheumatism, or scrofula. There is no leukæmia. The neck is usually involved. The gland tumours appear on both sides without disturbances in the periphery. The masses vary in size from a hazel-nut to a duck's egg. They are soft, elastic, homogeneous, movable, painless, and free from tenderness. They show a disposition to spread without limit. The temperature is normal, and suppuration does not take place. Mr. Treves gave instances of the cure of such cases by the use of arsenic. The drug is given in the form of liq. arsenicalis, commencing with a dose of five minims and increasing to twenty minims three times a day. The treatment has to be kept up for some months—one to six. The glands waste, some few suppurate, and in such instances the resulting sinuses heal without further treatment. In cases where the whole neck has been filled with great glandular masses the tumours have wholly disappeared after a treatment of from four to six months. Some of these cases, at least, would probably be covered by the term Hodgkin's disease. Mr. Treves concluded by an allusion to Dr. Köbel's paper on the treatment of malignant growth by arsenic administered by the mouth, and also hypodermically.—Sir DYCE DUCKWORTH was well acquainted with the disease. A process of disintegration rather than of suppuration was very liable to occur in the glands. Arsenic was very useful in some cases, but by no means in all. Injections of Fowler's solution were sometimes valuable, sometimes useless. Dr. Warburton Begbie had praised chloride of calcium in these affections. He did not agree that there was a paucity of literature, and mentioned the works of Trousseau, Gowers, and Southey.—Dr. STEPHEN MACKENZIE considered that the surgeon had usurped the province of the physician. In some cases arsenic was extremely useful, but in other cases of Hodgkin's disease it was useless, and the distinction between the classes could only be drawn by a trial of the arsenic.—Dr. PAYNE considered that these cases of multiple swelling of the glands, so well known to every physician and designated as Hodgkin's disease, could not be the same disease in all cases. Cases so diagnosed have been found post mortem to be caseous degenerations. A distinct poison or cause must have been at work, in many cases doubtless the tubercular virus. A giant-celled structure was often to be detected in the glands. Reference was made to a paper in the Transactions of the Pathological Society by Murchison.—Mr. ARTHUR DAVIES had had considerable success with the chloride of calcium, which, as Dr. W. Begbie had written, must be employed for a long period and in large and gradually increasing doses. Used in any other way the drug could not be said to have had a fair chance.—Mr. C. SYMONDS said that he had cured cases of the kind occurring amongst children and others by the employment of arsenic, but he knew of no characters by which to distinguish the remediable from the irremediable classes.—Mr. TREVES, in reply,

Digitized by Google

said that he alluded only to a certain class of cases occurring in persons of either sex past middle life, and in which there was no suspicion of inflammation about the enlarged glands. The suppurations mentioned only developed after the administration of arsenic had been begun.

MEDICAL SOCIETY OF LONDON.

Hereditary Tremors. — Random Symptoms from Cerebral Syphilis.—Facial Monoplegia.—Post-hemiplegic Chorea. —Jacksonian Epilepsy.—Ulceration of Palate.—Sarcoma of Tonsil.

A CLINICAL meeting of this Society was held on Monday last, Dr. Hughlings Jackson, F.R.S., President, in the chair.

Dr. SAMUEL WEST showed a case of Hereditary Tremors in a man aged thirty, in whom the fine movements of the hand were first noticed at the age of eight years. The father was "shaky," and died at the age of fifty-eight of paralysis. The tongue and ocular muscles were not affected. The tremors had the character of those seen in delirium tremens. The case was one of the same group shown by Dr. West last year.—Dr. EWART asked what Dr. West's views were as to the pathology of the tremor.—Dr. HADDEN said that the handwriting was a fair copy, and did not show signs of tremor.—Dr. HERRINGHAM alluded to the tremors that occurred in the hand after carrying heavy weights, and thought there was a resemblance to those seen in the man.—Mr. HILL said that the tremors were akin to those seen at the onset of the hypnotic state when artificially induced.—Dr. HUGHLINGS JACKSON thought the cases Dr. Samuel West described formed a group of family nervous diseases, other groups being Friedreich's disease, pseudo-hypertrophic paralysis, &c. He believed that the inheritance of a tendency to diseases was not that of a tendency to any pathological changes, but the transmission of small organs, of organs having too few functional elements. Insanity was often a family disease, and he believed that those who inherited a proclivity to it inherited a brain of which the functional elements of the highest cerebral centres were few. He could apply the same principle to the other family diseases alluded to, believing that some parts of the lower divisions of the nervous systems of those succumbing had fewer cells or fibres, or that in certain muscular regions there were fewer muscular elements. He thought that tremor always implied—that is, always coexisted with—paralysis. In the artificially induced tremor Dr. Herringham had mentioned, that from carrying something heavy, there was, he held, paralysis in the sense of loss of some movements of the hand and over-development of other movements of the same muscles—that is, tremor.

Dr. HUGHLINGS JACKSON showed a patient who had a random association of Nervous Symptoms from Syphilis. A man, thirty-four. Primary syphilis five years ago, followed by sore-throat; palate perforated three years ago. Fit of some sort five years ago. Present condition: No sense of smell; taste good; hemianopia; left fields blind [chart by Dr. James Anderson exhibited]; optic discs normal; slight distortion of the face to the left, with twitching in region of right zygomatici, and narrowing of the right palpebral aperture (relics of old Bell's facial paralysis?); paralysis and wasting of the right half of the tongue, with turning of its tip to the right on protrusion, and to the left when on the floor of the mouth; deafness of the left ear. The palate was fixed to the back of the throat, the communication of the mouth with the nose being by a hole. The random association of nervous symptoms would, Dr. Hughlings Jackson said, were there no direct and obvious evidence of syphilis, point to intracranial syphilis. With paralysis and wasting of one half of the tongue there was nearly always paralysis of the palate and vocal cord on the same side. In this case, for physical reasons, palatal paralysis was not demonstrable. Dr. Semon at the meeting examined the larynx and found no paralysis.—Dr. F. SEMON said that a cortical lesion involving the "phonation centre" could not cause unilateral laryngeal palsy. Stimulation of one centre in the cortex always caused adduction of both cords.

Dr. HUGHLINGS JACKSON also showed a patient recovering from facial Monoplegia of cortical or subcortical origin. A [illegible] who denied venereal disease, who had [illegible] disease, had an attack of numbness [illegible] for about five minutes one week before the attack on Feb. 8th, in which, with right hemiplegia, he was aphasic. One peculiarity of the case was the rapid disappearance of the paralysis of the limbs (two hours), and of the aphasia (about two days); the patient first regained "yes" and "no." When admitted (Feb. 11th) he had right facial paralysis and paralysis of the right side of the palate. He did not feel very light touches on the right hand, but did the prick of a pin. There was no paralysis of the vocal cord (Dr. Semon). The patient's speech (except that he was occasionally at a loss for a word), reading, and writing were good; his articulation was considerably defective. He had lost smell on the left side one month. The facial paralysis was more marked than Dr. Hughlings Jackson had ever before seen it from any destructive cerebral lesion. He exhibited photographs of the face taken by Mr. Stedman, showing among other things the great difference in the facial attitude between a "constructed" smile and a real smile when amused (a very important thing pointed out by Dr. Gowers). Dr. Hughlings Jackson had not seen such palatal paralysis as existed in this patient in any other case of cerebral facial paralysis, nor indeed in any sort of facial paralysis; it was as marked as the one-sided palatal paralysis occurring in (its usual association) cases of paralysis of the tongue and vocal cord. The uninstructed might have mistaken the case for one of Bell's facial paralysis with paralysis of the palate, a combination of symptoms he (Dr. Jackson) had not yet met with. The electrical reactions were normal. Dr. Hughlings Jackson did not hold the current doctrine of abrupt localisation, and considered that the transitory paralysis of the right limbs in this case showed that the part of the brain damaged represented movements of those limbs, although to a trivial extent. No doubt, too, the vocal cords are represented in the region diseased, but their escape is (Horsley and Semon) accounted for by their being also fully represented in the other half of the brain. That the vocal cords might act well when (Horsley and Semon) one of the two phonation centres was destroyed showed that there might be loss of (one half of) the *movements* of a region without disability in the *muscles* of that region.

Dr. SAMUEL WEST showed a case of Post-Hemiplegic Chorea, and described the character of the movements, their violence, the shortening of the leg, and the long interval between the hemiplegia and the hemichorea. The movements had somewhat the characters of athetosis. As the result of a fright by a dog the movements involved the face, and increased in violence.—Dr. HERRINGHAM said the movements had the character of "struggling."—Dr. EWART mentioned a case in a girl aged nine, which was congenital.—Dr. SIMMS said that sunstroke was very rare in the East Indies, and doubted whether this was the cause of the cerebral disease.

Dr. S. WEST also showed a case of Jacksonian Epilepsy in a woman. The fits began in May, 1885. She had had "pins and needles" in the left side. The fits had increased in frequency. The fit commenced with movements in the thumb and fingers, then the arm, then the leg, and the whole side twitched in the order mentioned. Some paralysis ensued on the fits. She had pain in the right side of the parietal region. There was double optic neuritis. The deep reflexes increased in degree. There was permanent left hemiplegia, involving the arm and leg. Did the lesion spread widely, or was it more deeply situate, and involving the fibres proceeding from the cortex?—Dr. HUGHLINGS JACKSON thought that there could be no doubt of the correctness of the diagnosis Dr. Samuel West had made. Optic neuritis, the best evidence of gross organic disease within the cranium, was not decisive of such disease. The kind of epileptiform attack the patient had did not necessarily depend on cerebral tumour; but the two things taken together, double optic neuritis and the epileptiform seizure, would make him feel as sure as he could be of anything medical that there was a cortical or subcortical tumour in Dr. West's patient. He urged that, since optic neuritis might exist with good sight, the ophthalmoscope should be used by routine in cases of nervous disease.

Dr. DE HAVILLAND HALL read two cases of Ulceration of the Palate and Pharynx occurring in young men aged nineteen and twenty-three. They were of syphilitic origin, and possibly of the hereditary variety.—Mr. LENNOX BROWNE referred to a case of ulcerated gumma of the pharynx, in which there was choroiditis and notched teeth.—Mr. MARMADUKE SHEILD referred to cases of disease in which the evidence of syphilis was slight, though it was certain that the disease was syphilitic. He suggested the possibility

Digitized by Google

of the dependence of the sloughing in some cases on a blood-poisoning not syphilitic.

Mr. LENNOX BROWNE showed a patient the subject of Lympho-sarcoma, which commenced in the left tonsil, extended down the pharynx, and invaded the larynx. The patient, who was under the care of his colleague, Dr. Dundas Grant, at the Central London Throat and Ear Hospital, had suffered from soreness and discomfort since the harvest of last year, and attributed his trouble to the irritation of the ears of barley. Deglutition was somewhat interfered with, but there was no distress in breathing, nor was the voice affected, though his articulation was somewhat thick. A large portion had been removed by the écraseur, Hartmann's forceps, Loewenberg's curette, and raspatory. Galvano-cautery had been afterwards applied. There was already slight recurrence, and a more radical attempt at removal was contemplated. Mr. Browne added that these cases were by no means so rare as generally supposed. Butlin could only collect nine in 1882, two of them being patients shown by Mr. Browne at the Pathological Society. The present was the third case which had presented itself within the last six months at the hospital, and the fifth case of malignant disease which he had seen in the past twelve months, one of the others being epithelioma. It was somewhat rare to see sarcoma of the tonsils extending so far down the larynx. It was a question whether the lymphatics ought not to be removed in any attempt at radical removal of the growth.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Urethral Calculus.

AT a meeting of this Society on March 4th, Mr. Benham read a paper on a case of Impacted Urethral Calculus, followed by Urinary Abscess; Perineal Section; complete recovery. W. W——, aged thirty-six, was just convalescing from a severe attack of double pneumonia when he drew Mr. Benham's attention on Sept. 26th last to the fact that his penis was much swollen, and that he was unable to micturate. He had a slight attack of gonorrhœa some eighteen years since, which lasted only for about seven days. He suddenly noticed a few months ago that the stream during micturition was smaller, and that the act was accompanied by a tickling sensation, almost culminating in pain at the root of the penis. The urine was normal. The author found the prepuce swollen, the upper portion being extremely œdematous and entirely obliterating the orifice of the urethra. The glans penis was much swollen, more especially towards the left side. After many unsuccessful attempts to pass a soft catheter, about three ounces of urine dribbled away, which gave relief; but on the following day, finding that the swelling had increased, including the scrotum, which was now about twice its normal size, that the retention was complete, and that the bladder was considerably distended, and as the author did not consider that there would be any advantage in aspirating the bladder, and as he believed that the operation of perineal section was necessary, he called Mr. Keetley in consultation. After Mr. Keetley had been unsuccessful in passing any instrument, it was resolved to lose no more time, and perineal section was forthwith performed. The median operation was chosen. There was considerable difficulty experienced in passing Syme's staff, which gave, when *in situ*, the sensation that it was in contact with some metallic substance along the side of the urethra, and on withdrawing it after the incision was made it was found that its lower or diminished portion had been literally bent from the straight line. A soft rubber tube was introduced through the perineal wound into the bladder and secured there, and linseed poultices kept constantly applied to the part. On the third day from the operation the œdema of the scrotum had somewhat subsided, but the swelling along the left side of the penis had considerably gained ground, giving a sensation to the touch of distinct fluctuation. An incision was accordingly made over the most prominent part, and about eight drachms of fetid pus evacuated. On passing a probe into the incision, it was found to go downwards into the œdematous substance of the scrotum, and upwards it communicated with the urethra. Poultices were kept constantly applied, and the cavities were frequently syringed with a weak solution of carbolic lotion, while the bladder was washed out twice daily with boracic acid lotion. Two days later, as the swelling had diminished, a metal instrument was passed from the perineal wound backwards along the urethra till it projected through the meatus as no instrument could be passed in the usual way. Then, by attaching the rubber catheter to the projecting metal one and withdrawing the latter, the soft catheter was pulled along the urethra, and so out of the perineal wound and then into the bladder. The rubber tube was subsequently replaced by a No. 9 gum catheter, as the former was constantly slipping out. This remained *in situ* a week, and then a No. 10 metal instrument was passed along the urethra from the meatus into the bladder; and in doing so, there again appeared a sensation of its coming in contact with some hard substance, but nothing definite was made out as to the cause. A week later, when all the swelling had disappeared, a thickening was found by the author around the urethra, just at the junction with the anterior margin of the scrotum. On passing a probe, it came in contact with a hard substance, which was broken into pieces and extracted with a director. By the beginning of November, both the wounds had healed, and the patient was himself able to pass readily a full-sized catheter.—Mr. KEETLEY said that the abscess was on the left side of the penis; no bougie or catheter touched the calculus. It was an open question whether the calculus was an impacted one, or whether it was a concretion lodged in a large lacuna.—Mr. PICK remarked that the case seemed to him one of gonorrhœa, followed by stricture and dilatation of the urethra behind the stricture, into which a calculus had passed. Had any symptoms of renal colic been noticed? He congratulated Messrs. Keetley and Benham on their case.—Mr. BENHAM replied.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

AT the meeting on February 17th, Dr. Cleaver, President, in the chair, the following papers were read:—

Thoracic Aneurysm.—Mr. COOMBE showed the specimens of a Thoracic Aneurysm taken from a patient, aged forty-six, under the care of Mr. Jackson in the infirmary. The aneurysm sprang from the anterior wall of the ascending and transverse portions of the arch of the aorta, and penetrated the chest wall to the left of the sternum by completely eating through one of the ribs. The patient was a scissors-forger, and had noticed the tumour forming for about twelve months, but had felt little or no pain or inconvenience from it. His family and previous histories were very good, and he had never had syphilis. The tumour ruptured by ulcerating through at a small spot externally, and the patient died about three hours afterwards, the bleeding being somewhat controlled by a gutta-percha cap, which was used as a support to the tumour. The diameter of the tumour was about four inches.

Aortic Disease.—Dr. DYSON showed specimens from two cases: 1. A brewer's drayman, aged forty-seven. During life a well-marked high-pitched musical murmur (aortic diastolic) was heard, and a thrill felt all over the front of the chest. At the post-mortem the aorta was very extensively atheromatous and the valves much thickened, but no cause was found to account satisfactorily for the musical tone of the murmur. 2. A woman, aged fifty-one, who had had rheumatic fever. The valves were much deformed, one being split down the middle, the segments being free to flap in the blood stream. The murmur in this case was a typical aortic diastolic one, with no musical quality. Both cases had Bright's disease, and died of uræmia.

Supra-pubic Suppuration.—Mr. ATKIN read notes of the case of a woman, aged twenty-seven, who had suffered from nearly constant vomiting for two months. She was very emaciated, and complained of great pain in the womb. Pulse 120: temperature 100°. She stated that the illness began with griping pains, followed by a discharge of blood from the vagina. Ether was administered, and the os found firmly closed, but soft, and the uterus not enlarged. Having emptied the bladder, an exploratory incision was made above the pubes, and a couple of ounces of fetid pus evacuated. The cavity proceeded backwards, lying over and roofing in the bladder. It was carefully drained, and the woman gradually recovered. Mr. Atkin drew attention to the anatomy of the so-called cavum Retzii described by Hyrtl, and commented on the existence of a space in the sub-peritoneal tissues. The doubtful origin of the suppuration, the lowness of the temperature, and the constancy of the vomiting were alluded to.

Digitized by Google

Plumbism.—Dr. PORTER, in introducing a discussion upon the subject of the prevalence of plumbism from the action of the Sheffield water upon leaden pipes and cisterns, alluded to Dr. White's exhaustive report to the Health Committee last year, directing attention to the danger at present existing, and spoke of his own experience in reference to its effects. He showed that out of a total of 1068 out-patients who had come under his own care at the Public Hospital and Dispensary during the past year, 14 had suffered from plumbism attributable to drinking contaminated water; while 13 more had presented a more or less defined "blue line," though treated for other complaints. Of these 27 cases, 3 had come from the country, away from the Sheffield water-supply; but of the remaining 24 no less than 16 patients lived in a district of the town, where the drinking-water had been shown by Dr. White to contain more lead than was the case with samples of water from other neighbourhoods. Dr. Porter also alluded to the prevalence of cases in the summer and autumn months, 17 occurring at that period of the year. In conclusion, he said that, in his opinion, the gravity of the danger had been underrated rather than exaggerated.—Remarks were made by Dr. Martin, Mr. Pye Smith, Mr. Garrard, Dr. Keeling, Dr. White, Dr. Dyson, Dr. Morton, Messrs. Reckless, and J. Williams.

Notices of Books.

The Croonian Lectures on some Points in the Pathology of Rheumatism, Gout, and Diabetes. Delivered at the Royal College of Physicians, London. By P. W. LATHAM, M.A., M.D., F.R.C.P. Pp. 123. Cambridge: Deighton, Bell, and Co. 1887.—The first part of this little work positively bristles with chemical formulæ, many of them highly complex and requiring the knowledge of an expert to understand their relationship to each other, and the significance of their presence in the body. It takes some time to pronounce such words as dimethyl-ketone-cyan alcohol, amido-diethyl acetic acid, and para-oxyphenyl-amido-propionic acid, and certainly an equal time to make sure that we are not thinking of some closely allied but not exactly identical body. The second lecture is occupied with the *materies morbi* in rheumatism. Starting with the lactic acid theory, Dr. Latham found that it was unsatisfactory, and was led to what he now considers to be the true cause of the disease by the perusal of Mitchell's work on the effects of injuries of nerves. He had noticed condition and circumstances which seemed to show that the central nervous system played a part in the phenomena of gout and rheumatism, and evidence gradually accumulated that the symptoms of these diseases were mainly owing to the presence and action of uric acid in the blood. He takes great pains to show how this acid may be developed by impaired digestion, and how, when circulating in the body as ammonium urate, it meets with sodium salts and forms sodium urate—the form in which it is deposited about gouty joints. His view is shortly expressed in these words: As in diabetes the essential fault lies in the inability of the system either in the liver or elsewhere to effect the metabolism of glucose, which then passes into the circulation and is discharged by the kidneys, so in gout or gravel the imperfect metabolism of glycocine is the primary and essential defect. Unchanged, it passes from the alimentary canal or elsewhere into the liver; then, under the action of the gland, it is conjugated with urea, resulting from the metabolism of the other amido bodies, leucine, &c., and is converted into hydantoin. It then passes on to the kidneys to be combined with other molecules of urea or biuret, forming ammonium urate, a portion of which overflows into the circulation, and is converted into sodium urate. He goes on to point out that the presence of uric acid in excess affects the vaso-motor centres, which, losing their tone or activity, cease to exert their proper influence over the vessels of certain tissues and regions of the body, and the symptoms of gout and rheumatism result. The practical application made by Dr. Latham of his theory is, that in the treatment of these diseases the formation of the urates is to be prevented as far as possible. The glycocine should be eliminated from the system as swiftly as can be effected, and he points out that this may be in part accomplished by the administration of benzoic acid, which seizes upon the glycocine or its antecedent, and passes out of the system as hippuric acid, in part also by the administration of salicylic acid, which he administers in doses of twenty grains till some physiological effects are produced. He places the patient on light farinaceous diet, keeps him cool, and prescribes some purgative medicine.

Diseases of Bones and Joints. By C. N. MACNAMARA, F.R.C.S. Eng., Surgeon and Lecturer on Surgery at the Westminster Hospital; Examiner in Surgery, University of Cambridge, &c. Third Edition. London: J. and A. Churchill. 1887.—This book first appeared in modest form as a series of actually delivered lectures; then it was somewhat enlarged; and now it comes to us as a big book, a systematic treatise on an important branch of surgery. Mr. Macnamara has read widely and worked hard for this edition; he has rewritten much, and added more, and has enriched his text with numerous excellent clinical records. The book is eminently readable, and is full of valuable information. Mr. Macnamara has long devoted special study to diseases of bones, and although we cannot endorse all his views, we are glad to welcome such a worthy expression of them. The engravings and woodcuts are good, and some excellent chromo-lithographs are a new feature in this edition.

The Treatment of Placenta Prævia. By JAMES MURPHY, B.A., M.D., Surgeon to the Sunderland Infirmary, Lecturer and Examiner in the University of Durham, Newcastle-on-Tyne. Printed at the *Sunderland Daily Journal* Office, Clayton-street.—Dr. Murphy has very properly published separately his paper on Placenta Prævia and its Treatment, read before the Northumberland and Durham Medical Society. We commend it to the careful study of all our readers, and especially of those who are engaged deeply in obstetric practice. Dr. Murphy is one of the most ardent advocates of early delivery by the induction of premature labour, "as soon as we know that we are dealing with a case in which the placenta presents, after the seventh month, and even before then, should the bleedings be serious, frequent, or continuous." His success may be estimated by a record of thirty cases, without one death. His views and methods are fully described in this paper.

The Journal of Physiology. Edited by MICHAEL FOSTER, F.R.S. Vol. VIII., No. 1. Cambridge Scientific Instruments Company, Cambridge.—This part contains four papers: 1. Jones Lloyd, on the Variation in the Specific Gravity of the Blood in Health. He measures it by drawing up with a syringe or by capillary attraction a little of the blood obtained from pricking the finger and discharging it into a mixture of glycerine and water of known specific gravity, and noticing whether it rises or falls. The effects of period of day, exercise, food and drink, &c., are given. 2. Sydney Ringer and Dudley Buxton, on the Action of Calcium, Potassium, and Sodium Salts upon the Heart of the Eel, and upon the Skeletal Muscles of the Frog. 3. Sydney Ringer, on the Action of Lime, Potassium, and Sodium Salts on Skeletal Muscle. 4. Pye-Smith: Observations upon the Persistent Effects of Division of the Sympathetic in the Cervical Region.

Burdett's Official Intelligence. Vol. V.—This book, which now enters upon its sixth year of publication, is too well known to stand in need of any description, or, so far as the

Digitized by Google

investing public is concerned, any recommendation. The mass of information which it presents is so vast, and the standard of accuracy attained is so high, that in its own department it enjoys an unquestioned pre-eminence. How large this department is may be gathered from an interesting summary inserted among the prolegomena, which gives the total amount, divided into various classes, of the securities quoted on the Stock Exchange. The aggregate comes out at the overwhelming figure of £3,098,182,369, or within a trifle of four billions sterling. All these are not only summarised in the volume before us, but every issue is separately scheduled, and minute particulars are given on all the points to which an intending investor looks. Mr. Burdett's book is, however, by no means only a vast schedule crammed with statistics. What we have above termed its prolegomena comprise a series of articles on fiscal subjects of general interest, which will prove not only a valuable repertory for the publicist, but also a most useful source of suggestion and information for the general reader. With this object the editor has made choice of such subjects as the progress of legislation or the course of public events has brought to the fore, and it seems to us that his selection has been justified by the happiest results. The present volume contains, among others, dissertations on such subjects of immediate interest as legislation as to railway rates and fares, gas prices and profits, tramway enterprise in the United Kingdom, and a review of the legislation of 1886. These and other kindred subjects are all treated with a fulness of information which will give to the articles a permanent value, while at the same time they are marked by a terseness and literary style which take them altogether out of the category of mere monographs.

Dictionary of National Biography. Edited by LESLIE STEPHEN. Vol. X. London: Smith, Elder, and Co.—The tenth volume of this Dictionary has just been issued, and extends from Chamber to Clarkson. Its contents, with regard to literary style and, so far as we have been able to judge, accuracy, are fully equal to those of the preceding nine volumes, upon each one of which at the time of its publication we have felt justified in bestowing high praise.

Ellis's Irish Education Directory and Scholastic Guide for 1887. Dublin: E. PONSONBY.—This Directory, now in its sixth year of issue, contains full information as to the Irish universities and professional schools, and the institutions in Ireland for promoting Intermediate, Technical, and Primary Education, with complete alphabetical lists of Irish colleges and schools and copious alphabetical and classified indices. By all interested in Irish educational work this book will be found useful.

Analytical Records.

KOLA PASTE.

(THOS. CHRISTY & Co., FENCHURCH-STREET.)

THE kola nut which comes from the West Coast of Africa contains in addition to starch, sugar, gums, colouring matter, &c., a considerable quantity of caffeine, and, it is said, some theobromine. Messrs. Christy and Co. prepare from it a cake resembling chocolate in appearance and to some extent in taste. It is made up with cocoa fat, is unsweetened, and by no means disagreeable. We have not as yet been able to submit the preparation to thorough chemical examination, but it is strongly recommended in heart affections and nervous depression, as well as in dysentery. Its introduction is interesting, and it certainly merits trial.

MALTINE WITH CASCARA SAGRADA; MALTO-VIBURNIN; MALTO-CARRAGEEN.

(THE MALTINE MANUFACTURING CO., BLOOMSBURY.)

The ever-active Maltine Company send us three more new combinations of maltine. Cascara sagrada, obtained from the bark of the Californian *Rhamnus purshianus*, is a valuable purgative and tonic. Dr. Garrod recommends it for chronic constipation, especially with hæmorrhoids. Each fluid ounce of the maltine contains one and a half fluid drachms of the fluid extracts. The usual dose is from a half to two fluid drachms. Viburnin is the greenish-yellow bitter resin of the *Viburnum prunifolium*. The peculiar constituents of malto-carrageen are yerbine, the active principle of the Mexican yerba santa (*Anemopsis californica*) and carrageen, or Irish moss. The mixture is emollient and expectorant.

EXTRACTUM PANCREATIS (Fairchild); PANCREATIC TABLETS (three grains); PEPTONISING POWDERS IN GLASS TUBES (five grains).

(BURROUGHS, WELLCOME, & Co., SNOW-HILL.)

BOTH the tablets and the tubes supply convenient means for the application of this well-known and valuable digestive agent. Each tube contains the quantity of powder required to peptonise sufficiently a pint of milk. We have tried this, following minutely the directions given, and in three-quarters of an hour the milk had in the faintest possible degree the peptonic taste. It was apparently but little changed, and we are convinced that infants would take it easily. When the milk stood for some hours complete peptonisation took place, and acetic acid no longer yielded a precipitate, but this is rarely necessary, and the bitter taste is a great objection. The tablets contain a convenient dose for use in intestinal indigestion; one or two may be taken an hour after meals. There can be no doubt as to the value of these preparations, or the trustworthiness of Fairchild's extractum pancreatis.

TARASP.

(RICHARD DAVIES, MADDOX-STREET, LONDON.)

Tarasp is a natural aperient mineral water. It contains, according to our analysis, 1166 grains per gallon of solid matter, which consists chiefly of chlorides, sulphates, and carbonates of magnesium and sodium. We also found calcium, potassium, and lithium, and a notable quantity of bromine. It is a very powerful aperient, and a complete analysis of it would be interesting.

DEODORINE.

(W. T. SMITH & Co.)

We have examined this preparation with great care, and have been unable to discover any advantage that it possesses. It is a neutral and very weak solution, containing only 0·337 per cent. of solid matter. Added in rather large quantities to a dilute solution of sulphuretted hydrogen, the smell was not destroyed.

DRY SPARKLING COCA WINE.

(CORBYN, STACEY & Co., LONDON.)

But that the coca taste is just perceptible, this might be taken for ordinary dry champagne. It is an excellent stimulant, and is well adapted for those who suffer from nervous exhaustion. It is evidently made from good champagne, with a small infusion of coca extract.

BRAGG'S PURE FLOUR OF EGYPTIAN LENTILS; BRAGG'S PREPARED BAKED FLOUR FOR INFANTS AND INVALIDS.

(J. L. BRAGG, WIGMORE-STREET.)

The microscope shows no trace of adulteration in these samples. They are exactly what they are described to be. The alteration in the wheat starch granules effected by heat is easily observed.

CONDY'S POWDER.

(CONDY & MITCHELL, LIMITED, TURNMILL-STREET.)

This is a powder containing a small proportion of alkaline permanganate. It has no smell, and possesses of course the advantages and disadvantages of the well-known Condy's fluid.

DE JONG'S PURE AND SOLUBLE COCOA.

(DE ERVÉ H. DE JONG, WORMERVEER, HOLLAND.)

This is an excellent cocoa, quite soluble in cold water, and free from starch and excess of fat. It is a very concentrated preparation.

THE LANCET.

LONDON: SATURDAY, APRIL 2, 1887.

THE Special Committee of the Senate which has been deliberating on the various proposals for reconstituting the University of London, that have been suggested by the Association for promoting a Teaching University for London, and by the Special Committees appointed by Convocation, has at length presented its report to the Senate for consideration and approval. The scheme laid down in this report will probably be adopted in all its important particulars, as it is recommended by a large and most representative committee including Sir E. FRY, Professor HUXLEY, and Sir JOHN LUBBOCK. It will therefore become the most important business at the ordinary meeting in May, unless a special meeting of Convocation be summoned for its consideration; but as an extraordinary meeting at an early date is already contemplated for the discussion of a communication from the Prince of WALES on the Imperial Institute, and for taking steps for the celebration of the jubilee of the University, the summoning of another special meeting is most unlikely and inconvenient. The new scheme differs from that drawn up by Sir E. FRY's Committee of Graduates, which would have materially increased the representation of the teaching element, and also from Sir P. MAGNUS's modified scheme, which was passed by the Graduates in Convocation, and may be looked upon as a *tertium quid*, and will probably satisfy neither the teachers nor Convocation. Its production is, however, a distinct proof that the present constitution of the University does not satisfy the most active and influential members of the Senate, and that the optimistic adulations of its work and mission which have already appeared, and which will be repeated *ad nauseam* in this its Jubilee year, are not looked on as quite justifiable even by the Senate itself. So far, the agitation for a local University in London has borne good fruit, and has justified its existence. The nature of the changes contemplated by the new scheme will be shown by a comparison of its proposed objects and those of the University as it now exists.

The original Charter of the University merely empowered "certain persons eminent in literature and science" to act as a board of examiners, and to confer degrees in all branches of learning, except Divinity, on students in University and King's Colleges and some other affiliated institutions named in the Charter; but in 1858 this restriction of studentship to certain colleges and schools was abolished, save in the case of candidates for medical degrees, and the University became an Imperial Examining Board open to all comers, collegiate or non-collegiate. In the scheme now proposed the purposes of the University are to be so defined as to include, "in addition to the existing purposes, the promotion of regular and liberal education throughout Her Majesty's dominions, and especially in the metropolis and its neighbourhood." Thus it aspires to do the duties of both an Imperial Examining Board and a local University. We cannot conceive of the possibility of its combining these functions. A local University promoting regular and liberal education in the metropolis and its neighbourhood must control and regulate studentship and curricula of study in the institutions within this area, whilst the present University can never return to its early mission and demand regular certificates of study from its candidates. Either these certificates must be a *sine qud non* before the degree can be conferred, as is the case in every university to which the name is properly applied, or they must be altogether dispensed with, as at present in the University of London. If teachers control the University definite courses of study will be imperatively laid down, and attendance thereon for a suitable period will be insisted on; whereas if "certain persons eminent in literature and science" continue to guide the fortunes of the University on the lines laid down by Lord BROUGHAM, and according to the views now predominant in Convocation, it must remain an Examining Board open to all the world. We fear these changes, not altering the character of the University, but merely, and to a small extent, its ruling body, by allowing certain restricted powers to representatives of associated Colleges, will only serve as an excuse to delay the formation of a real Teaching University in London. The details of these changes must be left for further discussion in our next issue.

WHAT is fever? This—which is the commonest and most constant indication of departure from health, which has in all time pressed itself upon the attention of the clinical observer—remains at the present day almost as mysterious as in the dawn of medicine. This ignorance certainly does not arise from lack of observation or experiment; and it cannot be said that hypotheses have ever been wanting. It must be conceded, however, that hitherto no sufficiently satisfactory explanation, which shall embrace the whole series of phenomena special to the febrile state, has been afforded. Nay, even as regards the cause of the one most striking phenomenon—the rise in the temperature of the body—there is no common agreement. It is not so long since the late Dr. MOXON, whose love of paradox was great, pointed out how little certain knowledge we possessed upon the nature of fever, in a lecture published in this journal (THE LANCET, Dec. 2nd and 9th, 1882). We felt bound to remonstrate with the line of argument he adopted, although there was some justification for it, since few subjects have been more at the mercy of theorists or made more the sport of ingenious minds. It must, therefore, be deemed a fortunate circumstance that we are enabled to review side by side the most recent teachings on the subject as developed in Dr. MACALISTER's Gulstonian Lectures and Dr. MACLAGAN's essay on Pyrexia and Hyperpyrexia, which have just appeared in our pages. The standpoint of the two is different, and their conclusions are not in entire accord; but they represent the outcome of physiological teaching upon animal heat, and each suggest, according to their respective views, hypotheses more or less satisfactory to explain the nature of fever. Of the two, Dr. MACLAGAN takes a somewhat wider view; whereas Dr. MACALISTER presents us with the conditions of the problem expressed in the terms of scientific analogy, and has, happily, availed

Digitized by Google

himself of the principles of evolution as expounded by HERBERT SPENCER and applied to pathology by HUGHLINGS JACKSON. There is, however, a more striking difference between their modes of dealing with the subject than this, and it is one which strikes at the root of the matter. To make it clear it will simply be necessary to briefly indicate the main lines of the respective theses.

Dr. MACLAGAN starts with the proposition that in fever the normal balance between tissue formation and tissue disintegration is disturbed. As results of the latter, he includes heat among the eliminated products like urea and carbonic acid, which are got rid of at the same time. But the balance between the production of heat and its elimination is maintained in health, and the temperature of the body is stable. He rejects TRAUBE's theory that fever is due to heat retention, showing that, except in the initial stage, such a condition would be inconsistent with the ordinary thermometric course of pyrexia, and that, as a matter of fact, there is increased elimination of heat, due, as he expresses it, to heat acting as a stimulant to heat elimination, on the same principle as carbonic acid excites respiration and urea excites the renal secretion. The hypothesis advanced by Dr. ORD, that in fever there is a liberation of heat which has been rendered latent in the process of tissue formation, is held by Dr. MACLAGAN to be inadequate to account for the excessive heat production that occurs. Again—and this is apparently the leading point of Dr. MACLAGAN'S essay—he contends that the phenomenon of hyperpyrexia is distinct in its origin from that of pyrexia; the "combustion theory" will not account for it; the nervous symptoms which characterise it are not due to the hyperpyrexia, but are indicative of the nerve disorder that produces it. Hyperpyrexia demands the intervention of the nervous system for its explanation; whereas, apparently, this is not necessary for the explanation of simple pyrexia. The thermic centre, which by the experiments of WOOD has been localised in the upper part of the medulla, exerts an inhibitory effect upon heat production; and if it be damaged or paralysed no limit is placed upon the extent to which the temperature, no longer regulated, may rise. This paralysis may be the result of undue stimulation, as suggested in heat apoplexy and in rheumatic hyperpyrexia, where Dr. MACLAGAN favours the view that there is increased muscular metabolism, and therefore increased heat formation, with the liability to over-stimulation of the thermic centre. Yet he does not see the necessity for adopting any such intervention of the nervous system in the case of other pyrexiæ. For their explanation, the neurotic theory is, according to him, superfluous. All may be explained, in the terms of metabolism, on the combustion theory. Thus in the specific fevers he will not admit that there is any toxic action on the heat-controlling centre to account for the disorder that is induced, but that the contagium consuming the store albumen intended for the repair of the tissues, and the water needed for tissue metabolism, is the indirect cause of the increased elimination of excretory products, including heat—the tissues feeding, as it were, upon their own substance, for lack of replenishment from the albumen normally destined for them.

We now turn to the doctrines enunciated by Dr. MACALISTER, we are enabled to see to what extent he has really succeeded in making a new departure, and in giving a new direction to our thoughts upon this subject. He starts from the same premises as Dr. MACLAGAN—viz., that in health heat production balances heat loss, and hence the stability of temperature; and that fever is essentially a disorder of body heat. But from the first he lays far greater stress upon the nervous mechanism, which of necessity must govern and regulate both heat production and heat loss. He does not, then, relegate to hyperpyrexia alone the disorder of this "thermotaxic" mechanism; it is the highest and most essential of the whole of the factors concerned in the maintenance of the body heat, it is the easiest to be deranged, and it is the uniting link of all pyrexiæ. This is a fundamental difference from such views as those expressed by Dr. MACLAGAN; but although the Gulstonian lecturer lays due stress upon it, he by no means limits his view to it, for the greater part of his lectures was occupied with the subject of thermogenesis or heat production. It may be noted that he rejects, like Dr. MACLAGAN, the retention theory of TRAUBE; and on the same grounds—viz., that in fever there is an abnormal discharge of heat, as shown by calorimetrical observation; although from the varying state of contraction of the cutaneous vessels the surface temperature is constantly varying. The nervous mechanism concerned in heat loss (thermolysis) is that of the vaso-motor and respiratory systems—each possessed of double functions, motor and inhibitory. Thermogenesis takes place very largely in the muscles, and is not dependent upon, although it may be increased by, their contraction; a fact which was demonstrated by experiment. But perhaps the most remarkable statements were those which sought to establish, with regard to thermogenesis, a nervous mechanism similar to that presiding over thermolysis. It is assumed, and to a certain extent borne out by facts, as it is supported by analogy, that this nervous influence is twofold: the one exciting to thermogenesis, and accompanied by destructive metabolism; the other inhibiting thermogenesis, and subserving constructive metabolism. In terms of metabolism, the former is catabolic, the latter anabolic; in terms of vaso-motor action, the former is motor, the latter inhibitory; in terms of muscular action, the former excites to contraction, the latter to relaxation of tissue. The grounds of this doctrine are fully set forth in the second lecture, and need not here be repeated. The evidence for the existence of special thermal nerves is but scanty. The thermogenic or catabolic nerves may be the same as the motor, but the statement by WOOD that the thermal centre was represented in the cortical motor area is based on inconclusive data; and the phenomenon of rise of temperature produced by ARCHINSON and SACHS on stimulation of the inner side of the corpus striatum seems to point to a tract distinct from that of motor impulses. It is on this tripod of thermotaxy, thermolysis, and thermogenesis, that Dr. MACALISTER bases his doctrine of the nature of fever, and explains the various forms of pyrexia by reference to the greater or less predominance of each of these processes. On this basis it is easy to agree with him that high temperature is not necessarily fever, and that fever is not necessarily accompanied by high temperature. "For if

Digitized by Google

"fever" we mean excessive thermogenesis, that may be more than compensated by excessive thermolysis; or, with a normal thermogenesis there may be diminished thermolysis; or the two processes may not act in harmony, and disordered temperature result from ataxy of the thermic centre, without any increased metabolism. By means of this doctrine—in which the neurotic theory that Dr. MACLAGAN reserves to hyperpyrexia is expanded so as to cover all variations in pyrexia—we seem to see more hope of harmony in our conceptions of the febrile state than we have hitherto conceived possible. For it embraces in one view the cases of paradoxical temperatures without accompanying fever, of which we have been familiar of late years; the cases of ordinary fever, where there is increased combustion of tissue and heightened body heat; and the cases where the whole mechanism is so deranged that compensation is no longer possible, and fatal hyperpyrexia is the result. Lastly, Dr. MACALISTER shows how, in accordance with the teachings of HUGHLINGS JACKSON, the lowest order of nervous mechanism—the thermolytic—is the most organised and most localised—viz., in the vasomotor, respiratory, and sudorific apparatus; the next—the thermogenic—is in a fair way to become more defined in its localisation; whilst the highest, but least organised and most easily deranged—the thermotaxic mechanism—is also the least localised. This may be taken, then, as the last, but by no means the final, word of physiological science upon the question; and we venture to think that it will give considerable impetus to a further study of a subject which, always full of interest, has such important clinical bearings. One word more in conclusion. Dr. MACALISTER took credit to himself for abstaining from reference to the bacterial pathology which dominates all teaching at the present day; still this is a question that must be reckoned with, and Dr. MACLAGAN did not hesitate to apply it to his views upon the nature of fever. Doubtless, however, Dr. MACALISTER thinks, and we are disposed to agree with him, that it will be better for us to attain to a clear notion of what fever is before seeking to explain the action of poisons or microbes in producing it. We are often too prone to seek for the causes of phenomena before we have determined the precise nature of the phenomena themselves.

PERHAPS the last meeting of the Ophthalmological Society, the full report of which we published on March 19th, was the most instructive, as it certainly was the most generally interesting, meeting of the whole session. It speaks well for the secretarial management of the Society that so much material relating to such closely allied subjects was thus happily collated; for the chief interest appeared to us to centre around the neurological papers and cases. Dr. BREVOR'S case of ophthalmoplegia externa was remarkable for the absence of other symptoms of nerve disease. What relation the nerve lesion might have to the "rheumatic fever" from which the patient is said to have suffered must necessarily remain obscure, and the obscurity is only increased when we reflect that "rheumatic fever" as a historical antecedent is often of a dubious nature. Mr. MARCUS GUNN'S case of a boy was chiefly interesting from the fact that when the eyes were turned to the left both pupils contracted, whilst in the lateral deviation to the right this unusual action of the pupils was not observed. Mr. J. G. MACKINLAY exhibited a girl aged sixteen with paralysis of the external rectus of each eye of congenital date, and associated with some errors of refraction and deafness on both sides. Not the least interesting was Dr. SIDNEY PHILLIPS'S cases of associated movement of the upper lid with movement of the eyeball. When the eyeballs were directed to one side the upper eyelids both drooped, though the drooping was less apparent on the side towards which the vision of the patient was directed; for the patient voluntarily hitched up the occipito-frontalis muscle on this side. As Dr. PHILLIPS suggested, it is exceedingly probable that in this case there was an unusual phenomenon of inhibition at work, the action of the nucleus that presides over the conjugate movement to one side suspending the normal tonic action of that portion of the nucleus of the third nerve which innervates the levatores palpebræ superiorum. Mr. JESSOP'S case was noteworthy in many points, but the phenomenon of hippus, or alternate contraction and dilatation of the pupil, irregular in time and degree, not related in time to the respiration, pulse, or nystagmus, was hardly less interesting than the circumstance that the movement of the images of objects seen by the patient was in the *same* direction as the ocular movements (lateral nystagmus). There seems to be a difference of opinion concerning this last point. It is maintained by some authorities that the apparent movement of the images of objects seen by the nystagmic eye should suffer displacement in a direction the very opposite of the ocular displacement. Dr. HUGHLINGS JACKSON'S case, reported some years ago in *Brain*, first drew prominent attention to this phenomenon, and he confessed himself at a loss to explain the reason why the movement of objects should, as the patient averred, go in the same direction as the eye itself turned. Dr. PRIESTLEY SMITH repeated the suggestion that the sudden jerk of the eye was of shorter duration than the slower return movement, and thought it possible that the image was properly perceived only during the return movement of the eye. But Dr. GOWERS certainly threw some light on the question in associating the phenomenon with the symptom of vertigo. In vertigo the sense of movement in the affected individual usually agreed, so far as the direction of the sense of movement was concerned, with the sense of movement which the patient experienced in regarding external objects within his visual field. The explanation of the agreement is to be found in the motor character of vertigo, and in the fact that any resulting movement of the patient is secondary and always falls short of the actual motor sensation experienced by the patient. As Dr. GOWERS argued: If a person turns round, and an object remains opposite to his eye, he infers that the object moves in the same direction as he does, and a sensation of movement leads to the same inference; actual movement would only prevent the inference that the object is moving in the same direction if it were equal to the tendency to movement, and there would only be a sensation of movement in the opposite direction if the actual movement were in excess of the tendency. Undoubtedly the most valuable paper of the evening was the one on conjugate palsy of the lateral movements of the eyes caused by disease of one side of the pons. Starting from the well-attested observation that

Digitized by Google

there is a nucleus or centre in each lateral half of the pons or its neighbourhood which presides over the conjugate movement of the eyes to one side—the left for the left, and the right for the right,—Dr. GOWERS classified three kinds of palsy from disease of the region in which this centre is situated. The centre was possibly the superior olivary body, which, as BECHTEREW has shown, is connected with the sixth nucleus, the auditory nucleus, the cerebellum, and the spinal cord. In the first class of cases there is palsy of the sixth nerve simply, from damage or disease of the fibres of the nerve as they traverse the pons; this leads to absolute inaction of the external rectus, and the eye deviates inwards. The second class is composed of cases of disease of the actual nucleus of the sixth nerve. As a result of it the associated action of the opposite internal rectus is lost, so that the eye could not be moved inwards were the patient told to look towards the side on which the lesion in the pons is situate. The third class of cases consists of those in which the lesion is above, say, the level of the left sixth nucleus. Then the lateral conjugate movement of the eyes towards the left is lost, but the left external rectus is not totally paralysed, for the eye does not turn inwards, as in the first two classes, but the nucleus of the sixth, being intact, appears to innervate the left external rectus sufficiently to keep up its normal tonic action. For a further exposition of the many ideas contained in this paper the reader should consult the abstract itself on page 578, where he may also find a full report of Dr. HUGHLINGS JACKSON'S philosophical remarks on the nature of nystagmus—a phenomenon which we think he rightly regards as indicating partial paralysis rather than "hypertrophy" of function, and thus the ocular shaking is drawn into the same circle as the tremor of the limbs in disseminated sclerosis, with which nystagmus is very commonly associated.

THE Royal Colleges exist primarily to supply the public with competent practitioners. When they are pressed with the argument that their refusal to combine with the Apothecaries will tend to the establishment of a competing body granting an inferior diploma on a less severe examination, they assent and say that that is just what is wanted. This is a very startling proposition, which requires close examination. The Royal Colleges, under the Medical Acts, are charged by Parliament with the duty, as we have said, of ascertaining that the entrants of the profession are capable of practising medicine, surgery, and midwifery with efficiency. They have higher functions, no doubt: they have the power of electing or examining persons who are to constitute a higher grade of the profession. But this is far inferior in public importance to their duty as examiners of the bulk of the profession. Take the College of Surgeons of England, for example. From last year's Calendar we gather that in the preceding year 51 candidates presented themselves for the Fellowship, while 1048 presented themselves for the diploma of Membership. The duty of the corporations to the public clearly has reference mainly to the hundreds rather than the dozens which they admit—to the Members, the holders of the minimum qualification, rather than to the holders of the honorary and higher grades. Now what is the simple duty which the corporations—acting conjointly, as they are required to do under the Act of 1886—owe to the public, and therefore to the candidates, for their ordinary diplomas? It is this—to examine them according to a standard which will "guarantee the possession of the knowledge and skill requisite *for the efficient* practice of *Medicine, Surgery, and Midwifery.*" This is the simple duty of the Examining Bodies. They have no authority in law to erect higher standards of examination than such as are necessary to supply the public with efficient medical practitioners for ordinary purposes. This will be equally the duty of any single corporation that may come to the Medical Council to ask for the appointment of "any number of examiners" that may be necessary for granting diplomas, conferring on the holders the right of registration under the Medical Acts. The Apothecaries will have no other, and certainly no lower, duty than that imposed on the Royal Colleges. What becomes, then, of the argument of the advisers of the Royal Colleges, that a lower grade of practitioners is wanted, and a lower body wanted to diplomatise them? Where is the Act of Parliament that empowers the Royal Colleges to attach to their common diplomas the condition of higher knowledge than that which is sufficient for practice? Where is the Act of Parliament that recognises the right of the Royal Colleges to depute their work to a lower body, or practically to risk the creation of a lower standard than that which guarantees competency? The Royal College of Physicians has once before in history made this great mistake. For half a century it was estranged from the bulk of the profession in England. It seems strange that it should be again unpractical and above its business. But it is said that the poor cannot pay for a properly qualified physician and surgeon; they must have something less. This is a dangerous doctrine. What should we have thought if it had been embodied in the Medical Act?—if, after Clause 3 had defined the duty of the medical authorities to hold examinations on standards which should guarantee competency in those intended to practise among well-to-do people, there followed a Clause 4 to provide diplomas not guaranteeing competency for a class of persons to practise among the poor? This is of course a *reductio ad absurdum.* But it is precisely what many prominent members of the Royal Colleges are thinking, and even saying. The doctrine cannot be maintained seriously. The diseases of the poor are not different from those of the rich. An error of diagnosis or of treatment is as disastrous in them as in the rich, and even more so. They have plenty of cheap physic from quacks of all sorts. The law recognises no distinction in the qualifications of the medical advisers of the rich and the poor. If the Royal Colleges promote such distinctions, they will do their best to violate the law and to degrade the profession.

ON Monday last a Scottish deputation waited upon the Marquis of Lothian and the Lord Advocate to urge that in any Bill proposed by the Government for the management of lunatics in Scotland, care should be taken that the districts be small, and that the governing bodies be elected by the ratepayers. The Marquis expressed entire sympathy with the views of the deputation with regard to the importance of the districts being of small size.

Annotations.

"Ne quid nimis."

THE ERASMUS WILSON BEQUEST.

THE profession has been informed by the daily papers that on the day preceding the last meeting of the Council of the Royal College of Surgeons the President received at the College a deputation of anti-vivisectors, who handed in two memorials got up in opposition to that recently presented to the Council by the teachers of surgery in London. The fact has excited a good deal of comment, and ought not to be allowed to pass without notice. It is important to know whether the Council of the College endorses and approves the action of the President. It is the general opinion that a deputation of this kind, and on such an errand, should only be received officially. Did Mr. Savory speak on this occasion as the President of the College or did he not? Surely this point ought to be cleared up. As to the general question of the method of the appropriation of the bequest, we repeat if the Council refuses to listen to the urgent request of the teachers of surgery, and spends on bricks and mortar, casts and drawings, money which could be used in facilitating scientific research, it will show itself singularly out of touch with the profession. It must be remembered that the laboratory asked for is not for vivisection only or mainly, but for the encouragement and conduct of all means of investigation and experiment which have for their aim the advance of surgery and the prevention and cure of disease.

RELATIVE RANK IN THE ARMY.

LAST week a deputation from a committee of the British Medical Association waited upon the Secretary of State for War, to bring under his consideration the subject of relative rank in the case of medical officers of the army. It was introduced by Sir Guyer Hunter, but the case was stated fully by Surgeon-General W. C. Maclean, Emeritus Professor of Military Medicine at Netley. He explained that a strong feeling had arisen in the Department that the abolition of the term "relative rank" had deprived the medical officer of any status he had in the army, and that unless this were removed the effect upon the supply and the quality of candidates for the service would be most disastrous. He concluded by saying that "the authorities having now declared, in the most positive manner, that relative rank was a mere term, having no value at all, it would never satisfy the Army Medical Service to have relative rank restored to its former position. The medical officers of the army rendered great services to the State, and he thought it was only fair that they should respectfully ask to be placed on the same footing as the Pay and Commissariat departments." He was supported in his views of the effects of the change, as regards the candidates, by Dr. A. Carpenter and Mr. Macnamara. Dr. Clarke, M.P., thought that "if any change were made at all, it should be to give the medical officer actual instead of relative rank. Unless one or the other were given, it would seriously injure the supply of medical men to the army." The Secretary of State in his reply assured the deputation that the War Office, in issuing the warrant, with which he had not been personally concerned, had not the least intention to alter the position and precedence of medical officers. He owned himself very much puzzled now to know what the medical officer has lost, but admitted that "there is a sentiment at the bottom of it all, and sentiments are things to be reckoned with very much in these days." He promised carefully to reconsider the terms of the warrant, and take care so to word them that "it shall be made pretty clear that you have not lost anything whatever by the change which has been introduced into the warrant." Accepting the assurances of the Secretary of State and of the Director-General, we have always held the opinion that there was no real cause for this scare. As, however, the declarations referred to have not had the effect of reassuring the medical officers, and some step is to be taken to make it clear that their rank in the army is not to be interfered with, the question is, How can this be done in a manner which will prevent discontent? Dr. Maclean has suggested that honorary rank should be given, as in the Pay and Commissariat branches of the service, while Dr. Clarke is of opinion that actual rank should be conferred on them, that in fact they should sink their professional title in their military. We feel sure that the latter course would not prove acceptable to the best class of medical officers, who, as a rule, take a legitimate pride in their standing as members of a scientific profession. There is yet another course which might be taken by the War Minister—the issue of a Royal Warrant declaring the various grades in the medical service to be in all respects equivalent to, and carrying with them all the privileges and advantages of, the corresponding military grades with which they were classed under the preceding warrant. This would give a defined military status to each grade of medical officers, which it would be impossible to call in question or in any way to set aside. The medical officers form an integral part of the army, and it seems absurd that their position in the military machine cannot be defined without dubbing them colonels, majors, and captains.

A SLEEP OF SIX DAYS.

THERE is no more mystery about the case in Soho, that has attracted so much attention, than there is about many another interesting and imperfectly understood medical phenomenon. Through the courtesy of Dr. Keser we were enabled to examine the patient. The following is an abbreviated account of the patient's present state. The man is about the age of thirty-five, a good-looking Frenchman, who was lying on his back with his eyes closed, his countenance slightly flushed, and, at a casual glance, apparently in quiet sleep. Examination proves beyond doubt that the sleep is profound—that, in fact, there is a total abeyance, abolition, or loss of consciousness, or of the highest functions of the cerebral cortex. This sleep has not been broken since it began, now seven days ago. During the whole of the time the patient has not given the least sign of intelligence. If one eyelid be raised and light from a mirror thrown in, the other eye opens, the pupils contract, and the patient seems to be attending to the light, his eye apparently fixing something. If the light be withdrawn the eyes remain open for some thirty seconds, but closure of one is rapidly followed by shutting of the other, and the patient returns to his usual state. The pupil sometimes shows the phenomenon of hippus, alternately contracting and dilating whilst the light is thrown on the open eye. The orbicular muscles are slightly contracted (normal tone). The mouth is tightly shut, and the teeth clenched by the tonic contraction of the muscles supplied by the fifth nerve. Occasionally slight spasms seize the individual facial muscles. A tap on any muscle usually leads to tonic contraction of it. If the arm or leg be placed in ever so awkward a posture, it remains there for several minutes before a tremor commences in it. The limb when placed in a certain posture is rigidly fixed by tonic spasm. Shampooing a rigid limb has no effect on it. A sudden blow, as a rule, does not disturb the rigidity, nor does a very gentle stroking of the skin relax the spasm. But a smart "glissade" movement with the palm of the hand is usually followed by fall of the limb and cessation of the spasm. This is most effectual when applied to the

Digitized by Google

flexor surface of the arm and the corresponding surface of the leg. The knee jerks are somewhat exaggerated. At times an ankle clonus can be obtained. The superficial reflexes appear everywhere to be diminished. Scratching the skin is soon followed by the appearance in the scratched area of well marked "goose skin," and later a red tache cérébrale appears. At times this cannot be obtained. At other times a white streak marks the area irritated. The skin is moist and warm everywhere. There is no local sweating. The temperature varies from 97·6° to 98·5°. There do not appear to be any areas of elevated temperature. The bowels have not acted since the hypnotic state began. But little urine has been secreted; this has had to be drawn off by the catheter. There is no evidence of emaciation. The patient has to be fed by his attendants, but the food poured into the throat is usually neatly swallowed, and does not cause choking. The breathing (18) and pulse (72) are regular. There is no œdema or vomiting, and the veins and arteries are natural and soft. The daily discharge of urea has not been estimated at present. The urine is acid, and contains a trace of albumen, but no sugar. Little is known of the previous history, but it is certain that he has suffered from somewhat similar seizures, for he has been a patient of M. Charcot at the Salpêtrière. The condition of the patient cannot be explained on the assumption of any form of toxæmia, or coarse organic brain disease.

THE JUBILEE ODE.

THIS Ode consists of eleven stanzas, and is not unworthy of the occasion. We gladly welcome the Laureate's recognition of fifty years' marvellous progress in Medicine in the second line of the following three:—

> "Fifty years of ever-broadening Commerce!
> Fifty years of ever-brightening Science!
> Fifty years of ever-widening Empire!"

We like, too, the following summons in Stanza vi. to all who are capable of making the Jubilee real and happy, and are especially glad to number Lord Tennyson among those who would send gold in heavy quantities to the hospitals:—

> "You that wanton in affluence
> Spare not now to be bountiful.
> Call your poor to regale with you;
> Make their neighbourhood healthfuller.
> GIVE YOUR GOLD TO THE HOSPITALS;
> Let the weary be comforted;
> Let the needy be banqueted;
> Let the maimed in his heart rejoice
> At this year of her Jubilee!"

THE TREATMENT OF LEPRA MACULOSA.

DR. EGEA, one of the physicians of the Hospital Juarez in Mexico, writes in the *Gaceta Médica de México* that a second year's student named Rodiguez, having suggested from previous experience a trial of a decoction of a mallow common enough in Mexican gardens, and called *bola de fuego* (fire-ball), in a very bad case of spotted leprosy, Dr. Velasco, under whose care the patient was, consented to use it, with the result that the ulcers healed within a month, the diarrhœa ceased, and the patient recovered. Dr. Egea then tried the same remedy on a patient of his own, who was suffering so severely from the same form of leprosy that he could scarcely move in bed for the terrible pain which motion caused, the surface of his body from head to foot being simply one great ulcer, the foul odour from which no amount of carbolic lotion or ointment was able to destroy. When he had taken the mallow for a fortnight the legs had healed, and in a month's time no ulcerated surface remained on the whole body. The patient's whole condition, too, had improved so much that he was able to walk about. The decoction was made by boiling a handful of the leaf in a pint of water, which quantity was given daily at first, being gradually increased until two pints were given daily. The antiseptic local treatment employed did not appear to have any effect. Dr. Egea says that the spotted form of leprosy (Lepra maculosa) was first described in 1851 by a Mexican physician, Dr. Lucio, and afterwards in a somewhat meagre manner by Hebra, but that by far the most complete account of it is due to the labours of Drs. Lucio and Alvarado. It is mentioned by Fagge and shortly described in Littré's "Dictionnaire de Médecine."

OVERCROWDING OF WORKHOUSE INFIRMARIES.

THE inclement weather experienced during the greater part of March has filled our hospitals and infirmaries to overflowing. Already Dr. Steele has written to explain how it came about that they were unable to retain a man with a fractured leg for more than one night at Guy's Hospital, passing him on, owing to their overcrowded state, to the Workhouse Infirmary. It was reported at the last meeting of the Lambeth Board of Guardians that there were eighty-seven men and forty women in excess of the certified number, and that some of these were actually lying on the floor and others on tables. It is matter of regret to find year by year the accommodation afforded to the sick poor becoming proportionately less and less, as the hospitals, owing to their diminished resources, are compelled to close more and more wards. The fact that the present generation has not been able to keep pace with the charitable requirements of the day is a deep reproach to those who are spiritual instructors and teachers of morality. The falling off in the funds of charitable institutions is not owing solely to diminished subscriptions, which might be accounted for by the existing depression of trade, but to the noble legacies which in time past were such a distinguishing feature of English charity. It is sad to read week after week of enormous fortunes left, and so little devoted to charitable uses. An evening contemporary has brought this forward in a striking manner recently, by tabulating weekly the wills proved, and noting the amounts therein devised for charitable purposes; and on looking over these tables, it is astonishing as well as depressing, in spite of noble exceptions, to see how little the very wealthy members of society seem to think on their death-beds of the claims of the suffering poor. This neglect of the primary duty of promptly relieving the sick and needy is a great mistake, even from the purely practical point of view. Every artisan or able-bodied labourer who becomes a chronic invalid, owing to neglect in the first stages of his disease, becomes a burden on the rates; whilst every family driven to take shelter within the walls of the workhouse swells that great army of paupers which is progressively and surely sapping the vitals of national prosperity.

PANICS IN THEATRES.

MR. WILSON BARRETT and Miss Eastlake, by a little presence of mind—neither more nor less than the amount requisite to extinguish the flame of a candle which accidentally fell from its socket on the stage, "away from any inflammable material," and to resist the impulse to be scared by the yells of an idiot who raised a cry of fire in the auditorium—succeeded, on a recent occasion, in averting a panic. Mr. Wilson Barrett afterwards lectured the audience on their folly. Perhaps it was hardly worth while to do this, seeing that people will always be terrified by cries of fire, and no amount of argument is likely to prevent their behaving like maniacs when under the influence of fear. Meanwhile, it is a fact beyond question that, with very rare exceptions, the catastrophes in which panics culminate are wholly causeless and wanton. We are not of those who think much good will be accomplished by dissertations on the subject of timidity. In spite of all that may be

Digitized by Google

written or urged against impulse, and in praise of self-possession, the majority of persons in any place of assembly, especially if it be crowded, will try the chances of escape, either for themselves or those dear to them, and probably struggle and "rush" in an ugly fashion to accomplish their immediate purposes. It is vain to try to dissuade individuals from adopting this policy, unless it can be made certain that a patient and wise man will not find the places of exit choked and impassable when at length he thinks it prudent to decamp. Of course *if* only everybody would be calm and make a dignified retreat, there would be no difficulty. Few buildings—except some of the older theatres and those which have been recently spoiled by the interference of the Board of Works—could be destroyed before their audiences retired if the exit were orderly, but it must be avowed that as the human brain and nerves are constituted those who depart are little likely to stand upon the order of their going, and will be solely concerned to go quickly. Practically, therefore, it amounts to this, the safety of the public must be secured by measures over which they have no control, and it is really no good rating them for the terrorful impulsiveness. The one, and only, preventive against panic is the avoidance of such stupid "accidents" as the falling of candles from their sockets. It seems to us rather hard on an audience to be scolded for showing signs of impending panic after being frightened by the falling of a candle, which must have been carelessly or indifferently stage-managed, and then scared by the shouts of an idiot.

LONDON DUST.

IT is now many years since dust contractors were willing to pay for the privilege of removing house dust. The days of the golden dustman are past, and London vestries are compelled to pay large sums annually to contractors, who, after removal of the refuse, have been only able to turn it to account by the manufacture of bricks and the manuring of land. But even these businesses are not carried on at all periods of the year, and hence the contractor has at times, when he has no opportunity for its use, often neglected to rid his district of accumulations prejudicial both to health and comfort. In some instances vestries have determined to organise their own arrangements, and to deprive the contractor of a duty which at the best of times was ill-performed. Under these circumstances new methods of dust disposal were sought, and attention was naturally directed to the north of England, where successful efforts had been made to destroy house refuse by fire, and to use the resulting material for the manufacture of mortar. In 1880 the vestry of St. Pancras, moved by a report of their medical officer of health, determined to send a deputation to the northern counties to see for themselves the methods which had been pointed out to them; and as a result a strong recommendation was made to the vestry to relieve themselves, by the erection of a destructor in an outlying part of the parish, of the difficulties in which they were constantly placed. From circumstances incidental to parochial government no further progress was made, but shortly afterwards a similar recommendation was brought before the Commissioners of Sewers by the medical officer of health of the City of London. More recently the Whitechapel Local Board have succeeded in the erection of one of these furnaces, and the Kensington vestry were some two years ago desirous of adopting the same course. They progressed so far as to order a Bill to be laid before Parliament, authorising them to acquire land compulsorily for this purpose; but the proposal has not met with continued favour, and, as the result of the support they accorded to it, so many of the vestry-men have lost their seats that there is now a majority on the vestry against the original scheme. Nevertheless, we believe the time has come when the new system must be adopted; the old has certainly failed, and refuse removal must be made independent of trade requirements. It is therefore with much satisfaction we learn that the Kensington Vestry Bill has been read a third time, and we hope that this body will not hesitate to utilise their powers, and at once provide the necessary apparatus. This is to consist of a "Fryer's destructor," having twenty fire-places or cells, with inclined hearths and reverberatory arches. The dust will be carried in carts up an inclined roadway to the top of the furnace, where it will be precipitated through trap-doors on to the fires below. A flue from each cell will join a common flue, where the products of combustion will be burnt, and will eventually escape through a chimney-shaft 180 ft. high. The slag will be used for mortar and for road foundations, and the heat for working machinery for washing and screening road sweepings, the grit of which will also be used upon the roads. It is calculated that at a cost of eightpence each cubic yard of road sweepings will produce material worth five shillings per yard, while the furnaces would further be capable of working machinery which would illuminate the whole parish with electric light. Objection was taken in the House of Commons to a method which it was urged by the opponents of the scheme would give rise to nuisance; we believe this fear is illusory, and we should gladly see success attend an effort to deal with one of the most difficult problems that London has yet to solve.

INFECTING WHITLOW.

DR. ESTÉBAN BORRERO ECHEVARRIA, writing in the Havana medical journal *La Enciclopedia*, mentions the case of a young woman of twenty-three, badly nourished and ill developed, appearing like a girl of sixteen, who had a whitlow commencing in the middle joint of the middle finger of the left hand, which, being neglected, went on to produce caries of both the distal phalanges, with serious deformity of the finger. In about two months after the commencement of this whitlow another formed in the second and third joints of the ring finger of the right hand. She then presented herself for treatment. Dr. Echevarria promptly opened the whitlow down to the bone, and this healed satisfactorily; however, in about a fortnight a third whitlow formed in the ring finger of the left hand. This was also opened. These three whitlows were all quite idiopathic. The writer does not attempt to explain the succession of these inflammations, but suggests that they may be considered as all due to a general vice affecting the whole system, or to infection through unnoticed abrasions of the skin by pus. Some, he says, may consider the case as one of infectious osteomyelitis, but at all events he gives the facts as showing the existence of osseous panaris (*panadizo óseo.*)

ILLNESS AND SCHOOL ATTENDANCE.

WE would be foremost in asserting the vital necessity of education, and we are well aware that the most resolute efforts directed towards this end can effect but little without regularity of attendance. Happily, under the present compulsory system, assisted as it often is by pecuniary aid for the payment of fees in really necessitous cases, absence from school can hardly be excused on any pretext but that of illness. This cause alone, however, must almost everywhere much impair that continuity of teaching which is so desirable. Not only does it act by affecting the health of scholars themselves, but hardly less when it touches other inmates of their homes. A child may be well himself and yet be inadmissible in school if he come from a house where infectious disease prevails. Such con-

Digitized by Google

siderations, without reference to others less connected with the province of medicine, obviously render a perfect annual attendance in any school a practical impossibility. We are accordingly astonished to find that in one case—that of the Manchester Free School—the absences of children from every cause during four years have not on an average exceeded so low a ratio as 1 in 80 of those enrolled. Nothing could be more satisfactory than these statistics, were it not that the Free School in several respects occupies a unique position. Regularity of attendance appears to be its most cherished principle. Whatever interferes with this is by every possible means to be removed. Among other causes for the withdrawal of children the school reports mention "personal or domestic sickness." Does this mean that children who are absent for a certain number of days on account of illness are *ipso facto* expelled from school? If so, it would be easy on the same system to secure great regularity without a corresponding gain to education. It is difficult to see how by any other process the diseases of children can be made to affect so little the continuity of their school training. We have no wish to over-state the case on the medical side, but we are strongly of opinion that it is the duty of educational authorities in general, and of each schoolmaster in particular, while sufficiently critical as to the reality of excuses on the score of health, to see that due allowance is made for unavoidable illness, however this may affect the roll of school attendance.

CATARACT INDUCED BY THE VIBRATIONS OF TUNING-FORKS.

DR. S. TH. STEIN, in order to examine the functions of the cochlea, acted on the eyes of very young porpoises, both in the unmutilated state and after the ears had been destroyed, by means of the vibrations of tuning-forks of different pitches. Cataract was produced in both classes of experiments. In the entire animals continuous subjection to the action of a high-pitched tuning-fork induced cataract in from eighteen to twenty-four hours, while a tuning-fork vibrating 100 to the minute produced the same effect in twelve hours. In animals whose ears were destroyed the cataract was much more quickly induced by the tuning-fork, some two or three hours being then sufficient. Dr. Stein's theory is that the condition of the lens is affected by the giving off of heat from the body, and that this is altered by the vibrations, the perception of sound again tending to retard the development of cataract. The members of the Moscow Medical Congress, before whom Dr. Stein related his experiments, did not appear inclined to accept his theories; and Professor Khodin remarked that it was not an uncommon thing for young porpoises to be born with cataract. To this, however, Dr. Stein replied that the cataract produced by his tuning-forks passed off after a time, and could then be re-induced by the same method.

QUARANTINE AT MARSEILLES.

THE reappearance of cholera in Southern Italy will give a good deal of employment to the Marseilles port sanitary authorities. This town, though itself one of the most unhealthy ports in Europe, is ever taking extraordinary precautions against the importation of disease. It possesses a magnificent quarantine station, which we recently visited. Two islands joined together by a breakwater form a harbour where the largest ships may be detained during the worst weather. On one side of the bay or harbour is a huge shed for the disinfection of rags. Close at hand are other sheds for the disinfection of mails, personal luggage, and furniture brought by passengers. On the other side of the bay a great number of houses can shelter many hundred travellers. Of course the drainage in these houses is not in a satisfactory condition, though during 1886 considerable improvements were made, and quarantine was imposed on ships coming from Italy, Austria, and the Brazils. The greater number were only detained for twenty-four hours. Indeed, it was a medical examination rather than a quarantine. Other ships had to remain at the station three days, and a few as long as five. Some idea of the service, to say nothing of the inconvenience, involved will be gathered from the fact that the number of passengers and sailors detained amounted in all to 28,000. Many of these persons belonged to the poorest class of Italian labourers; and if during their stay at the quarantine station they could be made to take baths and have all their clothes baked some good might have been achieved, to counterbalance in some measure the undoubted evils entailed by the system of quarantine. It is, however, more urgent to look after the dwellings these people inhabit when they reach Marseilles than to detain them for a day or two at the islands of Frioule. Unfortunately the condition of the poorer quarters of Marseilles remains the same now as before and during the recent cholera epidemics. It seems especially absurd to hear of 28,000 persons being put in quarantine before they enter Marseilles. If any quarantine were justifiable at all, it is far more necessary to take this precaution with those who leave than with those who are about to enter a town where almost every form of epidemic disease is rife.

THE PRINCESS OF WALES AT THE BROMPTON HOSPITAL.

THE Princess of Wales, ever ready to do a gracious act, at any personal trouble, for the relief of suffering or the pleasure and comfort of the distressed, gave a concert to the inmates of the Brompton Hospital on Friday week, at which Her Royal Highness and her daughters assisted. The performance was followed by visits to the wards, during which the patients who were unable to assemble in the concert-room were spoken to and received gifts of flowers. Such actions as these are not only of great service in themselves, but they endear the Princess to the people, and strengthen that loyalty which, in spite of all, wells up in the heart of all *English* people to the Throne.

TESTS FOR VISION AMONGST RAILWAY SERVANTS.

THE question of the tests that are and should be employed to test the vision of railway servants has been the subject of discussion at a recent meeting of the engine-drivers and firemen of the Gateshead section of the North-Eastern Railway. It was acknowledged by the chairman, an engine-driver, that it was essential that railway men should have good sight, but he thought (and several of the speakers agreed with him) that the tests they were put through at present were too severe, and altogether foreign to a railway man's duties. The principal objection seemed to be raised against the use of the dots, and it appears that at a recent examination, out of 1000 men twelve or more were stopped; and, although they had not been turned adrift, they had been placed on wages which had been reduced to the extent of from five to twenty-five shillings per week. One of the speakers, whose wages had been thus reduced, had only one eye perfect, the other being defective. The whole case lies in a nutshell. The lives of the passengers must not, on any consideration, be exposed to unnecessary risk, and undoubtedly to place a train under the care of a one-eyed man is an unnecessary risk. Suppose a spark, or even a fragment of coal-dust lodged on the eye: pain, spasm, and free lacrymation would at once deprive him of all useful vision. The company are therefore perfectly right in replacing a one-eyed man, or a man with defective vision, by one

Digitized by Google

who has two good eyes, especially in an express train, when quickness as well as keenness of sight are required. But the men have, we think, just grounds of complaint that they should have been placed in positions of trust, and advanced from one post to another, and then, when they have done all the drudgery and have secured a good salary, they should be abruptly told that they are unfit for their work. It is the duty of the company and of its officers to see that no man with defective vision is entered upon its staff, but, once admitted, if his sight is found to fail, he should be pensioned, or supplied with work in which the failure of vision is of relatively small importance. He should not be allowed to be a loser for a piece of carelessness on the part of his employers.

RECRUITING FOR THE ARMY IN 1886.

FROM the annual report of the Inspector-General of Recruiting for the year 1886, we learn that the number of recruits who joined the service was 39,409, of whom 14,288 were furnished by the Militia, and that only 1688 enlisted for long service. The returns showing the numbers who offered themselves but were rejected on medical examination have not yet been completed. The reports by general officers commanding at home and abroad as to the general appearance and condition of the recruits who joined are very favourable. "In several cases the men are stated to be young, but it is rarely found that any complaint is made of the size and physique of the old soldiers of any regiment, from which it may be inferred that recruits develop in a short time into well-grown men." No information is given in the report as to the ages of the men enlisted. From a table in the appendix we find that in an average effective strength of 195,905 men serving in the army during the year there were 2721 deaths and 2789 discharges by invaliding, being in the ratio of 13·89 and 14·24 per 1000. The latter is considerably below the usual average. Of the invalided, 327 were in the first year of their service, the proportion to the number of recruits who joined amounting to 8·34 per 1000. There were 39,330 recruits raised for the Militia during the year, of whom 29,617 were for the English, 3775 for the Scotch, and 5938 for the Irish Militia; as in the case of the army, no information is given as to the numbers rejected on medical grounds, or as to the ages of the men enlisted. In a strength of 108,196 there were 447 deaths reported, or in the ratio of 4·14 per 1000. This is nearly 1 per 1000 lower than among troops of the line serving in the United Kingdom, but possibly the difference may be due to some of the deaths of Militia men not being reported. We observe that the Inspector-General compares the death-rate of the Militia with that of the army generally, instead of the troops serving at home, which is obviously a mistake.

LEPROSY IN TRINIDAD.

IN his report for the year 1885, Dr. Beaven Rake, the medical superintendent of the Leper Asylum, gives evidence of the valuable work with which we have already been made acquainted by former reports and by his communications on leprosy at Brighton in 1886. In discussing the prevalence of the phases of the disease, Dr. Rake states that in Norway the percentage of tuberculated cases is roughly double, and the percentage of anæsthetic cases is about half that in Demerara, whilst Trinidad occupies an intermediate position. In India the tuberculated form seems to sink to a minimum, and the anæsthetic form to rise to a corresponding maximum. The percentage of the mixed form would appear to undergo little change in any climate. The pathological part of the report has already been made known, but we may draw attention to the statement that seventeen observations on material taken from vaccine vesicles and pustules in lepers failed to show bacilli in any part of them. In his inoculation experiments he used dogs, cats, kittens, guinea-pigs, mice, bats, fowls, and a small insessorial bird, and his methods were by scarification of the skin and application of material scraped from leprous ulcers, by the introduction of portions of leprous tubercles beneath the skin, by the vaccination with lymph taken from lepers, and by feeding animals on tubercles, enlarged glands and viscera obtained post mortem. All the experiments were equally ineffectual, and not even a localised growth was observed. Dr. Rake speaks favourably of the healing capacity of leper tissues in surgical operations, and illustrates by photographs the local palliative treatment by excision of tubercle.

CONSULTING FEES FOR GENERAL PRACTITIONERS.

THAT plentiful individual "A Sufferer" has been again airing his grievances, and complains that medical men—general practitioners—charge a special fee when they meet a consultant or a specialist in consultation; also that they do not, like other people, send in particulars of accounts. As to the latter point, medical men are always ready to produce particulars when asked for. They probably suffer, rather than otherwise, from not giving particulars; for the most reasonable patients soon forget the particulars of medical service, and would be rather surprised at the end of the year to see how many visits and how much care they had received from their medical adviser. "A Sufferer's" complaint that his doctor, when a party, and a very important party, to a consultation, should charge an extra fee, is as ungenerous as it is unreasonable. The fee is only claimed as a rule in the case of patients who can pay it; but in itself it is most reasonable. The general practitioner's time is taken up, often to his great inconvenience and that of his other patients. His knowledge of the patient and of the case is most valuable, as every good consultant will admit. The consultation is essentially a joint business, and both parties to it should be paid—not necessarily equally, of course. We cannot think that "A Sufferer's" complaints will be very extensively shared by patients, who know how "special" is the knowledge of the general practitioner who may have watched their case over a number of years in all its relations, and whose time is often as precious as that of the consultant who is called in.

THE REGULATION OF THEATRES.

THE Bill which has been brought into the House of Commons by Mr. Dixon Hartland proposes to place all metropolitan theatres and music halls under the control of the Home Secretary, who will be empowered to grant a licence after he has been satisfied by inspectors, appointed for the purpose, as to the stability of the building, the security against fire, and the sufficiency of means of egress, &c. The Home Secretary is also to have power to frame from time to time such regulations as he may deem necessary for the establishment of decency and order. We do not gather from the Bill to what extent the authority of the Home Secretary is to supersede that of the other authorities which hitherto have controlled our places of public amusement. It will be impossible to supersede entirely the power of the Metropolitan Board of Works, which must continue to exercise some degree of control over the structure—at least, in its external relations. Again, we conclude that the Lord Chamberlain will still be able to exercise his veto on the plays to be performed in theatres, and the magistrates to exercise their power of giving or withholding licences for music and refreshments, according to the caprice of the hour. The first thing necessary in the interests of the public is that the caterers for public amusement should not be unduly harassed; and if this Bill is to

Digitized by Google

ecome law, we trust that the Home Secretary may become the ole authority for the control of theatres and music-halls, with ower to grant licences of every kind. A very important omis- ion in the Bill is the want of regulations for the provision f sufficient cubic space and ventilation. This is, from our oint of view, a very grave omission, and we trust that the Bill will not be allowed to become law unless this omission s rectified. If the Home Secretary is to protect the public gainst fire, why should he not equally protect them against uffocation? There ought to be in every theatre and music- all an observance of due proportion between the accom- nodation provided and the amount of area and cubic space. The area of the inlets and outlets for air ought also to be egulated, and the admission of a greater number of spec- ators than that for which the building is licensed should e a punishable offence. The amount of slow poisoning hat goes on in over-crowded places of entertainment is enormous, and if the State is going to step in for the pro- tection of the public, it ought to afford them at least as much protection as it affords to prisoners. We are not very strong advocates of grandmotherly legislation, but if we are to have it, by all means let it be far-reaching and effec- tual. Put the theatres under the control of one responsible Minister, but let this Minister be in turn responsible to the public for their comfort in every respect.

TYPHUS AND OVERCROWDING.

DR. RUSSELL, the medical officer of health of Glasgow, has presented to his authority a report giving an interesting account of the behaviour of typhus in an overcrowded house. This house consists of three rooms, and is situated at the end of a new street close to open fields. The stair is well lighted and airy, and the inmates cleanly and apparently respectable Scotch people. Altogether sixteen people lived there, but two of these being children, they may, for the purpose of estimating cubic space, be regarded as equal to one adult. On this assumption there were for each of the fifteen adults an average of only 199 cubic feet of air space: in the kitchen, for each of three adults, there were 188 cubic feet; in the parlour, for each of seven adults, 180 cubic feet; and in the third room, for each of five adults, 116 cubic feet. Typhus fever attacked two in the kitchen, three in the parlour, and four in the third room. How the disease was introduced is un- known, but, as Dr. Russell said, "a household living under these physical circumstances is like a barrel of gunpowder: only a spark is required—a chance contact with any wander- ing source of infection." The story is instructive, for it shows very definitely the relation between overcrowding and typhus fever, and that nothing but the watchfulness of local authorities and their officers will prevent the develop- ment of a fatal disease. In the present case the sick were removed to hospital and the rest of the household to the House of Reception, thus limiting a further spread of the malady.

VEGETARIAN v. MIXED DIET.

IT is more than doubtful whether the principle of vegetarianism will ever constitute the prevailing rule of diet. A variety of arguments have certainly been urged in its support, and the names of some who advocate its adoption are by no means undistinguished. While, how- ever, we are quite willing to acknowledge whatever merit can justly be claimed for this system, we cannot see that it has any claim to recognition as a practice well suited to the various requirements of mankind in regard to food. That subsistence and a fair degree of nutrition are compatible with the exclusive use of vegetables we do not deny. Nay, we regard it as indisputable that some constitutional con- ditions agree better with a sparing use of animal food, or even with a diet from which it is quite excluded, than if they were treated to an ordinary mixed diet. To this class we may allot the great majority of young children, though for such we should rather advise a very limited allowance of meat than its total substitution by vegetables. After all has been said that can be said, however, in favour of vegetarianism, we have no hesitation in expressing our own conviction that the great mass of adult and adolescent men and women do, and can, best nourish themselves by choosing much of the proteid and fatty ingredients of their food from the animal world.

PICTURES OF HORRORS.

THE painter must be strangely in want of average resource in the imaginative part of his intellect, or have execrable taste, who reproduces the scene of the operating theatre or the clinical lecture-room on his canvas for the public gratification. Rather let us regret that artists are beginning to pander to a depraved appetite for horrors, than assume that they are unable to provide more rational food for the eye and mind than some of the subjects said to be chosen for exhibition at the Paris Salon. It is a strange thing that anyone can endure to gloat over the scenes which the members of our profession are compelled, though most unwillingly, to witness in the performance of their duties. It is with the sole aim of relieving pain and curing disease we encounter misery. No man with a heart in his breast would see and hear what is forced upon us if he could avoid it. If at times it may seem that familiarity with suffering has rendered us callous to it, that is only a sur- face and deceptive appearance. Not unfrequently the effort to overcome the feeling of loathing excited is overdone, and medical men, especially young students, assume an air of indifference which ill bespeaks the real feelings with which they regard the scene around them. To make pictures of such scenes is unmanly, and if it do not evince a debased passion, it must be expressive of an insensate mind.

EFFECTS OF THE SUSPENSION OF THE CONTAGIOUS DISEASES ACTS.

SEVERAL of the Woolwich clergy and other influential persons are fully alive to the evils of the repeal of the Contagious Diseases Acts regulations, and the matter has again been discussed by the Board of Guardians, at a late meeting, at which the Rev. J. Jordan moved, "That this Board is of opinion that the suspension of the Contagious Diseases Act has a most injurious moral effect on the town of Woolwich. The number of soldiers in hospital suffering from contagious diseases is increased, prostitution is now more shameless than ever, and a larger number of young girls are now found on the streets." He said he came to Woolwich some years ago believing the Acts were undesir- able; he now, as the clergyman of one of the worst districts in the metropolis, was prepared to give evidence on oath if required, before any commission, that not only was prosti- tution more flagrant than while the Acts were in force, but that the number of juvenile prostitutes and bad houses had greatly increased. The rev. gentleman then detailed two cases of aggravated disease that had been brought under his notice, and which were now in their infirmary. On the motion being seconded, some discussion followed in which various views were expressed. The Rev. J. Jordan remarked that the suspension was in a great measure brought about by ladies who, though prompted by the highest and holiest motives, acted in entire ignorance of facts which happily did not, and should not, come under their notice. The motion was ultimately carried by eight to three, though it is right to say that little more than half the members were present.

TRAINING.

THE victory of Cambridge this year in the boat race has given rise to many comments as to the mode of training best adapted to get crews into condition. It has been stated that Mr. Bristowe, the President of the Cambridge University Boat Race, allowed fish, entrées, puddings, and dessert for dinner through the whole course of training, and did not insist upon the monotonous and excessive flesh diet usually enforced. For some years past there has been a growing tendency to adopt a more rational plan of feeding, and to permit a greater range of carbohydrates and hydrocarbons in the diet. Indeed, the more varied the food the better the health of the individual, and as training was defined by Professor Parkes as a method of obtaining the highest degrees of vitality, a scientific mixture of the various principles of diet is called for. With hard muscular work at a quick pace more animal food is necessary than for ordinary work, but this should never be given in excess, and beyond what the digestive secretions are able to dispose of; one pound and a half is certainly as much as is required. In giving carbohydrates, care should be taken that they are well cooked and are of a digestible character. Rice, sago, and tapioca puddings are excellent; but potatoes should not be indulged in, in any quantity, as they are apt to cause flatulence—that bugbear of the trainer known as "inwardful." The hydrocarbons should be supplied by a liberal allowance of butter; the men should be encouraged to eat the natural fat on the chops and steaks, and not cut it off, as they have been directed to do; whilst meat with plenty of fat on it is usually more tender than lean. Fresh fruits should also form part of the daily dietary, since these supply the alkaline salts so useful in keeping the blood in a healthy state. The chief article to be avoided in training is sugar, especially sugar with pastry; it tends to cause acidity and promotes "biliousness." The question among trainers is the amount of fluid permitted. Under the old system great cruelty was often practised by keeping men, especially during hot weather, on a strict allowance; this was a mistake. On the other hand, men should not be allowed too much freedom in this respect for fear of diluting the digestive fluids; it is well, therefore, to keep this within physiological limits. A man of 12 st., under ordinary circumstances, eliminates about three pints and a half from the body daily by the skin, lungs, and kidneys; with strong and quick work, he probably gets rid of one pint and a half more. Five pints of fluid would therefore be sufficient for most men. As training advanced and the elimination became less, the quantity might gradually be reduced. At the beginning of training slight excess of the physiological requirements might be permitted, as it would help tissue metabolism and carry off the waste products formed in consequence of increased muscular activity.

THE BAHAMA ISLANDS AS A HEALTH-RESORT.

Mr. L. D. POWLES, Circuit Justice at Nassau, New Providence, the capital of the Bahama Islands, draws our attention to the climatic advantages of that city, which has long been a favourite winter resort of American and Canadian visitors, and is as well known on the other side of the Atlantic as the Riviera is in England. In New Providence frost is unknown, but from November to May the heat can never be said to be excessive; bathing in the sea may be enjoyed all the year round; the vegetation of the island is luxurious, roses and other familiar flowers blooming throughout the year, and English vegetables being always on sale; and Mr. Powles concludes by expressing the opinion that to the wealthy invalid or pleasure-seeker a winter visit to Nassau must needs prove very pleasurable. As the recent calamity in the Riviera may turn the thoughts of many towards other resorts where the inclemency of an English winter can be avoided, the moment seems opportune to draw attention to a corner of Her Majesty's dominions which is as yet but little known in England, and we have consequently with pleasure given publicity to the substance of Mr. Powles' communication.

LIFE ASSURANCE IN 1886.

THE volume of Life Assurance Companies' accounts which is annually published by the Board of Trade, has made its appearance earlier this year than is usual, and contains some highly interesting figures. Thus the "ordinary" British companies, numbering ninety-three, reported between them an aggregate income of £19,679,657. The Industrial Companies, which transact a smaller class of business, received £3,706,660; so that altogether we thriftless English folk imposed upon ourselves a voluntary tax of over twenty-three million pounds in connexion with this one branch of thrift. This sum exceeds the ordinary army estimates by an amount equal to the total cost of one of our little wars. The parallel is perhaps a little fanciful—at least it is striking, and a curious circumstance that in the ordinary course of affairs we expend equal sums of money in arming ourselves against external foes and in providing against the ravages committed by that subtle adversary to whom every man must some day succumb. A comparison which the return comprises shows that 1886 was in life assurance circles a year of considerable development and growth. The total premiums collected exceeded by a full half-million sterling those of 1885; while the aggregate of invested funds was augmented by upwards of three million pounds. All this is highly satisfactory, as also is the circumstance that variations in the value of investments are shown to have yielded a net revenue to the companies of nearly £130,000. This last figure is of interest rather as indicating general prosperity than as having any special significance where it stands. As a component part of the twenty-three millions, it is a "mere drop in the bucket," but as indicating the spontaneous enhancement of value in a body of carefully selected securities it is a "straw" showing, as we hope, "which way the wind is blowing."

OXALIC ACID POISONING.

AN inquest was held by Dr. Danford Thomas at Providence Hall, Edgware-road, on the 16th ult., touching the death of Caroline Beale, aged forty-five years. Deceased had been despondent of late, and precautions had been taken to protect her life. She had suffered from hemiplegia, which rapidly improved under iodide of potassium. On March 12th she was seen to be in her usual health at 3 P.M., and at 4.30 P.M. she was found attacked with profuse diarrhœa and vomiting, death occurring shortly afterwards. At the post-mortem examination a gumma of the dura mater, as large as a hazel-nut, was found pressing on the middle of the left ascending parietal convolution. The inner table of the skull at the corresponding part was elevated in the form of a node. The brain was exceedingly congested, and there was a large amount of fluid in the ventricles and beneath the arachnoid. The back of the tongue, soft palate, and pharynx had a wash-leather-like appearance. The mucous membrane of the gullet was shrivelled, of a dirty yellowish-white colour, and corrugated both longitudinally and transversely, especially in the lower half. It could be detached with ease from the muscular coat. The stomach contained about half a pint of greenish-black tenacious material—a mixture of mucus, bile, and altered blood. The lining membrane of the stomach was generally of an injected colour, which threw into bold relief numberless spots and splashes of black, the result of hæmorrhage into and beneath

Digitized by Google

ıe mucous layer. For two inches at the pyloric end there 'as marked corrosion, the surface looking deep grey and oughy. The whole of the small and large intestine was ıflamed, and contained viscid mucus. The appearance of ıe mucous membrane was as if the latter had been washed ver with calamine lotion. The valvulæ conniventes were wollen and roughened. The contents of the stomach and he vomit were intensely acid, whilst they, together with ome liquid found in a cup, yielded a large quantity of xalic acid. From the above facts it is clear that the dose aken must have been very large, probably not less than an unce of the acid. It was not ascertained where deceased ob-ained the poison. The fatal period could not be determined, ut it could not have been much more than an hour and a half. 'he jury returned a verdict of "Suicide whilst of unsound nind." Suicidal poisoning by oxalic acid is not uncommon. 'he majority of cases are fatal, and the almost certainty of his, together with the ease with which the acid or its otash salt can be purchased, accounts for the would-be uicide resorting to such painful means of self-effacement.

THE SANITARY SERVICE.

We learn with much satisfaction that the Hendon Rural Sanitary Authority have reappointed for life Dr. C. E. Saunders, medical officer of health for that district. Dr. Saunders has faithfully performed the duties of his office in his district for fourteen years, and the authority have shown a proper appreciation of the value of his services by the course they have adopted. A member of the board, who supported the resolution, pointed out that it was unfair to leave the medical officer in such a position that it would be open to the caprice of any member to snatch a resolution which would terminate his connexion with them at any moment, and the chief opponent of the proposal acknowledged the valuable services Dr. Saunders had rendered, and admitted that the board would never regret the step they had taken. We trust that the Local Government Board will not hesitate to confirm this decision; a refusal would undoubtedly place the public health service in an unfavourable light before the profession.

CHOLERA IN AUSTRIA-HUNGARY.

We have all along feared that cholera might make its reappearance this year in Austria-Hungary, and, as we have already announced, the disease manifested itself a short time since at Esseg, in Southern Hungary. The latest news is still more disquieting, for we learn that three cases, certified to be genuine Asiatic cholera, occurred between the 25th and 29th of March at Buda-Pesth. It is not clear on which side of the river this occurrence took place; but in Pesth, on the eastern bank, where the disease was so prevalent last autumn, the conditions are specially favourable to a recurrence of the outbreak.

INDUSTRIAL DWELLINGS.

On Wednesday the Duke of Westminster opened the first of nine blocks of artisans' dwellings to be erected by the Improved Industrial Dwellings Company on that part of his estate near Grosvenor-square. This block is situated in Lumley-street, and contains accommodation for forty-six families; each holding has two, three, or four rooms, with or without a scullery; the rooms are well-proportioned and open on to well-ventilated staircases freely exposed to the external air. There is also in connexion with each holding a watercloset, and ample accommodation is provided for the storage of food and fuel. The block is substantially built, and is designed so as to enable all parts to be exposed to a free current of air; and it does not, therefore, share the objections which can be made to many so-called model lodging-houses in London. It will doubtless be a great boon to the working population in the west-end of London.

HOSPITALS AND THE JUBILEE.

Mr. Henry C. Burdett writes a long letter to *The Times* supporting the claims of the metropolitan hospitals on the Jubilee year. He thinks £500,000 might be so raised, provided the Queen and the Royal Family were identified with the movement. There is no doubt that this is the most favoured notion of the shape which the Jubilee fund should take. But there is no time to be lost. Every week which elapses without form and impulse being given to the movement is a week lost.

DORCHESTER TOWN COUNCIL AND THE SMALL-POX EPIDEMIC.

It is alleged that the Dorchester Town Council have refused to pay medical men who have sent cases to the Small-pox Hospital and treated them there, after being assured by the medical officer of health that they would be remunerated for so doing. It is said that the services of the medical men in stamping out the epidemic were very valuable. We cannot believe that the Town Council will disavow its obligation for such services, especially when bespoken by their own medical officer of health.

THE ANILINE TREATMENT OF PHTHISIS.

Dr. Kremianski's idea of curing tuberculosis by converting the blood into a dilute solution of aniline (see The Lancet, March 5th) has been tried by Dr. Nesteroff on a patient who was about to be sent to the south, with the result that he became rapidly worse and died in a fortnight. The Moscow Medical Society, before whom the matter was brought, were nearly unanimous in the opinion that the aniline treatment would be not merely useless, but positively dangerous.

THE MARGARET-STREET INFIRMARY.

We have been requested to publish the following resolution, passed unanimously by the Council of the Metropolitan Counties Branch of the British Medical Association, at a meeting held on March 25th: "This Council fully approves the conjoint action taken by Dr. Thomas Hawkesley, Dr. W. Cholmeley, Mr. Carr Beard, Dr. Featherstone Phibbs, Dr. Julian Willis, Dr. Robert Walford, and Dr. Scudamore Powell, in resigning their appointments at the Margaret-street Infirmary; and trusts that their action will strongly recommend itself to the approval of members of the profession generally."

DEATHS OF EMINENT FOREIGN MEDICAL AND SCIENTIFIC MEN.

The deaths of the following foreign medical and scientific men are announced:—Dr. Don Cayetano Pichardo y Estrada, of Puerto Principe in Cuba, Military Surgeon and Professor of Mathematics in the Institute of Puerto Principe. Dr. Don M. Orozco, of Irepueto, Mexico.

THE CHARGES AGAINST MERCER'S HOSPITAL.

It will be remembered that some short time ago a charge of brutal treatment of a patient was made against Mr. Kennedy, the resident medical officer at Mercer's Hospital, Dublin. The matter was thoroughly sifted by a committee, and subsequently the charge of assaulting the patient was brought before a jury. By both of these tribunals Mr. Kennedy was acquitted, the evidence in his favour being ample to

Digitized by Google

impress any impartial person with the injustice of the charge. It has now been decided to present him with an address expressive of sympathy with him in the ordeal through which he has been compelled to pass, and a testimonial to enable him to meet the heavy legal expenses to which he has been put. The hon. treasurer, to whom subscriptions for this object may be sent, is Dr. M'Veagh, 1, Rutland-square East, Dublin.

MULTIPLICATION OF SPECIAL HOSPITALS.

WE hear of the establishment of "The London Hospital for Diseases of the Throat, Nose, and Ear," which sounds very like the title of other similar institutions. We regret the multiplication of special hospitals, and advise the public to favour the great general hospitals, which have special departments.

FOREIGN UNIVERSITY INTELLIGENCE.

Erlangen.—Dr. Frommel of Munich has been elected to the Professorship of Midwifery.

Groningen.—Dr. Korteweg, chief of the Jewish Hospital, has been appointed Professor of Surgery, vice Professor Ranke, deceased.

Leipsic.—Dr. Wiedemann has been appointed Professor of Physics and Director of the Physical Institute.

Prague.—Professor Soyka has obtained accommodation for a Hygienic Institute, which he hopes to be able to open at the commencement of the summer session.

SURGEON-GENERAL WILLIAM RUTHERFORD, C.B., hon. physician to the Queen, whose death recently occurred at the age of seventy-one, entered the army as assistant-surgeon in 1841, became surgeon in 1852, deputy surgeon-general in 1861, and surgeon-general in 1874. Dr. Rutherford served in the Sutlej campaign of 1845-56 and in the Eastern campaign of 1854-55, including the siege of Sebastopol, and for his services received the medal with clasp and the Turkish medal. In 1857 he proceeded to China on the staff of the Lieutenant-General commanding the expeditionary force, and in 1859 was appointed sanitary officer to the army serving in China. In 1860 he served during the campaign in the North, for which he received the medal and two clasps. In recognition of his distinguished services, he was made a Companion of the Order of the Bath in 1867, and retired from the service in 1876. He was appointed an honorary physician to the Queen in 1880.

A MEETING of the delegates of the two Royal Colleges was held on Tuesday last to consider the terms of the Charter about to be submitted to the Crown, and it was determined to recommend the Colleges to apply for a purely medical degree, and not to combine with King's and University Colleges as constituent parts of a complete teaching University.

AMONGST the elections made in connexion with the forthcoming International Medical Congress are the following:—Dr. Robert Barnes as a vice-president of the Gynæcological Section; Dr. Edis as a vice-president of the Section of Obstetrics; Professor Hirschberg as a vice-president of the Ophthalmological Section.

THE American State of Maine has, during the past month, reverted to its former system of punishing murderers with life imprisonment instead of the gallows.

SIR W. B. FOSTER has been elected Member of Parliament for the Mid or Eastern Division of Derbyshire.

THE Right Hon. Arthur James Balfour, M.P., by a Warrant under Her Majesty's Royal Sign Manual, dated Feb. 3rd, has been appointed to fill the vacancy on the Senate of the University of London occasioned by the death of George Busk, Esq.

AT a recent meeting of the Council of the Lancashire and Cheshire branch of the British Medical Association it was resolved that a testimonial be raised to Dr. Edward Waters in recognition of his earnest devotion, through many years of self-sacrifice, to the cause of medical reform.

EIGHT directors of the Perth Infirmary have resigned in consequence of the strained relations between the Board of Directors and the medical officers of the institution, especially with regard to their failing to re-elect Dr. Bramwell to the position of senior visiting medical officer.

ON the 24th ult. the death occurred, on board the steamship *Lusitania*, in the Mediterranean, of Viscountess Strangford, who was on her way to Port Said for the purpose of organising and opening the new Hospital for British Seamen which is being erected there by subscription.

A SCHEME has been prepared with the object of founding a National Pension Fund for hospital officials and trained nurses. A register for the names of those desirous of joining the fund has been opened at the offices of the Hospitals Association, Norfolk-street, Strand, W.C.

DR. ALFRED MEADOWS has been elected an Honorary Member of the Obstetrical Society of Philadelphia.

THE ROYAL NAVAL HOSPITAL, HASLAR.

As we announced last week, the course of instruction at the Royal Naval Hospital, Haslar, for the eighteen surgeons who entered the Navy in February last, was opened on March 10th by Sir John Watt Reid, K.C.B., the Director-General of the Medical Department of the Navy, in the presence of the Commander-in-Chief and staff, and other officers.

In a brief speech, the Director-General welcomed the young officers to the Service and the hospital. He warmly congratulated them on the exceptionally high marks which had been obtained by them in the competition at Burlington House, and exhorted them to strive to maintain throughout their service career the high figure of merit with which they commenced it.

The introductory address was then delivered by Fleet Surgeon Walter Reid. He alluded to the presence of the Commander-in-Chief and other officers as a testimony to the fact that the executive or governing branch of the service is always ready to extend the hand of welcome to capable medical gentlemen who have elected to join the Royal Navy. The officers were again congratulated upon the excellent positions they had taken in the competitive examinations, and satisfaction was expressed that the service was becoming more popular in the medical schools, and that its solid advantages, together with its other attractions, were better known and more highly appreciated as a means of livelihood and a field of labour for medical men than they were some years ago. The officers were then advised to make themselves acquainted with the nature and character of the service which they had entered, to know its purposes and its duties to the State, and thus to arrive at a right conception of the responsibilities they had accepted by enlisting in its ranks. After explaining the course of study which lay before them, Dr. Reid concluded his lecture with some words of advice to the young officers. He enjoined them to cultivate a proper sense of duty, and to look to it for a rule of conduct and a

Digitized by Google

guide in all they had to do in the service of the Navy. It was their duty to be loyal to the Sovereign who was the head of the Navy, and in whose name all their services were performed. They were to obey their superior officers, and to extend to them the marks of respect to which their rank and position entitled them. It was their duty, by regular study and attention to opportunities for instruction and experience, to try to perfect themselves in the science and art of their profession, so that whensoever or whereseever required they might be prepared to bring its blessings to the side of their fellow-men. They were warned against unfitting themselves for the proper exercise of that profession by habits of selfish or vicious indulgence. They were enjoined to remember that they now represented two great professions, than which none could well be nobler or more worthy to be held in honour. They were naval officers as well as medical gentlemen. It was their duty, by all means in their power, to endeavour to represent both these positions worthily. By doing so they would follow the course which was best for the public good and also for their own, and one which would give them every right and every reason to expect a happy and a prosperous future as medical officers of the Royal Navy.

WILLS OF MEDICAL MEN.

THE Scotch Confirmation under seal of office of the Commissariot of the county of Edinburgh, of the trust disposition and settlement and holograph codicil of Dr. James Dunsmure, of 53, Queen-street, Edinburgh, who died on October 16th last, granted to Dr. James Dunsmure, the son, the accepting executor nominate, was resealed in London on the 3rd ult., the value of the personal estate in England and Scotland amounting to upwards of £49,000.

The will of James Surrage, M.D., late of 2, Saville-place, Clifton, Bristol, who died on November 19th last, was proved on the 17th ult., by the Rev. Thomas Stevens and Mr. Noblett Surrage Ruddock, the nephew, the executors, the value of the personal estate amounting to over £39,000. The testator bequeaths legacies to his sisters, brothers, brother-in-law, and executors. The residue of his real and personal estate he leaves upon trust for his wife for life, and then for his children or issue as she shall appoint.

The will of William Bell, M.D., formerly of 16, Hertford-street, Mayfair, and late of Merlin, Eastbourne, who died on December 14th last, was proved on the 3rd ult. by Mr. Richard Ebenezer Shackleton, the nephew, the sole executor, the value of the personal estate amounting to over £19,000. The testator, after stating that his wife Mrs. Margaret Bell is already fully provided for, bequeaths to her his wines, jewellery, and horses; three pictures to his son William Abraham; his furniture, plate, and the remainder of his effects to his wife for life; and his property, Longstone Hall, Longstone-road, Eastbourne, to his daughters Esther and Susan. The residue of his property he leaves upon trust for his said daughters; and on the death of the survivor of them for his said son for life and then for his children.

The will of Mr. George Leigh, M.R.C.S., late of Arnold, Notts, who died on July 26th last, has been proved at the Nottingham District Registry by the Rev. Hugh Bryan, the sole executor, the value of the personal estate exceeding £3000. Subject to bequests to Sarah Henrietta Badnall, the testator leaves all his property upon trust for the children of the said Hugh Bryan and his (testator's) daughter Mary Emilie Leigh Bryan.

The will of Duncan Matheson, M.D., late of 4, Granville-place, Portman-square, who died on February 5th last, was proved on the 9th inst. by Mrs. Agnes Matheson, the widow, one of the executors, the value of the personal estate exceeding £3400. The testator gives the whole of his property, real and personal, to his wife for her absolute use and benefit, subject to her maintaining and educating his children during their minority.

The will of Alfred Wiltshire, M.D., late of 57, Wimpole-street, Cavendish-square, and of Torridon, Somers-road, Reigate, who died on December 4th last, at Virginia Water, was proved on the 16th inst. by Mrs. Kate Wiltshire, the widow and sole executrix. The testator gives all his property, both real and personal, to his wife absolutely.

The following legacies have recently been left to hospitals and other medical institutions:—Mr. George William Pierrepoint Bentinck, J.P., late of Terrington, Norfolk, £1000 each to King's College Hospital, St. Mary's Hospital, Paddington, Charing-cross Hospital, St. George's Hospital, Hyde-park corner, the Great Northern Hospital, University College Hospital, the Hospital for Sick Children, Great Ormond-street, the London Hospital at the East-end, and the London Homœopathic Hospital, Great Ormond-street.—Mrs. Susannah Beloe, late of Queen-street, Gravesend, £250 each to the National Hospital for the Paralysed and Epileptic, Queen-square, Bloomsbury, the Gravesend Hospital, the Hospital for Consumption and Diseases of the Chest, Fulham-road, and the Cancer Hospital, Fulham-road.—Mrs. Charlotte Elizabeth Thomasina Holmes, late of 7, Holland-villas-road, Kensington, £1000 each to the North London or University College Hospital, the Great Northern Hospital, Caledonian-road, Islington, the London Hospital, Whitechapel-road, King's College Hospital, Portugal-street, Lincoln's-inn-fields; £500 each to the Hospital for Consumption and Diseases of the Chest, Brompton, the Royal Hospital for Incurables, West-hill, Putney-heath, and West London Hospital.—Mr. George Hawkins, late of 28, City-road, £500 to the London Hospital, Whitechapel; £100 each to the Royal Hospital for Incurables, Putney-heath, Victoria-park Hospital for Diseases of the Chest; and £50 each to the London Dispensary, Spitalfields, the City of London Truss Society, and the Royal London Ophthalmic Hospital.—Mrs. Elizabeth Salisbury Heywood, late of Summerfield, Bawdon, Cheshire, £200 to St. Mary's Hospital and Dispensary, Quay-street, Manchester.—Mr. Alfred Bishop, late of Severn Villa, Highbury New Park, £500 to the London Hospital, Whitechapel-road; £100 each to the London Dispensary, Church-street, Spitalfields, and the Poplar Hospital.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Stroud Urban District.—On a population of 9473, the birth and death rates were 29·9 and 16·8 per 1000 respectively; the rate under one year being 133 per cent. of registered births. Eleven cases of small-pox came under Mr. Partridge's notice, and owing to the absence of means of disinfection, some comparatively valuable articles of clothing &c. were destroyed, compensation being given in one case. Apparently also there is no infectious hospital, for we read that as a precaution a cordon was drawn round the houses. This is a risky expedient, for English law only allows of the isolation of the sick and not the healthy, and all but the actual sick can at any time decline to submit to cordons and quarantine detentions. The only confluent attacks were in the unvaccinated. The town has a good water service; the bakehouses, slaughter-houses, and common lodging-houses are duly inspected, and a substantial amount of current work is carried on.

King's Norton Rural District.—During 1886 the birth-rate was 26·69, the death-rate 13·61, and the zymotic rate 1·31 per 1000. These may be regarded as satisfactory, but the deaths of children under one year of age should not reach 18·8 per cent. of registered births. Mr. Hollinshead believes this child mortality to be materially added to by improper feeding and clothing, and to undue exposure at too early an age. No death took place from either small-pox or scarlet fever, but 40 cases of the latter came under notice. Diphtheria caused 6 deaths, and it is pointed out that the disease was associated with such local sanitary defects as offensive ash-pits, impure surface-wells, and the escape of drain air into dwellings. Speaking generally, improvement is in progress in such matters as extension of drainage works; but King's Norton is still in need of a proper system. The privies and ash-pits constitute the great nuisance in the district, and wherever nuisance is caused steps should be taken to ensure a permanent remedy. Bye-laws alone can deal with new structures. Out of 40 cases of scarlet fever adverted to, 38 were removed to the infectious hospital, which is credited with having saved the district from a severe attack. The hospital is serving an excellent purpose, but two neighbouring districts having arranged for its use, further provision for the classification of the different

Digitized by Google

diseases is needed. So far, 100 cases have been admitted, and only one fatal case has resulted.

Withington Urban District.—Dr. Railton gives the general death-rate of this district, with 21,000 inhabitants, as only 12 per 1000, the deaths under one year being as low as 9 per cent. of registered births. The zymotic rate was slightly higher than that for the past three years, but it did not exceed 1·5 per 1000. Measles was prevalent in the early part of the year, and led to school closing as a precaution. There was also some scarlet fever, 14 cases being isolated in hospital. A notification system was organised during the latter half of 1886, which is said to have led to satisfactory results, including the disinfection of 70 houses, the destruction of, with consequent compensation for, 34 beds; and the stoving, at the expense of the authority, of 35 beds. The drainage of Withington still pollutes streams, but steps are in progress for its interception. The systematic inspection of houses still progresses, and of all the notices issued in consequence in 1885, only one stood over at the end of last year. The total result of this inspection is set forth, and the plan is worthy of imitation elsewhere.

Hastings Urban District.—This borough is now estimated to contain a population of 51,224, and on this the corrected death-rate is 14·0 per 1000 living, being the lowest rate on record for ten years. Nine cases of small-pox, a residuum of the 1885 outbreak, were removed to the Sanatorium, to which a number of scarlatina cases were also taken. The borough now possesses two separate hospitals for infectious diseases, and although they may not be of the best, yet they are an invaluable safeguard. In his account of the current proceedings, Mr. Knox Shaw shows that a good deal of steady work is being carried on, which aims at the prevention of infectious disease and the improvement of the district. A sunshine recorder shows that bright sunshine is maintained on an average for more than 1720 hours in the year; and in this connexion we note that smoke consumption is looked after in the health department.

Bisley Urban District.—As in Stroud, we read here again of quarantine being observed, although there were no positive symptoms of disease. If voluntarily submitted to, well and good; but it should be remembered that such detentions are not sanctioned by law, which provides for the isolation of the sick, and the protection of the healthy by vaccination. The general work of the health department is set forth in Mr. Partridge's report, but there was nothing of especial interest during the year.

Hereford Combined District.—In Hereford city some two thousand inhabitants still draw their water from local wells, and this although a wholesome public service is available. Much is being done to improve the drainage arrangements by enforcing proper flushing cisterns to house closets and ventilation of soil-pipes. The ventilation of the public sewers by rain-pipes is properly condemned by Dr. Sandford, and, in so far as these exist, he recommends alteration in this respect. With a public abattoir the faulty slaughter-houses may, it is hoped, be got rid of. The city also needs an infectious hospital. The death-rate was 21·1 per 1000. In the Hereford rural area the rate was 14·4 per 1000, and the district is said to be maintained under constant supervision. In the Ledbury rural district the rate was 16·0, and it is stated that, apart from the need for flushing, the new sewers in Ledbury work well. Ample statistics and details as to current work are given for these and the other districts, but the area is, in one respect, fortunate in having no striking sanitary history to record for the year. Improvements are steadily going on, and no severe epidemic has prevailed.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN twenty-eight of the largest English towns 5758 births and 4155 deaths were registered during the week ending March 26th. The annual rate of mortality in these towns, which had increased in the preceding six weeks from 19·5 to 22·4, further rose last week to 23·5. During the first twelve weeks of the current quarter the death-rate in these towns averaged 22·1 per 1000, and was 2·1 below the mean rate in the corresponding periods of the ten years 1877-86. The lowest rates in these towns last week were 16·1 in Derby, 16·3 in Brighton, 20·4 in Halifax, and 20·5 in Birmingham. The rates in the other towns ranged upwards to 30·1 in Huddersfield, 33·0 in Sunderland, 34·6 in Oldham, and 35·4 in Manchester. The deaths referred to the principal zymotic diseases in the twenty-eight towns, which had increased in the preceding six weeks from 340 to 462, further rose last week to 465; they included 223 from measles, 97 from whooping-cough, 46 from scarlet fever, 35 from diarrhœa, 32 from "fever" (principally enteric), 26 from diphtheria, and 6 from small-pox. These zymotic diseases caused the lowest death-rates last week in Brighton, Birkenhead, and Bolton; and the highest rates in Huddersfield, Oldham, and Sunderland. The greatest mortality from measles occurred in Manchester, Hull, Leicester, Liverpool, Norwich, Oldham, Huddersfield, and Sunderland; from whooping-cough in Nottingham, Oldham, and Blackburn; from scarlet fever in Salford and Oldham, and from "fever" in Leicester. Of the 26 deaths from diphtheria in the twenty-eight towns, 15 occurred in London, 3 in Birmingham, and 2 in Leicester. Small-pox caused 2 deaths in Greater London, 2 in Cardiff, 1 in Portsmouth, 1 in Manchester, and 1 in Blackburn, but not one in any of the twenty-three other large provincial towns. Only 2 cases of small-pox were under treatment on Saturday last in the metropolitan hospitals receiving cases of this disease. The deaths referred to diseases of the respiratory organs in London, which had been 433 and 474 in the preceding two weeks, further rose last week to 509, but were 35 below the corrected average. The causes of 126, or 3·0 per cent., of the deaths in the twenty-eight towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Bolton, Norwich, Wolverhampton, Preston, and Halifax. The largest proportions of uncertified deaths were registered in Salford, Sheffield, Sunderland, Hull, and Cardiff.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 23·6, 25·0, and 26·2 per 1000 in the preceding three weeks, declined again to 25·9 in the week ending March 26th; this rate exceeded by 2·4 the mean rate in the same week in the twenty-eight large English towns. The rates in the Scotch towns last week ranged from 10·8 in Leith and 21·4 in Dundee, to 28·4 in Glasgow and 36·8 in Aberdeen. The 646 deaths in the eight towns last week showed a decline of 9 from the number in the previous week, and included 55 which were referred to measles, 31 to whooping-cough, 18 to scarlet fever, 14 to diarrhœa, 6 to diphtheria, 3 to "fever" (typhus, enteric, or simple), and not one to small-pox; in all, 127 deaths resulted from these principal zymotic diseases, against 98, 101, and 113 in the previous three weeks. These 127 deaths were equal to an annual rate of 5·1 per 1000, which exceeded by 2·1 the mean rate from the same diseases in the twenty-eight English towns. The fatal cases of measles, which had been 27, 43, and 50 in the preceding three weeks, further rose last week to 55, of which 23 occurred in Glasgow and 32 in Aberdeen. The 31 fatal cases of whooping-cough also exceeded the numbers in recent weeks, and included 14 in Glasgow, 7 in Edinburgh, and 4 in Aberdeen. The deaths from scarlet fever, which had been 19, 14, and 9 in the preceding three weeks, rose again last week to 18, of which 12 occurred in Edinburgh, 3 in Glasgow, and 2 in Dundee. The 14 deaths attributed to diarrhœa showed an increase upon the number in the previous week and in the corresponding week of last year; 5 were returned in Edinburgh and 4 in Glasgow. Four of the 6 deaths from diphtheria occurred in Glasgow; and the 3 deaths referred to "fever" showed a decline of 5 from the number in the previous week. The deaths referred to acute diseases of the respiratory organs in the eight towns, which had been 135 and 152 in the preceding two weeks, declined again last week to 146, and were 2 below the number in the corresponding week of last year. The causes of 84, or 13 per cent., of the deaths registered in the eight towns during the week were not certified.

HEALTH OF DUBLIN.

The rate of mortality in Dublin, which had been 28·1, 31·3, and 29·3 per 1000 in the preceding three weeks, rose again to 31·3 in the week ending March 26th. During the first twelve weeks of the current quarter the death-rate in the city averaged 30·9 per 1000, the mean rate during the same period being but 20·8 in London and 21·6 in Edinburgh. The 212 deaths in Dublin last week showed an increase of 14

Digitized by Google

pon the number in the previous week; they included 7 hich were referred to scarlet fever, 4 to measles, 4 to fever" (typhus, enteric, or simple), 3 to whooping-cough, nd not one either to small-pox, diphtheria, or diarrhœa. hus the deaths from these principal zymotic diseases, hich had been 15, 10, and 7 in the preceding three weeks, ose again last week to 18; they were equal to an annual ate of 2·7 per 1000, the rates from the same diseases being ·1 in London and 4·8 in Edinburgh. The 7 deaths from carlet fever showed a considerable increase upon the numers in the previous two weeks, and the 4 from measles xceeded the number in any previous week of this year. he 4 deaths referred to "fever" corresponded with the umber in the previous week. The deaths of infants were within one of the number in the previous week; those of lderly persons showed a marked increase upon recent weekly numbers. Two inquest cases and 2 deaths from violence were registered; and 65, or nearly a third, of the deaths occurred in public institutions. The causes of 35, or nearly 17 per cent., of the deaths registered during the week were not certified.

HEALTH STATISTICS OF CAPE TOWN.

Dr. Fisk, the sanitary officer for Cape Town, has just presented to the Town Council his report for 1886. The number of known deaths during last year in Cape Town was 1163. This, in a population of 45,000—an estimate allowing for an increase of 11,000 since the census was taken, twelve years ago—is at the rate of 25·8 per 1000 per annum. This high rate, in the absence of any severe epidemic, is 5·6 less than in the previous year, when it was 31·4. The comparatively low death-rate among the Malay population is somewhat surprising, only 265 out of the 1163 deaths which took place during the year being Malays. The Malay death-rate was 17·6 per 1000, thus raising the death-rate of the non-Malay population to about 30 per 1000, the Malay population of Cape Town being estimated at 15,000, or one-third of the total population. Against the 1163 deaths there are to be placed 1143 births. In the previous year the births were 169 fewer, and the death-rate was much higher. The mortality amongst very young children is excessive, 558 children, of whom 274 were coloured, dying in 1886. Poverty, bad hygiene, and insanitary surroundings, are of course the main causes of this infantile mortality. Dr. Fisk in his report asks for increased powers to deal with certain defects in the sanitary state of the town—powers which we trust the Town Council will confer upon him, considering that Cape Town is the place where most visitors to the colony land, and where, whether in search of health or fortune, they almost invariably remain for some time.

THE SERVICES.

Deputy Surgeon-General T. N. Hoysted has arrived in India, and been appointed to the Royal Presidency for duty. Deputy Surgeon-General J. Tulloch, M.D., has taken over the duties of Principal Medical Officer of the Woolwich District. Deputy Surgeon-General J. B. C. Reade, C.B., has been appointed Principal Medical Officer of the Home District, in succession to Sir J. A. Hanbury, K.C.B., ordered to the Mediterranean.

INDIA OFFICE.—The Queen has approved of the retirement from the Service of the undermentioned Officers:—Brigade Surgeon James Keess, M.D., of the Madras Medical Establishment (dated Jan. 4th, 1887); and Surgeon-Major Olliver Thomas Duke, of the Bengal Medical Establishment (dated Feb. 22nd, 1887). The undermentioned Officer has been granted a step of honorary rank on retirement:—Brigade Surgeon James Keess, M.D., of the Madras Medical Establishment, to be Deputy Surgeon-General (dated Jan. 4th, 1887).

ARTILLERY VOLUNTEERS.—1st Northumberland and Sunderland: Acting Surgeon W. H. Besant resigns his appointment (dated March 26th, 1887).—4th Lancashire: Acting Surgeon Edwin Hyla Greves, M.D., resigns his appointment (dated March 26th, 1887).

RIFLE VOLUNTEERS.—10th Lanarkshire (Glasgow Highland), Surgeon Thomas Buchanan is granted the honorary rank of Surgeon-Major (dated March 26th, 1887).—1st Lancashire: Surgeon J. W. Cavanagh resigns his commission; also is granted the honorary rank of Surgeon-Major, and is permitted to continue to wear the uniform of the corps on his retirement (dated March 26th, 1887).—2nd Midlothian (Midlothian and Peeblesshire): John Cameron, M.D., to be Acting Surgeon (dated March 26th, 1887).—2nd Shropshire: Acting Surgeon R. de la Poer Beresford, M.D., to be Surgeon (dated March 26th, 1887).

THE VOLUNTEER MEDICAL STAFF CORPS.—The London Division: Surgeon Eustace Agustus Burnside resigns his commission (dated Feb. 5th, 1887).

Correspondence.

"Audi alteram partem."

THE COLLEGE OF PHYSICIANS, THE COLLEGE OF SURGEONS, AND THE SOCIETY OF APOTHECARIES.

To the Editors of THE LANCET.

SIRS,—The refusal of the Colleges of Physicians and Surgeons to admit the Society of Apothecaries to a seat on the Examining Board for England has, for various reasons, been represented to the medical profession as unreasonable and likely to injure the prosperity of the profession. But when the case for the two Colleges is fairly put, it will be obvious that the demand for a combination has been urged with very slight reference to the facts and considerations which have swayed the colleges in framing their answer. The proposal for combination of the three licensing corporations in London is no new one. It has been discussed over and over again, but various difficulties have prevented its consummation, and now the altered conditions of medical education render the combination undesirable. The first proposal, made many years ago, that the two Colleges and the Society of Apothecaries should join in giving their licence was, after much discussion, set aside by a second scheme which was to include the then four English Universities with the Colleges and the Apothecaries' Society, that one portal for admission to the profession might be constructed. This scheme was discussed by a select committee of these several bodies, which met about seventy times, and settled much useful detail, but arrived at no common agreement. Then arose agitation in Parliament for legislation in medical matters, which resulted in the sitting of a Committee of the House of Commons, and later in the issue of a Royal Commission. Both took evidence, and published their reports in 1881-82. Perusal of the minutes of evidence thus obtained teaches how strongly at that time medical opinion was disposed to deprive the Society of Apothecaries altogether of their licensing power. Dr. Glover, now an elected member of the Medical Council, told a Committee of the House of Commons in 1879 that the Apothecaries' Society, though it had done good work in the past, was no longer wanted. The Royal Commissioners state also in their report that "there is a notable concurrence of opinion among the witnesses that the examinations of the Society of Apothecaries have not been satisfactory." In 1883 Mr. Gladstone's Government carried through the House of Lords the Medical Acts Amendment Bill, which, through stress of political business, failed to pass the House of Commons. On the third reading of this Bill Lord Salisbury, with the assistance of Lord Carlingford, the Lord President, and of Lord Camperdown, who had been President of the Medical Acts Commission, moved the expurgation from the Bill of the proviso that the Apothecaries' Society should continue to send a representative to the Medical Council; a deprivation which, as Lord Carlingford pointed out, would destroy the Society's power of granting licences. It was admitted by those who joined in the debate, that the claims of the Society of Apothecaries were of the slightest, and accordingly the Bill passed the Lords with the omission of the Apothecaries from representation on the Medical Council. In consequence of the various delays in the Legislature, the College of Physicians and the College of Surgeons entered into fresh negotiations for a union for examining purposes. These negotiations have established the Conjoint Examining Board for England, and its curriculum and standards of requirements in medical subjects are now familiar to teachers and students. This improvement in medical education being firmly established, there is good reason to expect that if the harmonious action

Digitized by Google

of the two Colleges be maintained others may be added, notably one pressing for immediate solution—the attainment of power to grant medical degrees to candidates who have studied in London and qualified under the conjoint scheme. This improvement would be greatly delayed, if not prevented altogether, by admission of a new body with different views and aims, like the Society of Apothecaries, to the conjoint board. Moreover, during the negotiations which took place between the two Colleges, when arranging their compact, it was never contemplated by either body to invite the Society of Apothecaries to join in the scheme, nor did that corporation, while the negotiations were in progress, ask to be allied with the Colleges. Now that the scheme is a success, the Apothecaries want a share in it. But this application, be it remarked, was also not made until the passing of the Medical Act of 1886 compelled the Society to alter its examination under penalty of losing the power of giving a registrable qualification. Now, though the application is made, there is no suggestion as into what part of the examination, under the conjoint scheme, the Society believes its intervention would be valuable. Nor does it allege that there are subjects which have been omitted from the requirements of the conjoint scheme which ought to be included. On the contrary, that scheme is complete, and the Society would not enlarge the comprehensiveness of the examination, nor raise the standard of knowledge higher than the conjoint board hold it already. The Medical Act of 1886 has provided the Apothecaries with means for giving a registrable qualification independently of any other licensing corporation, by allowing them to obtain from the Medical Council assistant examiners in Surgery; a subject which their examinations hitherto have not touched. They have made this application, and the Medical Council in February postponed complying with it until the Colleges had been again invited to consider the practicability of admitting the Society to a share of their conjoint examination. So little expectation (possibly so little desire) had the Society that the Colleges would alter their opinions, that the Society's representative on the Medical Council voted against this appeal to the Colleges. It would seem that he desired that the Society of Apothecaries should at once acquire the power to act independently. While the Medical Act of 1886 was going through Parliament the College of Surgeons refrained from any expression of opinion respecting the propriety of preserving to the Apothecaries the power to give a registrable qualification, believing that it would be unfair to deprive the Society of this power after they had exercised it for many years. Further, to have done this would have been combating the declared object of the Act—its central idea—viz., to secure that every registered qualification should depend on a complete examination in medicine, surgery, and midwifery. The Act nowhere urges the establishment of a single portal, as it is now contended in some quarters is the object of the Medical Act of 1886. On the contrary, it provides for a failure or inability to combine which was foreseen. It is clear, then, that the Colleges are not to blame for the disappointment of those who desire unification of examining and licensing powers. The Legislature, guided by the evidence taken before it and before the Royal Commission, decided to maintain the independent action of the licensing bodies. Collegiate action had no part in this decision. Then, looking at the question from the point of public advantage, the maintenance of the Apothecaries in their power to grant their licence as a registrable qualification cannot be called a scandal without throwing a slur upon the present L. S. A.'s, which they by no means deserve. Still less when it is recollected that the future holders of this licence will be qualified in surgery as well as in medicine and midwifery, which the present holders are not. In this the public would be gainers. Further, if the Apothecaries are compelled to compete with the Colleges of Physicians and Surgeons, it must be by raising their standard of education and examination; by this change the public will again be gainers. There is no reason to expect that the two Colleges will be induced to lower their standard in order to draw candidates away from the Society of Apothecaries. In spite of competition, the College of Surgeons for many years before it combined with the College of Physicians, and in conjunction with that body, has given [redacted] requirements for the diploma; [redacted] consequence of this [redacted] diplomas of the [redacted] the medical profession in England. Still more, it must not be forgotten that there is a large number of respectable medical practitioners whose powers or opportunities for study have been insufficient to enable them to pass the examinations of the two Colleges. Such men have been compelled to go to Glasgow, Edinburgh, or Dublin, where they have been able to qualify after repeated rejections in London. For such persons (by no means merely idle, careless students) the licence of the Apothecaries' Society will in future afford a means for entering the roll of practitioners and occupying a worthy position thereon. A further argument put forward by the Apothecaries for their admission to the Conjoint Examining Board is that the existence of the Society will thereby be assured, and with its assured existence the Society's power to prosecute irregular practitioners will be secured. Now, it may be remarked that this argument is put forward by those very advocates who contend that the Apothecaries would still contrive to exist even if left to act independently in granting licences, and that the two Colleges might suffer harm through its independent and competitive action. But it is very doubtful if this resolution of the two Colleges will shorten the life of the Apothecaries' Society, or that the continued career of the Apothecaries' Society will be injurious to the two Colleges. Even if the Society should become extinct as a power in medical politics, the authority to prosecute irregular practitioners could be conferred on some other body—the Medical Council, for example; it would not be allowed to drop.

I am, Sirs, yours truly,

BERKELEY HILL.

THE THEORY AND TREATMENT OF PLACENTA PRÆVIA.

To the Editors of THE LANCET.

SIRS,—I hope it will not be considered superfluous on my part if I offer a few observations upon this grave complication of pregnancy in addition to the very interesting letters of Dr. James Murphy (THE LANCET, March 12th) and Dr. Braxton Hicks (THE LANCET, March 26th). Both letters bear testimony to the command achieved by modern science over a complication long marked by disaster to mother and child. So long as the false and appalling doctrine of "*unavoidable hæmorrhage*" approved by Levret, Rigby, Denman, Cazeaux, and Gardien prevailed, which assumed that there could be no arrest of hæmorrhage until labour was completed, brutal logic compelled instant resort to the *accouchement forcé*. Thus, all opportunity of observing the ways of nature and arriving at the true theory of placenta prævia was barred. The theory of "unavoidable hæmorrhage" translated into practice meant violent delivery, by forcing the hand through the cervical canal, dilated or not dilated, seizing the child and dragging it away. The happy discovery of Dr. Braxton Hicks of the bimanual—or, as I prefer to call it, the bipolar—method of turning has rendered the violent method of delivery unnecessary and unjustifiable. As I have said ("Obstetric Medicine and Surgery"), "Braxton Hicks' bimanual operation here finds one of its most useful applications." But it is only an application. It cannot be raised to the rank of *the treatment* of placenta prævia. This practical question is not so simple. Rational treatment must be based upon true theory and correct clinical observation. Clinical observation led Puzos, Wigand, d'Outrepont, Robert Lee, Mercier, myself, and others to recognise cases in which continuous hæmorrhage did not occur, and in which nature could be trusted. Still, it was not until 1847, when I first enunciated the new theory of placenta prævia in THE LANCET, that the more intelligent and successful principles of practice fairly made way. In 1844–45 Sir James Simpson, adopting the view of Kinder Wood, Radford, and Hamilton, that the source of the bleeding was the placenta, logically concluded that the right treatment was to wholly detach the placenta. The theory was wrong, and the practice worse than the old *accouchement forcé*. Since the total detachment of the placenta could hardly be accomplished without forcing the whole hand into the uterus. Fraught with peril to the mother, it was almost certainly fatal to the child. I mention this because it has been said in your issue of Feb. 26th that "Barnes' treatment—partial detachment"—is a modification of Simpson's. My theory and practice differ *toto cœlo* from Simpson's. I have taken special pains to show that the source of the

Digitized by Google

hæmorrhage is the same as that in post-partum hæmorrhage—namely, the uterus. Having cleared the ground of this misapprehension, let me state as briefly as it is possible the theory and practice now generally accepted. The uterus is divided into three zones—the fundal, the equatorial, and the lower. It is only placenta attached within the lower zone that makes placenta prævia. There is no necessary detachment of placenta attached to the two upper zones. The limits of the lower zone, that of dangerous placental attachment, are the os internum below and a circle closely defined by the equator of the child's head above. I must refer to my systematic works for the evidence of this. It is enough here to state that this boundary line was revealed to me by repeated clinical observation and deduction; and that this physiological discovery has since been confirmed by the anatomical researches of Bandl. In fact, Bandl's ring is identical with my boundary line between the lower and equatorial zones.

Treatment, then, flows from the fact that hæmorrhage often ceases when all placenta, or sometimes only a great part of it, growing within the lower zone, has been detached, active or passive uterine contraction taking place. Action is conducted on the following lines. Provoke uterine contraction. To do this we have first the old plan. (1) Puncture the membranes. (2) Apply a firm binder over the uterus. (3) If the cervix is small and rigid, pass a laminaria tent to dilate, watching carefully. (4) Pass in one or two fingers and detach all placenta *within reach of the fingers*. The sweep of the fingers very closely takes the lower zone. (5) Insert a Barnes' bag. This acts in three ways: it dilates the cervix; it provokes uterine action; it acts as a plug, compressing the mouths of the bleeding vessels. Now things are prepared for delivery. If the head presents, (6) apply forceps, or turn by the bipolar method. This plan gives the greatest security to the mother, and the best chance to the child.

In a typical case, coming under care from the beginning, all these expedients may come into use in succession. In those cases where we are called when flooding is furious, it may be necessary to introduce the hydrostatic dilator at once, or if the cervix is dilated enough—and very moderate dilatation is enough—it is advisable to turn. I will not trouble you with statistics. These have been sufficiently quoted by Dr. Murphy and Dr. Braxton Hicks. I believe that a wider adoption of the principles enunciated above will produce figures more satisfactory still.

I am, Sirs, yours faithfully,

Harley-street, March, 1887. ROBERT BARNES.

THE SOCIETY OF APOTHECARIES AND THE CONJOINT BOARD FOR ENGLAND.

To the Editors of THE LANCET.

SIRS,—May I be allowed to express my opinion on the question of admitting the Apothecaries' Society into the Conjoint Examining Board, as one of the licentiates of that Society. In 1860, after examination, being permitted to practise medicine within ten miles of London (an antiquated restriction), I was duly impressed with the high opinion entertained by boards of guardians of the L.S.A. qualification—an estimate to which I do not at present attach a high value. But now this handmaid of a wholesale and retail drug-shop is struggling to mix up surgery in the concern, and to force herself into society where she is not welcome. These futile efforts are, perhaps, allied to the erratic movements which frequently precede dissolution. In my opinion, the Apothecaries' Hall should ally herself with the Pharmaceutical Society, and should no longer perpetuate (by her association with our profession) one of the most vulgar prejudices that I have had and yet have to fight against—viz., the persistent idea that drugs occupy the first place in our treatment of disease. While rendering to the Society of Apothecaries full credit for her early improvements in education, I submit that, in the highest and best interests of our profession, *now* is a fitting time for a divorce; the Hall has her own proper course to hold, but on matters of high training, example, and social prestige, she may now write on her walls "Obsoleta per orbem dicor."

I am, Sirs, your obedient servant,

RICHARD DAVY,
Surgeon to the Westminster Hospital.

Welbeck-street, W., March 25th, 1887.

THE QUESTION OF RELATIVE RANK.

To the Editors of THE LANCET.

SIRS,—Touching the question of relative rank in the army, and the desire, apparently on the part of some medical officers to have their titles compounded of a medical and distinctive military one, I would like to ask, Is it not an undignified and false position for members of the medical profession to lead the public to believe that they cannot, as such, stand alone, but need the support of the reflected advantages of purely military titles, indicative of and appertaining to a profession to which they do not rightfully belong? What can the public think of such a proceeding? And, as a matter of policy or expediency, why should a Doctor of Medicine or a Fellow of the Royal College of Surgeons seek to obtain such titles?

I am, Sirs, yours faithfully,

March, 1887. F. R. C. P.

To the Editors of THE LANCET.

SIRS,—The abolition of "relative rank" in the army has not, as pointed out by you in a late number of THE LANCET, altered in any way practically the "status" of officers of the medical staff, but their position in the army remains as heretofore unsatisfactory and undefined, for "relative" rank is but a meaningless term, and carries with it no military rank. Now, why should the officers of the medical department be the only officers in the army who have no military standing, honorary or otherwise? Apart from their purely professional duties they have distinct military duties to perform—when doing duty with the Medical Staff Corps at headquarters, or in command of "detachments" of that corps, or on active service when attached to "bearer companies." Why, therefore, if called upon to perform purely military duties, are they not granted military rank? The quartermasters, warrant, and non-commissioned officers, &c., of the Medical Staff Corps have a defined military "status," but the officers who command them have no military rank. Surely this is an anomaly. Is the medical department not a necessary and integral part of the army organisation, and are the officers of that department any less entitled to a proper *locus standi* in the service than officers of other departments? Again, is the medical department a military or a purely civil department. If the latter, why should the medical officers be called upon to wear military uniform and to exercise military command over their corps? In desiring "honorary" rank, as giving them a defined military "status" in the army, the officers of the medical staff have no wish whatsoever to represent themselves otherwise than as medical men. They are proud of the noble profession of which they have the honour of being members, and would be sorry to lose the "title" of "surgeon," which distinguishes them from the regimental officer holding "substantive" rank. I would venture to suggest that "honorary" rank be granted to medical officers, the terms "surgeon-captain," "surgeon-major," up to "surgeon-general" being retained, the first part of the title showing that the officer was a medical officer, and the second part the honorary rank which such officer held in the army. In conclusion, I would add that the assertion which has been made that medical officers are desirous of obtaining purely military titles is erroneous and absurd, for they have nothing to gain and much to lose by obscuring the fact that they are medical men.

I am, Sirs, yours obediently,

March, 1887. MEDICAL STAFF.

EDINBURGH.

(From our own Correspondent.)

THE SCARLET FEVER EPIDEMIC.

IN connexion with the statement in my last week's note upon this subject, some doubt has been thrown upon the results of the investigation then detailed. It was reported that the source of the outbreak had been detected, and that the disease had been clearly traced to a dairy-farm in the country, from which a large part of the Edinburgh milk-supply is derived. The proprietor of this farm now writes

Digitized by Google

to the local papers, and with great show of reason on his side combats the opinion arrived at, and publicly expressed by Dr. Littlejohn and Bailie Russell. He points out that on Jan. 27th, when fever appeared at his farm, there were already ninety cases of scarlet fever in the city hospital, and that, as there were in all probability at least twice that number of cases in the city, not inmates of the hospital, the fever was already present in an epidemic form. This is a point of importance, and one that he can judge of as well as qualified medical experts, and if this contention on his part is found to be consonant with the facts of the case, he must without doubt be exonerated from the charge of having caused the whole of the recent epidemic and its accompanying mortality. His opinion of the precautions taken at his farm to prevent infection cannot of course have any weight against the skilled opinion that in some cases infection had been conclusively traced to milk supplied by him; nor can his strictures upon the supposed insanitary state of a western district of Edinburgh be taken as of any value; but if his first point is chronologically correct, our sanitary authority has still the task before it of tracing the course and origin of the initial epidemic, which appears to have been sufficiently alarming before the exacerbation due to the contaminated milk-supply had occurred. It is to be hoped that these aspects of the disease may be as thoroughly studied from the sanitary side as it is stated that its etiological aspects are now being studied from the experimental side in one of the university laboratories, and that in both respects the epidemic may be turned to account in the advancement of scientific knowledge.

END OF THE WINTER SESSION.

The lectures of the winter session came to an end on March 25th, when the results of the class and bursary competitions were announced and the work of the session formally wound up. In the class of physiology, Professor Rutherford said farewell to his students for a period of six months, for which time he has obtained leave of absence, indicating the arrangements that he hopes to carry out next winter, when he anticipates being again in his place. The roll of class honours in the various classes shows a high degree of excellence in the work done, a much larger proportion of students than in previous years having secured Honours certificates in the competitive examinations.

HOSPITAL ACCOMMODATION IN THE COUNTY OF MIDLOTHIAN.

The great lack of a fever hospital, which has long been felt in some parts of the county of Edinburgh, is shortly to be supplied. The site and plans for a combination hospital for a district comprising nine parishes and a population of 20,000 people were recently approved by a meeting of the committee of local boards appointed to further the matter. The new hospital is to be situated about six miles from Edinburgh, near enough for an Edinburgh physician to be placed on its honorary staff; it is to be erected on a healthy site, and is well isolated. It is to be a one-storeyed building, containing eighteen beds, and it will cost about £1600.

THE NEW PUBLIC BATHS.

The new public baths for the city are rapidly approaching completion, and will shortly be thrown open to the public. The Town Council have wisely decided that applicants for the post of superintendent must not only be good swimmers, but must be able to give instruction in the art.

Edinburgh, March 30th.

DUBLIN.

(From our own Correspondent.)

RICHMOND DISTRICT LUNATIC ASYLUM: ANNUAL REPORT.

At the close of last year the number of male patients exceeded the limits of nominal accommodation by twenty-three, and the institution contained twenty-two more than at the close of the previous year. The admissions during 1886 numbered 433, and an unusual number exhibited suicidal propensities. A severe form of dysentery occurred during September, and lasted several months. Nine deaths took place from it, and thirteen deaths from diarrhœa, which was very prevalent, ninety-five cases having been treated. Dr. Conolly Norman, the resident medical superintendent, speaks very unfavourably as to the sanitary condition of the asylum. The soil pipes, he states, are unventilated, owing to the absence of a counter opening, while no attempt has been made to ventilate the waste-pipes from baths, sinks, &c. There is no proper trapping, and there are no fresh-air breaks. Further, the house drains are usually brought under the buildings, and the pipes are not jointed with cement. As the asylum stands very high, and as the River Bradog, after leaving the asylum grounds, runs through a densely-inhabited portion of the city, the area of sewers thus ventilated into the various apartments must be very extensive. As Dr. Norman well remarks, with such conditions it can only be wondered that more sickness does not exist, and that the death-rate is not higher than at present. The baths also are insufficient in number, the kitchen small and ill-provided with cooking apparatus, the laundry small and ill-fitted; while in the decoration, furniture, &c., of the wards, this asylum is below the standard of most similar institutions at the present day. From these details, which could be supplemented by numerous others, it will be seen that the sanitary arrangements of this large and important institution require, in the interests of the inmates, a thorough overhauling, and various improvements carried out before its condition can be regarded as satisfactory.

DUBLIN HOSPITALS COMMISSION.

The report of this Commission, which held its meetings about twelve months since, has not yet been issued, but, as Mr. Balfour stated last Monday that it would be submitted to the Lord-Lieutenant this week, it probably will not much longer be delayed. It is believed that the Commissioners had great difficulty in coming to any agreement on the subject of their report.

THE QUEEN'S JUBILEE.

Sir George Porter, D.L., Surgeon-in-Ordinary to Her Majesty in Ireland, and high sheriff for the co. Wexford, has given in honour of Her Majesty's Jubilee twenty guineas to the County Wexford Infirmary, a similar amount to the Wexford Branch of the Royal Lifeboat Institution, and twenty guineas to the poor of Wexford. It is to be hoped that such an example of generosity may be widely followed.

SAD ACCIDENT TO A MEDICAL MAN.

On Tuesday morning Dr. Arthur Switzer, of Dublin, fell from his bedroom window, some 40 ft. in height, on to the pavement, and received such injuries that he died shortly after his removal to hospital. It is supposed that while looking out of the window he overbalanced himself and thus caused the accident. The deceased was only in his twenty-fifth year, and was a graduate in Arts, Medicine, and Surgery of the University of Dublin, and obtained various distictions during his university career. Only a few days before his death he had received an appointment in the country. Much sympathy is felt with his family in their sad bereavement.

Dr. L. A. Byrne has been presented with some surgical and midwifery instruments and a microscope by the officers of the Dublin Corporation on his resigning the position he had held in connexion with the executive of the Public Health Department.

The final tie for the Dublin Hospital Challenge Cup was decided on Monday last, the gate money being given in aid of the funds of the Royal Medical Benevolent Fund Society of Ireland.

BELFAST.

(From our own Correspondent.)

QUEEN'S COLLEGE, BELFAST.

Two schemes are already before the public in connexion with the Queen's jubilee: one is to build a consumption hospital, and the other a convalescent home, as an addition to the Children's Hospital; and now the President of Queen's College in a public letter suggests a third scheme on behalf of the College. After pointing out the great progress the College has made since its foundation in 1849, as shown by the large number of students who have passed through its class-rooms, and the fact that its great educational work has been done without any aid from local or private funds, the President states that a difficulty pressing heavily on the College at present is the unexpected refusal of Her

Digitized by Google

Majesty's Government to enlarge the buildings and provide laboratories. Recently, after applying again to the Government, the President received a decided answer to this effect: "The College was built, endowed, and enlarged by the State. The people of Belfast have derived great advantage from it; they have hitherto given nothing to it; and now upon them must rest the duty and responsibility of making such additions and improvements as are required by the increased number of students, and by an enlarged, and gradually enlarging sphere of usefulness." The President states that what is wanting is larger buildings, new laboratories, modern appliances, especially in the practical departments of chemistry, natural philosophy, engineering, and physiology; and he states £8000, judiciously expended, would enable the work to be carried out; and he thinks it would be a graceful act for the loyal people of Belfast and Ulster, on the Jubilee of the Queen, to place the College in a position to carry out fully the great object for which it was formed. In concluding his letter, the President appeals for assistance to those who received their early education in Queen's College, and who now occupy places of high distinction and emolument in various parts of the world.

BELFAST OPHTHALMIC HOSPITAL.

The annual meeting of the supporters of this hospital was held on March 22nd, when the Mayor of Belfast presided. Dr. Walton Browne presented the surgical report, from which it appears that 1000 eye cases, 253 ear cases, and 80 throat-cases have been treated, and 90 patients have been admitted to the wards of the hospital, making a total of 1423 persons treated during the year. The average attendance of out-patients has been 500 per month. Cocaine has been used in nearly all the operations, doing away with the necessity for the administration of chloroform or ether. As in former years, a large class of students are attending the hospital. Application has been made to the Royal University to have the certificates of that institution recognised, so that the students attending the classes would have the advantage of such recognition. Owing to the death of Dr. Thomas Henry Purdon, a vacancy now exists on the consulting staff. Reference was made to the loss the charity had sustained in the deaths of Sir Wm. G. Johnston, D.L., Rev. W. C. M'Cullagh, and Dr. Purdon.

Belfast, March 29th.

PARIS.

(*From our own Correspondent.*)

INDUCED SOMNAMBULISM IN ITS MEDICO-LEGAL ASPECTS.

M. MESNET related the history of a patient under his care at a recent meeting of the Academy of Medicine. A young man, nineteen years old, whose mother was the subject of hysteria, had had fits of somnambulism from the age of fourteen. These became so frequent by day as well as by night that he was discharged by his employers. Besides the fits of sleep he has general anæsthesia and analgesia, together with complete loss of taste and smell. At the end of last year he was admitted to the hospital. As a matter of course, he was at once utilised for experiment in hypnotism, and was found to be easily induced into the state of "hypnotic fascination" by the magnetic stare, and as easily awakened by being blown upon the face. It was interesting, says M. Mesnet, to ascertain whether this young man was accessible to post-hypnotic suggestion. Having been sent to sleep as usual, he was imperiously ordered to take the watch of one of the students on the following day, and then to endeavour to make his escape. At the appointed time, which was at the usual visiting hour, he was seen to look contemplatively at the student's chain; he soon became fascinated by the shining links, and, after several struggles against the suggestion, he could resist no longer, and, detaching the chain, made an attempt to escape. When awakened, and the watch taken from his pocket, he was unable to account for its possession, but protested his innocence and burst into tears. This shows, says M. Mesnet, that a thief or assassin who cannot explain his acts, and declares he has no recollection of them, may be an unconscious agent. Although a magistrate will not believe his negation, he may have no knowledge of what he has done. Prossic persons may hesitate to accept M. Mesnet's conclusions, but the fascinative action of watch chains is now placed beyond doubt; and those who are affected with this variety of hypnotism in its chronic form will appreciate his soundness of observation.

HYPODERMIC INJECTIONS IN SYPHILIS.

The treatment of syphilis by hypodermic injections of mercury continues to gain ground, but the selection of the best preparation has given rise to discussion. At the Société Médicale des Hôpitaux, M. Balzer read a paper on the hypodermic injection of calomel in oil of vaseline. Calomel, first injected hypodermically by Scarenzio, is said to change slowly under these circumstances into mercuric chloride. Four injections of two grains each, at intervals of three weeks, suffice to cure the secondary symptoms. The only drawback is the occasional formation of abscesses, which occur in 14 per cent. of the cases. M. du Castel said that the hypodermic method was excellent, but that it was a great improvement to substitute the yellow oxide for the subchloride. With this preparation there is little pain, and in his last series there was no abscess. At the Société de Thérapeutique, M. Martineau brought forward some massive statistics concerning the ammoniacal peptonate of mercury which had been incriminated by M. Hallopeau. He had, he said, treated 6000 patients, and made at least 180,000 injections. Every kind of symptom, including ulcerative syphilides and cerebral syphilomata, could be dissipated by it, and, thanks to these injections, there is no longer anything to fear; syphilis can be mastered with certainty. M. Martineau had never once seen an abscess when the injection was made in the cellular tissue.

BRIGHT'S DISEASE AND ALBUMINURIA.

The *Semaine Médicale* publishes an interesting lecture by Professor Dieulafoy, chiefly dealing with the diagnosis of Bright's disease. He points out that in a great many people albuminuria may exist without nephritis. Leube found this to be the case five times in 119 soldiers, and nineteen times in the same number of men after a long march. Albumen is often found in the urine during an acute disease, such as pneumonia or pleurisy, and disappears upon convalescence without any evil result. A number of theories have been suggested to explain this occurrence. Of these may be mentioned the opinion of Professor Jaccoud, who thinks that the albuminous material is not true albumen, or serine, but a variety of it called globuline, derived from the blood-cells, and distinguished from the first by its coagulability with concentrated solutions of sulphate of magnesia. In these cases the toxicity of the urine is normal. Bright's disease may last, on the other hand, not only during the pre-albuminuric stage of Mahomed, but even during the whole of its course, without its being possible to detect any trace of albumen in the urine. If general symptoms point in this direction, and the probability of arterio-sclerous nephritis is enhanced by the discovery of a *bruit de galop*, or of the *doigt mort*, a pathognomonic sign pointed out by M. Dieulafoy, the test of Feltz and Ritter, as simplified by Professor Bouchard, will settle the question. The urine of a healthy person when introduced into the circulation of the rabbit by injection into the veins of the ear kills the animal in the proportion of fifty grammes per kilogramme of weight. But that of albuminuric subjects can be tolerated in much larger doses, and in one case mentioned by M. Dieulafoy a rabbit of two kilogrammes, for which a toxic dose of healthy urine would be 100 grammes, exhibited no discomfort until 260 had been injected, and even then recovered.

Paris, March 28th.

Obituary.

W. H. THORNTON, J.P., M.R.C.S.

MR. W. H. THORNTON, of Berkeley Lodge, Margate, died at Hastings, on Sunday, March 20th, of congestion of the lungs. He was the son of the late Mr. W. Thornton, was born at Uxbridge in 1822, and was educated at Charing-cross Hospital. Mr. Thornton went to Margate in 1845, and had been in active practice in that town for forty-two years. For twenty years he was one of the visiting surgeons to the Royal Sea-bathing Infirmary, and for the same period surgeon to the Deaf and Dumb Asylum. Mr. Thornton was an honour to his profession, upheld its dignity, and

Digitized by Google

was loyal in his dealings with his brother practitioners. As a surgeon he was conservative, and preferred gentle to more heroic measures. He took the keenest interest in his work, and would at all times sacrifice his own comfort to promote the welfare of his patients. What, however, will chiefly dwell in the memory of his friends was his kindness and goodness of heart. He was full of charity, and was one of those who thinketh no evil. He had the happy gift of seeing the best and brightest side of everything and everybody, and his cheery and sympathising manner helped his patients not a little. Rich and poor alike feel his loss, and his funeral was attended by most of the inhabitants. He is mourned by all, but by none more than his medical brethren.

Medical News.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—At a meeting of the Court of Examiners held on March 21st and following days, the undermentioned gentlemen passed the first half of the examination for the Letters Testimonial of the College:—

Edward C. Clanchy. | Edmond F. Hayes.
Andrew G. T. Hanks. | Thomas Hickey.
John Lundie.

SOCIETY OF APOTHECARIES.—The following gentlemen passed the examination in the Science and Practice of Medicine, Surgery, and Midwifery, and received certificates to practise on March 24th:—

Carter, Robert James, The Grove, Camberwell.
Jecks, Cyril William, Hilldrop-road, Camden-road.

THE annual Hospital Sunday collections were held in Warrington on the 27th ult.

THE Earl of Dunraven has consented to preside at a festival dinner to be held in aid of the funds of St. Mary's Hospital.

MR. FRANCIS POWELL has on the *tapis* a Bill to regulate and control the employment of children in hawking articles in the street.

THE annual meeting of the supporters of the Worcester Dispensary was held on the 29th ult., when satisfactory reports were presented and adopted.

ON the 24th ult. a Local Government Board inquiry was held at Porth relative to the pollution of the River Rhondda by refuse from certain collieries adjacent to it.

AN epidemic of diphtheria has broken out in one of the suburbs of Canterbury, and there have been several fatal cases. A similar outbreak occurred in the same suburb last year. The cause is unknown.

ON the 26th ult. the sixty-third annual meeting of the Royal National Lifeboat Institution was held, when it was stated that the committee had decided to submit their boats to more severe tests than heretofore as regards self-righting properties.

INFECTIOUS DISEASE AT DARLINGTON.—The Sunday Schools at Darlington have been closed, as all but one or two of the elementary schools have been for some time, because of the great prevalence of scarlet fever and measles in the town. The public library has also for the same reason been closed for three weeks.

AT a special meeting of the governors of the Bradford Fever Hospital on the 25th ult. it was decided, subject to certain conditions, to sell the hospital to the corporation for £10,000. Part of this sum is to be devoted to the provision of a hospital or hospitals for the reception of persons suffering from infectious diseases in the townships or districts outside the borough, the sanction of Parliament being asked for such appropriation.

THE PASTEUR INSTITUTE.—The members of the committee of the Pasteur Institute have decided to refuse the site offered by the municipality, and to purchase a site for 430,000 francs. They have also agreed on plans for the erection of four buildings, to cost 60,000 francs. A yearly revenue of 65,000 francs has been secured, leaving 35,000 still to be obtained, and the subscription lists are to be kept open until the desired sum is collected.

AT a meeting in support of the fund now being raised on behalf of Guy's Hospital, held on the 30th ult. at the Surrey Masonic Hall, Camberwell, the sum of £62 was subscribed.

HOSPITAL SATURDAY FUND.—At a meeting of the delegates of this fund on the 26th ult., the secretary reported that as the result of the first year's work of the Surgical Appliance Committee 540 patients had been supplied with surgical instruments, at an average cost of 10s., the attendances recorded being 695. A grant of 4 per cent. for the purchase of appliances for the requirements of the present year was agreed upon.

THE SANITARY INSTITUTE.—A petition has been presented to Her Majesty in Council by the Duke of Cambridge, the Duke of Northumberland, the Duke of Westminster, and others, on behalf of the Parkes Museum of Hygiene and the Sanitary Institute of Great Britain, praying for the grant of a charter of incorporation, under the name of the Sanitary Institute. The petition will be considered by a Committee of the Privy Council on May 6th.

PRESENTATIONS.—On the 22nd ult. Mr. Blackburn was presented with a silver goblet by the members of the Monk Bretton Colliery St. John Ambulance Classes in recognition of his services as instructor.—Mr. A. W. Hughes has been presented with an address and several cases of surgical instruments by the students of anatomy, Surgeons' Hall, Edinburgh, on the occasion of his resigning the post of Senior Demonstrator of Anatomy in the Edinburgh Royal College of Surgeons.

ACCOMMODATION FOR UNTRIED PRISONERS AT THE CENTRAL CRIMINAL COURT.—At a meeting of the Court of Common Council at Guildhall on the 24th ult., a letter was read from the Home Office asking for information as to what steps the Corporation intend to take to bring the accommodation for untried prisoners at the Central Criminal Court up to the standard indicated by the Committee which recently inquired into the subject. The letter was referred to the Law and City Courts' Committee.

LOCAL GOVERNMENT IN THE CITY.—The report on the work executed by the Commissioners of Sewers of the City of London for the year 1886 has just been issued by Colonel Haywood, the engineer to that body. The report gives a comprehensive statement of the sewers, house drainage, dangerous structures, improvements, electric lighting, water-supply, scavenging, cemetery arrangements, artisans' dwellings, and other matters which have occupied the attention of the commissioners during the past twelve months.

THE MELBOURNE HOSPITAL.—From the annual report of this institution it appears that during last year the income for the purposes of maintenance, inclusive of £14,000 from the Parliamentary vote and £2806 from the committee of the Hospital Sunday Fund, amounted to £23,362. The expenditure was £24,861. The benefits of the hospital were extended to 19,398 cases, of which number 15,687 were out- and 3791 in-patients. The report records several alterations in the buildings, which have been undertaken to improve the sanitary condition of the institution, an object which has, it is stated, been fully achieved. The erection of a hospital for the reception and treatment of persons suffering from consumption, and the removal of the institution to another site, could a suitable one be obtained, is advocated by the committee.

MEDICAL NOTES IN PARLIAMENT.

Anthrax.

IN the House of Commons on the 25th ult., in reply to Dr. Cameron, Lord John Manners stated that the Anthrax Order of 1886 provides for the destruction of carcasses of animals dead of anthrax by exposure to a high temperature or by chemical agents, and some local authorities in districts where the necessary appliances exist, have been authorised to adopt such modes of destruction instead of burial. In reference to burial, which in many parts of the country is the only available method of disposing of carcasses, local authorities have been warned that the carcasses should be buried entire and be well covered with lime. Mr. Ritchie also stated, in reply to Dr. Cameron, that the danger of anthrax being communicated to human beings is one almost exclusively incurred by those who have to deal with the hides or opened bodies of infected animals, and obedience to the Order of the Privy Council of Sept. 16th, 1886, as to dealing with such animals and their carcasses, will practically

Digitized by Google

get rid of that danger. No other measure is regarded as called for. He added that the report of the medical officer of the Board for 1882 contains a memorandum which was prepared in order to give the means of recognising anthrax as it affects people dealing with hides, and this memorandum might be useful as guarding against error in diagnosis in districts where actual anthrax has appeared.

On the 29th ult., in reply to Mr. Gardner, Lord J. Manners said that experiments in inoculation with the virus of anthrax and other diseases are being carried on, but up to the present the results are not so satisfactory as to justify any recommendation as to its general adoption in this country.

Surgeon-Major Moore.

On the 28th ult. Dr. Robertson asked the Secretary of State for War whether it was the case that Surgeon-Major Sandford Moore, who originated and introduced into the Army the present ambulance system for the removal of the wounded from the field of battle, had been obliged to retire on the lowest rate of pension, in consequence of total and permanent blindness, induced, in the opinion of a medical board, by his extra literary duties; and whether, under those circumstances, he would take into consideration the justice of granting to that officer some additional pension to meet the increased expenses necessitated by his disability.—Mr. H. Stanhope replied that the case of Surgeon-Major Moore was a very sad one, and that there was every disposition to approach it with the utmost possible indulgence. But he regretted to say that he found himself unable after very careful consideration to grant an additional pension to an officer whose ill-health takes the form of loss of eyesight.

Purification of the Thames.

On the 29th ult., in reply to Colonel Dawnay, Mr. Ritchie stated that he had been in communication with the Conservators of the River Thames on the subject of their proposed bye-law prohibiting the casting or suffering to fall or flow into the river any sewage or other offensive matter, and the effect of that bye law with regard to house-boats and steam launches. The Conservators had forwarded to him a copy of a letter which, as soon as the bye-law referred to has been approved, they propose to address to the owners of house-boats and steam launches, requesting that they will, without delay, make the necessary arrangements in the fittings of their vessels, in order to comply with the bye-law referred to. They state that any closet communicating with the river would obviously be an infraction of the bye-law, and cannot therefore be permitted.

Scotch Universities Bill.

In answer to Mr. Bryce, the Lord Advocate said that the promised Bill dealing with the question of the Scotch Universities would probably have been introduced by this time had it not been for the delay caused by the change of office of the late Secretary for Scotland. It was hoped, however, to introduce it shortly.

When the Civil Service Estimates are again before the House of Commons, Mr. A. O'Connor will propose, on the vote for the Local Government Board, to move to leave out the item of £16,500 on account of public vaccinators.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ADDERLEY, JOHN, M.D., M.Ch.Q.U.I., has been appointed Medical Officer for the Glengariffe Dispensary District, co. Cork, vice Levis, resigned.

BRADSHAW, THOMAS R., B.A., M.D.Univ.Dub., M.R.C.S., has been appointed Honorary Physician to the Stanley Hospital, Liverpool, vice Barr, resigned.

CHAMBERS, ANTONY B., M.D., M.Ch.Roy.Univ. Irel., has been appointed Resident Medical Officer of Health for Long Eaton, vice Butler, resigned.

COLLYER, JAMES, L.R.C.P.Lond., M.R.C.S., has been appointed Medical Officer to the Chase Farm Schools of the Edmonton Union.

DAVIES, JOSEPH, L.R.C.P.Ed., F.R.C.S.Ed., has been appointed Medical Officer for the Second District of the Swansea Union.

DOYLE, HENRY MARTIN, M.R.C.S., L.S.A., has been appointed Receiving Room Officer to the London Hospital.

EVANS, EDWARD B., L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Fifth District of the Swansea Union.

GIBSON, THOMAS B., M.A., M.B., C.M.Aber., has been appointed Medical Officer by the Oldmachar Parochial Board, Aberdeen, vice Fraser, deceased.

HARRIS, H. E., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant Medical Officer for the Infirmary of the Parish of Paddington.

LUFF, ARTHUR PEARSON, B. Sc. Lond., M.R.C.S., L.S.A., has been appointed to the Chair of Medical Jurisprudence and Toxicology in St. Mary's Hospital Medical School, vice Randall, M.D., resigned.

LYON, THOMAS GLOVER, M.A., M.D.Cantab., M.R.C.P.Lond., has been appointed Assistant Physician to the North-West London Hospital.

MACKINTOSH, ANGUS, M.D., L.F.P.S. Glas., has been reappointed Medical Officer of Health for the Clay Lane Urban District of the Chesterfield Union.

PECK, EDWARD GEORGE, M.A., M.R.C.S., has been appointed Resident Medical Officer to the Chelsea Hospital for Women, Fulham-road, S.W., vice Sunderland, whose term of office has expired.

POCKETT, LEWIS W., M.R.C.S., L.S.A., has been appointed Medical Officer for the Hogathorpe District of the Spilsby Union.

POTTER, E. FURNISS, M.R.C.S., L.R.C.P. Lond., has been appointed Visiting-Surgeon for the North Myton District of the Hull and Sculcoates Dispensary.

POWER, D'ARCY, M.A., M.B.Oxon., F.R.C.S.Eng., has been appointed Surgeon to the Metropolitan Dispensary, Fore-street, E.C., vice Alban Doran, F.R.C.S.Eng., resigned.

STEDMAN, ARTHUR, M.R.C.S., L.S.A., has been reappointed Medical Officer for the Effingham District of the Dorking Union.

STORRAR, WILLIAM MORRISON, L.R.C.S., L.R.C.P. Ed., has been appointed Medical Officer for the Eastham District of the Wirral Union.

WILLIAMS, ROGER D. D., L.R.C.P.Ed., M.R.C.S., has been appointed Medical Officer for the Fourth District of the Swansea Union.

Vacancies.

In compliance with the desire of numerous subscribers, it has been decided to resume the publication under this head of brief particulars of the various Vacancies which are announced in our advertising columns. For further information regarding each vacancy reference should be made to the advertisement.

BRADFORD INFIRMARY AND DISPENSARY.—House-Surgeon. Salary £110 per annum, with board and washing.

BRITISH MEDICAL ASSOCIATION.—Research Scholar. £150 per annum.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Physician.

DENTAL HOSPITAL OF LONDON, Leicester-square.—Dental Surgeon.

GLOUCESTER COUNTY ASYLUM.—Third Assistant Medical Officer. Salary £105 per annum, with board, lodging, and washing.

NEW HOSPITAL FOR WOMEN, Marylebone-road.—Clinical Assistant.

PADDINGTON-GREEN CHILDREN'S HOSPITAL.—House-Surgeon. Salary £80 per annum, and rooms.

POPLAR UNION.—Medical Officer for the East District. Salary £130 per annum, to include all extra fees, the guardians supplying drugs.

QUEEN'S HOSPITAL, Birmingham.—Obstetric and Ophthalmic House-Surgeon. The appointment carries with it board, lodging, &c.

SCARBOROUGH FRIENDLY SOCIETIES' MEDICAL ASSOCIATION.—Resident Medical Officer. Salary £200 for the first year, £220 for the second (if satisfactory), with fees extra, and residence, free of rates and taxes, with an allowance for coals and gas.

UNIVERSITY OF CAMBRIDGE.—John Lucas Walker Student. £250 per annum.

Births, Marriages, and Deaths.

BIRTHS.

BARRY.—On the 26th ult., at Linton Court, Settle, the wife of F. W. Barry, M.D., of a daughter.

HOWELL.—On the 24th ult., at East-hill, Wandsworth, S.W., the wife of James Bromley Howell, M.R.C.S., of a son.

MACLEOD.—On the 28th ult., at the East Riding Asylum, Beverley, the wife of M. D. Macleod, M.B., of a daughter.

MASTERS.—On the 26th ult., at Westall House, Brook-green, W., the wife of John Alfred Masters, L.R.C.P. Lond., M.R.C.S., of a daughter.

MULLIN.—On the 18th ult., at Ruthin-gardens, Cardiff, the wife of James Mullin, M.A., M.D., of a son.

WALLACE.—On the 24th ult., at Guernsey, the wife of A. C. Wallace, M.R.C.S., of a daughter.

MARRIAGES.

PIERCE—BRANDON.—On the 22nd ult., at St. Bede's Church, Liverpool, Evan Pierce, M.D., F.R.C.S., J.P., Coroner for West Denbighshire, to Alathea Eliza, youngest daughter of the late Thos. Brandon, of Brondesbury-park, N.W.

PRIESTLEY—JACQUES.—On the 12th ult., at the Parish Church, Streatham, S.W., Joseph Priestley, B.A., M.D., to Edith Blanche, youngest daughter of Edwin Jacques, M.D., of Brixton, S.W.

DEATHS.

ALLEN.—On the 21st ult., Thomas Allen, M.D., M.R.C.S., aged 61, late Medical Superintendent and Director of the Government Lunatic Asylum, Kingston, Jamaica.

BRADY.—On the 27th ult., at Loddington House, Rugby, John Brady, M.R.C.P.Lond., F.R.C.S.I., for twenty-seven years M.P. for county Leitrim, aged 74.

COLLIE.—About Oct. 15th, last, lost by the wreck of the ship *Norbudda*, David Collie, M.D., of Edinburgh.

HUTTON.—On the 27th ult., at Lowndes-street, S.W., Charles Hutton, M.D., aged 69.

MATHEW.—On the 22nd ult., at Bruges, Theobald Mark Mathew, late Deputy Surgeon-General, H.M.'s Indian Army, in his 54th year.

RUTHERFORD.—On the 24th ult., at Vauxhall-bridge-road, S.W., Surgeon-General Wm. Rutherford, M.D., C.B., Honorary Physician to the Queen, aged 71.

SWEETING.—On the 25th ult., at Great Smeaton, Yorkshire, George Bacon Sweeting, M.R.C.S.Eng., L.R.C.P.Lond., Consulting Surgeon to the West Norfolk and Lynn Hospital, of King's Lynn, aged 63.

THURLAND.—On the 23rd ult., at Wilmington-square, W.C., Francis Edward Thurland, M.R.C.S., aged 40.

YEO.—On the 27th ult., at Alverstoke, Hants, Gerald A. Yeo, F.R.C.S., retired Fleet Surgeon, R.N.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Medical Diary for the ensuing Week.

Monday, April 4.

ROYAL LONDON OPHTHALMIC HOSPITAL, MOORFIELDS.—Operations, 10.30 A.M., and each day at the same hour.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL.—Operations, 1.30 P.M., and each day at the same hour.

CHELSEA HOSPITAL FOR WOMEN.—Operations, 2.30 P.M; Thursday, 2.30.

ST. MARK'S HOSPITAL.—Operations, 2 P.M.; Tuesday, 2.30 P.M.

HOSPITAL FOR WOMEN, SOHO-SQUARE.—Operations, 2 P.M., and on Thursday at the same hour.

METROPOLITAN FREE HOSPITAL.—Operations, 2 P.M.

ROYAL ORTHOPÆDIC HOSPITAL.—Operations, 2 P.M.

CENTRAL LONDON OPHTHALMIC HOSPITALS.—Operations, 2 P.M., and each day in the week at the same hour.

ROYAL INSTITUTION.—5 P.M. General Monthly Meeting.

ODONTOLOGICAL SOCIETY OF GREAT BRITAIN.—8 P.M. Casual communications by Messrs. J. Ackery, F. Henri Weiss, Boyd-Wallis, C. V. Cotterell, S. J. Hutchinson, W. Harrison, and J. Penfold.—Mr. Newland Pedley: On the Pathology of Pyorrhœa Alveolaris.

MEDICAL SOCIETY OF LONDON.—8.30 P.M. Sir Dyce Duckworth: A case of Ulcerative Endocarditis.—Mr. R. W. Parker: On the Alleged Dangers of Starch-containing Foods during the period of Infancy.—Dr. Whipham: A case of Exfoliating Eruption of the Tongue.

Tuesday, April 5.

GUY'S HOSPITAL.—Operations, 1.30 P.M. and on Friday at the same hour. Ophthalmic Operations on Monday at 1.30 and Thursday at 2 P.M.

ST. THOMAS'S HOSPITAL.—Ophthalmic Operations, 4 P.M.; Friday, 2 P.M.

CANCER HOSPITAL, BROMPTON.—Operations, 2.30 P.M.; Saturday, 2.30 P.M.

WESTMINSTER HOSPITAL.—Operations, 2 P.M.

WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

ST. MARY'S HOSPITAL.—Operations, 1.30 P.M. Consultations, Monday, 1.30 P.M. Skin Department, Monday and Thursday, 9.30 A.M.

SOCIETY FOR THE STUDY AND CURE OF INEBRIETY.—4 P.M. Annual Address by the President (Dr. Norman Kerr): The Pathology of Inebriety.—Dr. T. D. Crothers: The Cause and Cure of Inebriety.

PATHOLOGICAL SOCIETY OF LONDON.—8.30 P.M. Mr. Hutchinson, jun.: Alveolar Ulceration in a Child, General Tuberculosis.—Dr. Joseph Coats: (1) Hypertrophic Goitre with Secondary Tumours in Bones of Skull; (2) Tumour of Pineal Gland.—Mr. Lawson Tait and Mr. Doran: Specimens illustrative of Chronic Inflammatory Disease of the Uterine Appendages.—Mr. Bowlby: Congenital Dislocation of Hip.—Mr. Lunn: Disease of the Humerus.—Dr. Hale White: Meningeal Hæmorrhage with Secondary Degeneration of Spinal Cord.—Dr. Pitt: Carcinoma of Spine and Liver. Card Specimens:—Dr. Hale White: (1) Peripheral Neuritis; (2) Dilatation of Ureter and Hydronephrosis of One Side secondary to Urethral Stricture.—Mr. Shattock: Two Specimens of Osteomalacia, showing Metaplasia of the Osseous Substance into Fibrous Tissue.—Mr. Lockwood: Fœtus showing Absence of Margin of Acetabulum and other Abnormalities.—Dr. Turner: Congenital Stricture of Jejunum.—Mr. D'Arcy Power: Sequel to a case of Endosteal Sarcoma.—Dr. Thin (for Dr. B. Rake): Drawings of Leprosy Bacillus.—Mr. F. W. Clark: Acute Pericarditis.

Wednesday, April 6.

NATIONAL ORTHOPÆDIC HOSPITAL.—Operations, 10 A.M.

MIDDLESEX HOSPITAL.—Operations, 1 P.M.

ST. BARTHOLOMEW'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour. Ophthalmic Operations, Tuesday and Thursday, 1.30 P.M. Surgical Consultations, Thursday, 1.30 P.M.

ST. THOMAS'S HOSPITAL.—Operations, 1.30 P.M.; Saturday, same hour.

LONDON HOSPITAL.—Operations, 2 P.M.; Thursday & Saturday, same hour.

GREAT NORTHERN CENTRAL HOSPITAL.—Operations, 2 P.M.

SAMARITAN FREE HOSPITAL FOR WOMEN AND CHILDREN.—Operations, 2.30 P.M.

UNIVERSITY COLLEGE HOSPITAL.—Operations, 2 P.M.; Saturday, 2 P.M. Skin Department, 1.45 P.M.; Saturday, 9.15 A.M.

ROYAL FREE HOSPITAL.—Operations, 2 P.M., and on Saturday.

KING'S COLLEGE HOSPITAL.—Operations, 3 to 4 P.M.; Friday, 2 P.M.; Saturday, 1 P.M.

CHILDREN'S HOSPITAL, GREAT ORMOND-STREET.—Operations, 9 A.M.; Saturday, same hour.

PARKES MUSEUM OF HYGIENE.—5 P.M. Mr. J. Bailey-Denton: Metropolitan Sewage Disposal.

OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Dr. M. Handfield-Jones and others. Dr. Champneys: The Third Stage of Labour (the separation and expulsion of the placenta).—Dr. Matthews Duncan: Hæmorrhagic Parametritis.

Thursday, April 7.

ST. GEORGE'S HOSPITAL.—Operations, 1 P.M. Ophthalmic Operations, Friday, 1.30 P.M.

CHARING-CROSS HOSPITAL.—Operations, 2 P.M.

NORTH-WEST LONDON HOSPITAL.—Operations, 2.30 P.M.

Friday, April 8.

ROYAL SOUTH LONDON OPHTHALMIC HOSPITAL.—Operations, 2 P.M.

Saturday, April 9.

MIDDLESEX HOSPITAL.—Operations, 2 P.M.

Notes, Short Comments, & Answers to Correspondents.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

All communications relating to the editorial business of the journal must be addressed "To the Editors."

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news-paragraphs should be marked and addressed to the Sub-Editor.

Letters relating to the publication, sale, and advertising departments of THE LANCET *to be addressed "to the Publisher."*

We cannot undertake to return MSS. not used.

REGISTRATION OF AMERICAN GRADUATES.

Yankee.—The Medical Council has not yet come to any decision as to American degrees. The curriculum of two years common in American schools is not likely to be approved by the Council; but nothing is settled.

Dr. Hermet (Paris).—We regret we cannot aid our correspondent, as we are not in possession of the publication mentioned.

Poseidon.—The office of the Crown Agents for the Colonies, Downing-street, S.W.

Sir Jas. Sawyer.—The notice will appear next week.

VACCINATION AND REVACCINATION.

To the Editors of THE LANCET.

SIRS,—In your issue of March 19th, Dr. W. Sinclair Thomson states that "he has advised vaccination and revaccination on the thigh in preference to the arm or any other part." This position no doubt in infancy has its advantages; but later on in life it might possibly prove rather inconvenient. I fully agree with Dr. Thomson, though for a different reason, that it is especially for women that the question of site is of so much importance. For example, suppose a grown-up female who had been vaccinated in her thigh during infancy presents herself for the purpose of being medically examined for, say, life insurance, now, in answering the question whether she had been properly vaccinated, as most insurance offices require one to do, would it not be awkward in this case, if not indelicate, to be obliged to ascertain the fact by ocular demonstration?

I am, Sirs, yours faithfully,

March, 1887. J. H. BALFE, L.R.C.P.Ed. &c.

SNAKE-POISON.

To the Editors of THE LANCET.

SIRS,—Allow me to remark upon your recent article on snake-poisons that the researches of Dr. Wolfenden (Journal of Physiology, vol. vii., pp. 327-364) tend to show that these poisons are *not* of a chemical nature. This would seem to confirm the deduction made—viz., "that they do not fall into the class of alkaloids which result from organised vital activity."

I am, Sirs, your obedient servant,

March 28th, 1887. WILLIAM SQUIRE, M.D.

*** We are obliged to our correspondent for the reference to Dr. Wolfenden's researches, which would seem to support the conclusions arrived at by Drs. Weir Mitchell and Reichert. Gautier alone claims to have found a ptomaine in cobra venom.—ED. L.

Digitized by Google

DRINKING IN THE UNITED STATES.

THE *Pall Mall Gazette* remarks on the fact of the amount spent on drink in the United States. New York alone consumes annually 6,000,000 barrels of beer. The United States spend on intoxicants annually £170,000,000, or more than £400,000 a day all the year round. The folly of such an expenditure is monstrous, though we are not in a position to throw stones at our "cousins."

Mr. F. C. Cory.—The fee of one guinea is monstrously inadequate for time, services, and travelling expenses in the case of our correspondent. Even if he made no agreement beforehand, he is entitled to claim fair remuneration, and could enforce the claim by action at law. The Treasury have no more right than a private individual to engage a practitioner at their own estimate as to fee. By saying that he was "summoned," we presume our correspondent means that he was *requested* to attend at Whitehall. We would advise him to explain to the solicitor all the incidental expenses, direct and indirect, and to appeal to his sense of fairness.

Mr. C. J. Ribton Turner.—We have, unfortunately, no recollection of the case.

Dr. D. Donald.—The letter will be forwarded.

THE SELFISH PRINCIPLE AND MEDICAL ETIQUETTE.

To the Editors of THE LANCET.

SIRS,—I was once a great believer in medical etiquette. I am not so full of faith now; still, however, it is a beauteous thing when it is occasionally seen. But circumstances have forced themselves upon me, in, I believe, not an unusual way, which have produced a strong feeling that the gentlemen who write so frequently to the medical papers about this phase of professional conduct are generally men of this sort of stamp—men who want other men to do their work without paying them, men who impose on their brethren. I happen to know personally a medical man in the provinces who some years ago led a pretty controversy on this matter in the pages of a medical journal; and I can testify that he was of a most cantankerous spirit, fully alive to his own rights, and very, very unmindful of the rights of others. It will be instructive to mention two or three facts which have occurred to myself in the course of a long professional life. A medical brother met me in the street, and said: "Will you have the kindness to do my night-work for a fortnight, and one or two cases in the day—Dr. —— will take the rest,—as I am going for two weeks' holiday?" I assented. I had never requested this gentleman to do anything for me—in fact, I had never visited his house. I had a great deal to do, and some expensive medicines to supply from my own surgery. When he came home he wrote a note (in answer to mine detailing all that had been done), thanking me; but I found no cheque in the letter, nor has he ever done anything in return for me. I suppose this is medical etiquette! Not long after this another professional brother began, when he was out or engaged in pleasure or professionally, to send his midwifery cases to me, till I had in self-defence to refuse to do so any more, and send his patients away in a forcible manner. I suppose I was guilty in thus acting of want of etiquette! I can only say that had I acted differently I should well have deserved the name of "Thomas Greenhorn" or "John Simple." I will relate only one more out of many that have occurred to me. A brother practitioner whom I knew for many years, and during which time I attended for, or consulted with, or made post-mortem examinations of an important medico-legal character with, for about altogether sixty times, was asked once, and once only, to attend a case for me. He did so; and when I next saw him he, in a very hesitating, peculiar manner, told me he "thought I had a substitute." I need not say that I did not help my friend again. I suppose I was here guilty of want of medical etiquette! Many times have I lost rest at night in seeing cases for my medical brethren and receiving nothing in return; for when I have sought assistance myself I have invariably found that those most exacting in asking for help were the least anxious to return it, or anything else.

Now, I have never written on this so-called medical etiquette at all before, nor am I aware that anyone has ever accused me of the want of it. On the contrary, I feel that my professional brethren and myself are in perfect harmony; still, a long series of similar instances has convinced me that, as in most other conditions of life, there are two distinct parties in the profession—the foolish ones, who are always trying to benefit their brethren and who get imposed upon, and the knavish ones, who are always trying to exact and secure for themselves at others' expense gratuitous service. And these latter in our profession are the ones who generally fill our medical papers with long letters on the decline of medical etiquette. I know full well from much converse with my medical brethren that medical etiquette as it used to be considered is dead. It is a one-sided business altogether; and they who talk most about it and in its favour are those who are obeying their own selfish, sordid instincts by trying to make unpaid assistants of all such of their medical brethren as are foolish enough to become entangled in the cleverly contrived webs which these crafty ones are so gifted in spinning—and they name these webs "medical etiquette."

I am, Sirs, your obedient servant,

March, 1887. M.D.

*** We do not take the desponding view of medical etiquette which our correspondent does; but think it right to allow him to state his experience.—ED. L.

ADVERTISEMENT AND CHEAP MEDICINES BY A FELLOW OF A COLLEGE.

A CIRCULAR is before us, issued by a gentleman holding a F.R.C.S. and L.A.C., offering advice and medicines at very low rates, to all and sundry. Surely, a Fellow of a College should set his fellow practitioners a better example, and convey to the public a higher idea of the nature and value of the medical calling.

Cynic.—The best course for other practitioners to take in the first instance would be to make a respectful, but strong and unanimous, representation to the medical officer of health to the effect that such a line of practice on his part was disappointing and undignified. It would not be right to withhold information from him in his sanitary capacity.

M.B., C.M. (Aberdeen) need not hurry to register, as he will be able to do so at any convenient time.

J. B. should consult his medical adviser.

MR. H. A. ALLBUTT AND THE ROYAL COLLEGE OF PHYSICIANS, EDINBURGH.

To the Editors of THE LANCET.

SIRS,—As you are aware, the Fellows of the Royal College of Physicians of Edinburgh have threatened to deprive me of the membership and licence of the College for "having published and exposed for sale [so this indictment is worded] an indecent book, titled, 'The Wife's Handbook.'" The case comes on for hearing in May. As this action against me is causing much comment both for and against me in medical circles, I would ask you in all fairness to allow me to state that I have a full answer to every charge, both legal and moral. As, however, it is not for me to divulge my line of defence before action, I simply remark that I feel confident of a triumphant issue out of the ordeal. I enclose the Petition of the Council of the Malthusian League of London, forwarded to every Fellow and Member on the College roll, and I would ask you to publish it at the end of my letter. I feel sure a liberal journal like THE LANCET will give fair play to a member of the profession placed in such a position as myself.—I am, Sirs, yours truly,

HENRY ARTHUR ALLBUTT, M.R.C.P.E., L.S.A. Lond.

Leeds, March 26th, 1887.

*** We insert the above letter, but at the same time we feel bound to express our opinion that the book mentioned is one that should not be open to indiscriminate circulation.—ED. L.

Somerset.—Our correspondent has no claim against the widow if he attended the husband as a pauper under a parochial order from a relieving officer.

Mr. Laraton (Paris).—We cannot exchange.

WILL *Spes*, who wrote to us last week, kindly forward his address.

MEDICAL EDUCATION.

To the Editors of THE LANCET.

SIRS,—I have read in your report of the last meeting of the Medical Council that the subject of medical education has been referred to a committee, and I therefore hope that at last the authorities are beginning to see that a practitioner whose whole time of study has been spent at a medical school is not fitted for the immediate discharge of the responsible duties of general practice. I began my professional education as a pupil of a general practitioner who was also surgeon to a large provincial hospital, and thus, besides hospital practice, saw cases of small-pox, scarlet and typhoid fevers, measles, &c.; thoroughly learnt dispensing and medical bookkeeping, and the hundred and one things appertaining to general practice, which it is impossible to do at a medical school. Not long after being in practice I was asked to see "an interesting case of skin disease," which I had no difficulty in recognising as a case of "variola," but which had been unrecognised by the medical man in attendance, who was a "schoolman," and had never seen a case of small-pox. By the present regulations of the English Colleges all the valuable practice and teaching of country hospitals, &c., are lost to the present generation of students, and the question remains how long will the Medical Council allow the registration of imperfectly educated medical men to continue, or will they have the courage to require that students shall have at least spent one year as pupil of a practitioner holding appointments which afford the required amount of practical knowledge.

I am, Sirs, yours faithfully,

March 27th, 1887. M.R.C.S. ENG.

PARCEL-POST BOXES FOR MEDICINES.

To the Editors of THE LANCET.

SIRS,—I should be glad to know what has been the experience of others of your readers with regard to sending medicines by post in those boxes which are advertised in the medical newspapers and sold by the wholesale chemists as safe and suitable for the purpose. Those I use are made of stout cardboard, with fluted paper covering for the bottle; but several of those which I have sent away have been returned, with the bottle completely smashed and the contents of course lost. The stamps are placed on a side tag put there for the purpose.

I am, Sirs, yours faithfully,

March 23rd, 1887. F.R.C.S.E.

BREAD-MAKING.

To the Editors of THE LANCET.

SIRS,—In answer to the letter of Mr. Robert Jones in your last issue I may state that I have frequently made bread by the method named. I am not aware, however, of any pamphlet on the subject, and fancy your correspondent must refer to one published by the Aerated Bread Company, who, I believe, still sell the bread in London. But this is prepared in a different way—viz., by forcing in the carbonic acid gas by machinery during the mixing of the dough. I believe the method required is to be found in the earlier editions of Pereira's Materia Medica, whence I copied it, as follows: "Unfermented bread.—Flour, 1 lb.; bicarbonate of soda, gr. xl.; cold water, half a pint, or as much as may be sufficient; muriatic acid, fifty drops; powdered white sugar, one teaspoonful. Intimately mix the soda and the sugar with the flour in a large basin by means of a wooden spoon. Then gradually add the water with which the acid has been previously mixed, constantly stirring, so as to form an intimate mixture very speedily. Divide into two loaves, and immediately put them into a quick oven."

I remain, Sirs, yours truly,

Plymouth, March 26th, 1887. H.

To the Editors of THE LANCET.

SIRS,—In reply to Mr. Robert Jones, allow me to say that unfermented bread is best made by taking 120 grains of bicarbonate of soda for every pound of flour, 120 minims of pure muriatic acid, and a little less than a pint of water. Let the water and acid be intimately mixed, and the soda be sifted into it and well mixed with the flour or meal; then gradually add the acidified water to the consistency of light dough, bake in a brisk oven for about an hour. I am, Sirs, yours faithfully,

Sandy, Beds, March 26th, 1887. H. C. STROVER.

L. E. A. is always liable to the consequences of having made a false declaration. His best course is candidly to state the facts to the body aggrieved, and throw himself on its kindness.

Mr. J. C. Gibson.—The Charities Register and Digest, published by Longmans, or our own advertising columns, will afford the information desired.

X. Y. Z.—The Riddell fund was closed on Jan. 19th of the present year. The sum raised altogether was, we believe, a little over £60.

Mr. J. A. Jones (Tir Caradoc).—The cases had, perhaps, better go together.

NIGHTMARE.

To the Editors of THE LANCET.

SIRS,—Allow me to suggest that "M.D." should take half a grain of the red iodide of mercury in pill night and morning for six or seven days. He should take a very light supper, avoid all stimulants, and take such measures as will prevent him lying on his back whilst asleep. The cause of nightmare I believe to be congestion of the coördinating centre, the cerebellum. In your correspondent's case possibly this is secondary to his liver's inaction.

I am, Sirs, your obedient servant,

March, 1887. MEDICUS.

Dr. Steven.—No copy of the Japanese Pharmacopœia has reached us, and we have no information at present beyond what appeared in the paragraph alluded to.

Sanitarian will find a *résumé* of the course of the cholera epidemic in 1886 in our issue of Jan. 15th last.

Mr. E. Colson.—The report appeared in THE LANCET of March 26th.

Resident Physician to a Kursaal has not enclosed his card.

Croonian Lectures
ON
THE PULSE.

Delivered at the Royal College of Physicians of London, March, 1887.

BY W. H. BROADBENT, M.D., F.R.C.P.,
PHYSICIAN TO ST. MARY'S HOSPITAL, CONSULTING PHYSICIAN TO THE LONDON FEVER HOSPITAL, AND PRESIDENT OF THE CLINICAL SOCIETY.

LECTURE III.

MR. PRESIDENT AND GENTLEMEN,—Examples of the effect upon the pulse of diseases of the nervous system might be multiplied indefinitely, but I propose to ask your attention to the converse of this—namely, to effects produced on the brain by abnormal conditions of the circulation.

The nutrition of the brain, as of all parts of the body, is dependent upon the supply of an adequate amount of healthy blood, but the functional activity and efficiency of the brain is even more dependent upon the blood-supply than its nutrition, and is influenced by it to an extraordinary degree, so that blood which would maintain the structural integrity of the brain might be altogether unfit to minister to its functions. The presence of alcohol in the blood, for example, does not interfere with the nutrition of the nerve centres, but it deranges their action, and poisons generated in the system or retained excretory matters may have a similar effect. The liberation of nerve force has been represented as an explosive action, and this implies the presence in the nerve cells of a substance ready, on the application of the proper stimulus, to combine instantly with the oxygen brought by the blood. The formation of such material, its maintenance at a given state of chemical tension, so to speak, which differs in the different centres, in the cortex, in the central ganglia, and in the medulla and cord, is not paralleled by any other nutritive operation. There is, moreover, the further requirement of a due supply of oxygen.

An illustration of the relation between cerebral functions and the circulation is seen in the anæmia of the cortex of the hemispheres during sleep. This bloodlessness is essential to sleep, and, if it can be induced, sleep follows. It is not clear, however, whether it is primarily the shutting off of the blood which determines and compels sleep, or the exhaustion of the nerve cells and the periodic cessation of activity organised in the experience of the nervous system by the succession of day and night, which disposes to sleep, and provides for it by causing the cortical arterioles to contract so as to produce the anæmia. Sleeplessness is extremely common, and may be due to a great variety of causes—to excitement during the day or in the evening, to grief or anxiety, to exhaustion or overwork, especially work of an intellectual kind carried on far into the night, to late meals, errors in diet, indigestion and flatulence, or other functional derangements, and to tea or coffee. On the recognition and removal or avoidance of any such disturbing influences the sleeplessness will disappear. We are frequently called upon, however, to relieve habitual sleeplessness which cannot be referred to any of the above causes, and in many instances it is associated with abnormal conditions of the circulation. Not to speak of heart disease, all forms of which are prone to disturb or interfere with sleep, or of palpitation, which is apt to come on at night, there are two distinct conditions of the circulation to which sleeplessness is very often due. One is the state of high tension, absolute or virtual. There may be little beyond the sleeplessness of which the patient complains, or the loss of sleep may merely be one of a long train of symptoms—depression, apprehension, loss of memory, want of energy, and the like. The artery at the wrist may be large or small, but it is full between the beats, and can be rolled under the finger; the pulse may be long and gradual, or somewhat abrupt in its beat, and ending suddenly, according to the condition of the heart. It appears to me probable that the cause of the sleeplessness in the class of cases under consideration is the inability of the arterioles of the cerebral cortex to overcome the excessive blood-pressure within them, and shut off the blood so as to induce the anæmia requisite for sleep. In common with the peripheral arteries generally, their muscular walls are all day putting forth an abnormal amount of contractile force, and at night are unequal to the further task of exercising sufficient additional contraction to narrow the channels to sleeping point. In such cases sleep is often at once procured by reducing the general arterial tension, and a mild mercurial aperient is the most efficient hypnotic. The cases are numbered by scores in which I have found this line of treatment efficacious in habitual sleeplessness, many patients having been rendered independent of sedative draughts to which they had been driven. At first it is not unusual for the patient to suppose that a new and powerful opiate has been given, and the good effects do not wear out by repetition. It is not by unloading the bowel that the aperient acts; it has often to be given to induce sleep when the bowels are acting regularly and freely; and it is to be remarked that it is within an hour or two of the pill having been taken, and many hours before an evacuation results, that the patient sleeps. The general intra-vascular pressure being lowered, the cortical arterioles are no longer resisted by the pressure within them, and they can respond to the call for exclusion of the blood from the hemispheres. The desired effect may often be attained by other means—by a hot bath, by the sitz bath and wet bandages employed in hydropathic establishments, by standing in cold water and then rubbing the feet well with a rough towel, and by a variety of other measures, which either relax the cutaneous vessels generally, and so lower the arterial tension, or set up a local hyperæmia which diverts the blood from the head. A method of courting sleep, which I have known to be adopted by subjects of high arterial tension, is to lie with the back of the neck on a hot-water bottle. Sometimes, however, the object is defeated by some collateral effect—for example, as when a hot bath sets the heart beating violently, and, when successful, such measures often having the defect of dealing with the effect and not removing the cause.

An opposite state of the circulation, extremely low tension, may be the cause of sleeplessness. It is more common after middle life and in men of sedentary occupation, and may be traceable to overwork or anxiety, or simply to close attention to business and neglect of holiday. It is not often that there is excess in eating or drinking; more frequently the patient is distinctly abstemious. Without apparent cause he begins to lose his sleep at night. In the day-time, however, he is disposed to sleep, and, not unfrequently, unless engaged in actual work, he drops asleep at any moment; not only after dinner, when sleep in such cases is irresistible, but when reading his newspaper in the morning after breakfast. Not unnaturally, it is supposed that the after-dinner nap spoils the night's rest, or that the bad night causes the drowsiness during the day, but attempts to rectify this state of things by preventing sleep after dinner and similar measures fail. The sufferer may try to secure a good night by going to bed soon after dinner, but at this time, as at the usual hour for retiring, as soon as he lies down he is wide awake, and so remains. After a time it will be discovered that it is position which induces or prevents sleep. In the sitting posture sleep is almost irresistible, in the recumbent position almost impossible. The patient will sometimes get out of bed in the night and sleep in his chair, as we see sufferers from advanced heart disease. Under such circumstances I have found the circulation unstable; the pulse, during the same interview, at one time short and weak, and at another presenting the characters of virtual tension—that is, full between the beats, but compressible, sudden and not sustained; and the power of the heart low. There is a want of tone in the muscular tissues of the arterioles and a want of driving power in the heart, and the distribution of the blood thus becomes unduly influenced by gravity. In the sitting position, when the heart is not stimulated by exercise, nor afflux of blood to the convolutions determined by mental work, the blood is not lifted to the height of the brain with sufficient energy, the contractile tendency of the cortical arteries is not opposed by intra-vascular pressure, and sleep-producing anæmia of the hemispheres results. On the other hand, this same want of tone in the arterioles allows them to be distended by the increased pressure of the blood within them which attends the horizontal position. In such cases change of air will often put an end to the sleeplessness at once, and

Digitized by Google

the appropriate remedies are vascular tonics—iron, acids, strychnine, and digitalis.

Convulsions and the pulse.—Conditions of the circulation indicated by the pulse are unquestionably among the causes of convulsions. The brain responds by convulsions to a great variety of disturbing influences: to direct irritation of the cortex, as has been demonstrated by experiment, and is illustrated by spiculæ of bone, tumours, meningeal hæmorrhage, &c.; to irritation of lower centres and tracts, such as the cerebellum and its superior peduncles, or in the interpeduncular space, and to reflex irritation of the most varied kind; to poisons of different kinds, but especially to the poisons of specific fevers, such as small-pox, scarlatina, or measles.

With regard to such causes of convulsions as concern us from their relation with the pulse, experiment has shown that convulsions may attend exactly opposite states of the circulation. The final phenomena of death from rapid hæmorrhage when the cerebral vessels are empty and the pressure (presumably at a minimum are convulsions, and convulsions occur in death by asphyxia when the blood-pressure is high. These extremes probably meet in the production of stasis of the cerebral circulation, and it seems to me that we have clinical illustrations of convulsions produced by unduly high arterial tension on the one hand and by excessively low arterial pressure on the other.

The cranium being a closed cavity, the total volume of its contents, brain-structures, blood, and cerebro-spinal fluid, must be a constant quantity. The effusion of liquid into the ventricles or meninges often found after death shows that some sort of compression and shrinkage of the brain substance is possible, but whether this is at the expense of the blood in its capillaries, or of fluid in the perivascular spaces, or of interstitial fluid, cannot be stated definitely; since, however, there may be greater appearance of vascularity in the sulci and white matter at the same time, it cannot be by exclusion of blood that the intra-ventricular or sub-arachnoid fluid makes room for itself. But whatever may be the way in which the brain-substance accommodates itself to effused fluid, it is not to be supposed that it is compressed into smaller compass at each pulsation of its vessels. This being so, either the blood must escape by the veins exactly in the same amount and at the same time as it enters by the arteries, and therefore more or less in a pulsatile manner, or there must be some shifting to and fro of cerebro-spinal fluid between the cranial and spinal cavities—that is, the expulsion of a certain amount of fluid from the cranium into the spinal canal with each arterial pulsation, and a gradual reflux in the interval. But the spinal canal is also a closed cavity, and, although its walls, being only ligamentous between the vertebræ, are not so rigid as the bones of the skull, there is no provision for variations in its capacity, while the arteries of the cord and its meninges will be distended at the same moment as those of the brain, which would tend to resist the passage of fluid from the cranial to the spinal cavity. The to-and-fro movement of cerebro-spinal fluid, then, which has been postulated as an easy explanation of some of the difficulties with regard to the cerebral circulation, cannot be admitted, and it must be the case that, exactly as the blood enters the cranium by the carotids and vertebral arteries, it leaves it by the internal jugular veins. The movement of blood in the internal jugulars has, in fact, been found to be pulsatile. I have pointed out in my first lecture that neither the expansion of the arteries nor the onward movement of the blood is as great as is usually supposed, and there is a provision both in the carotids and vertebrals for moderating the current (which is present in a still more marked degree in animals which feed on the ground); but, with all this, the intra-cranial circulation is carried on under peculiar difficulties, and any interference with the general circulation may tell with special influence upon it.

In the eye the circulation is under much the same conditions as in the brain in so far as the effects of high intra-vascular pressure are concerned—the sclerotic being [illegible]; and the changes which are known to take [illegible] in renal disease have more than a mere [illegible] or clinical interest. They throw light on changes [illegible] and study and investigation in this [illegible] much needed. We have retinal as we have [illegible] all is possible, again, that there are [illegible] like in kind to those of the choked [illegible], if different in degree, and which may be changes in the [illegible] substance [illegible] spots in the [illegible]. All these [illegible] to pressure effects rather than to blood deterioration. Glaucoma, which in my small experience has always been associated with high pulse tension, and which I believe to be an effect of intra-vascular pressure, may also have its analogue in the cranium.

Be this as it may, there cannot be any doubt that the intra-cranial pressure varies with each heart beat and with all variations of the blood-pressure in the arteries or veins. The brain would pulsate if it could, and does pulsate whenever a part of the cranial vault is absent or yielding. The fontanelle of an infant beats with the pulse, rises and falls with the respiratory movements, is tense and prominent when the child cries, hollow when it is asleep, is full and firm when the child is well, depressed when it is weakened, say by diarrhœa; and the same fluctuations can be seen at a trephine opening in the adult skull. The same pressure fluctuations which give rise to the pulsation and varying tension of the fontanelle will, in a greater or less degree, tend to compress the cortex of the hemispheres against the vault of the cranium; and it is conceivable that the compression might be such as to interfere with the free passage of blood through the pia mater of the convolutions, or to flatten more or less the veins which run on the surface of the hemispheres to the longitudinal sinus—it might, indeed, arrest momentarily the cortical circulation. Blood stasis in this situation, from pressure against the cranial vault, must occur when the convolutions are flattened by effusion into the ventricles in tubercular meningitis, and it is not unreasonable to suppose that the convulsions and loss of consciousness which mark the final stage of this disease coincide with this event. But there are not wanting evidences of the production of momentary arrest of the cerebral circulation by comparatively slight temporary causes. Some years since I met, at a scientific congress, a distinguished French surgeon who at the age of fifty-five or sixty was suffering from whooping-cough, and at every paroxysm dropped down unconscious; and I have met with a case in which for many years the patient, who was the subject of chronic bronchitis, fell down with momentary loss of consciousness and slight convulsion whenever he coughed, and this too quickly for the production of cyanosis. In these cases the obstruction would take effect by backward pressure through the jugulars. Short of any such result as loss of consciousness, it is not uncommon for the respiratory concussion attending the act of coughing to be felt as severe pain in the head.

A gradual encroachment on the capacity of the cranial cavity would exert a very similar influence on the cortical circulation by pressure from without to that which I am assuming might be the result of pressure from within, and the effects of such an occurrence are exemplified in the following case seen with Mr. Brend of Kensington. The patient, a lady aged about thirty-six, had enjoyed good health all her life, and had had children, when she began to be subject to fits. She was seen by various physicians, and different opinions were given as to the character of the attacks; for the most part they were considered to be hysterical. She was subject to headache and confusion of thought, but not more so than is common; there was no vomiting. When I was consulted she looked well, was stout, and had a good colour, and was discharging all her family and social duties, though with effort. Just as she had taken off her dress to facilitate an examination of the chest, an attack came on which we were so fortunate as to witness. She turned pale and lost consciousness, there was a slight quiver of the muscles of the face and movements of the arms, but the most striking fact was a complete arrest of the heart for a sufficient time to cause us serious anxiety. This prevented us from adopting the opinion previously given, that the fits were of no importance, and our prognosis was soon afterwards verified by the patient's death in one of the attacks. The only morbid appearance found was an extraordinary thickening of the frontal bone, which was as dense as ivory, and more than half an inch thick at the lower part, gradually thinning towards the coronal suture. The inner surface was smooth, and the dura mater little changed.

The following are examples of convulsions associated with high pulse tension.

A medical friend called on me one morning [illegible] at the bidding of his wife, as he told me laughingly. He said he had had some sort of fainting attack, but that he was perfectly well. His forehead, however, was covered with minute ecchymoses, and it was obvious [illegible] had

Digitized by Google

had severe convulsions. He was forty-two years of age, had lived freely and carelessly, but was not intemperate; there was a doubtful history of syphilis, and twelve months previously he had had a severe fall on his head. He had very high tension of the pulse. I was summoned to him early next morning, and found that he had gone from one convulsion into another for the greater part of the night, of so severe a character that artificial respiration was required at the end of each attack. I had no hesitation in attributing the convulsions, the first and last he had ever had, to the state of the circulation, and the patient was bled to about thirty ounces. He had the last convulsion as the blood was flowing, made a rapid and complete recovery, and has had no attack since.

In another very similar case, also that of a medical man, aged about fifty, seen three years since, I did not see the convulsions, which had been very violent, but the assurance I felt justified in giving, from the history and from the state of the pulse, that no recurrence need be apprehended if the tension were reduced by appropriate diet and treatment, has been verified up to the present time, and the patient has improved greatly in general health.

A third case, that of a lady, aged at that time forty-nine, came under my observation in May, 1878. She was stout, over-fed, and had marked tension of the pulse, which appeared to be taking effect on the left ventricle. She was said to have albuminuria, but I found no albumen in the urine, and the specific gravity was normal. I was consulted on account of severe and repeated convulsive attacks of an epileptic character, which came on two or three times a week, sometimes in series of six or seven. The convulsions speedily ceased under treatment by saline aperients, which lowered the vascular tension, and she remained free from them until 1885, when she had cerebral hæmorrhage and hemiplegia, and she died late in 1886 from another attack, attended with convulsions.

In December, 1885, a gentleman aged sixty-five, working hard as a teacher of music, consulted me on account of convulsions, which had occurred in the previous July before breakfast, and on December 1st after dinner. On the latter occasion there had been sudden loss of consciousness, and a fall, in which a cut on the head had been sustained. He looked and felt well, had a fresh colour, the appetite was good and the bowels regular, and he slept well. The urine was copious, had a specific gravity of 1015, and contained neither albumen nor sugar. The pulse was tense, but short; the first sound of the heart short, the aortic second accentuated. The condition of the circulation was that of virtual tension. A mild blue and colocynth pill was ordered to be taken once a week, and arsenic and nux vomica prescribed as a tonic. In March, while stooping after a heavy meal, he fell forwards and was unconscious for a few seconds, and this is the only attack he has had.

Other illustrations might be given, but I will only refer to one more which I related in my address as president of the medical section of the Brighton meeting of the British Medical Association. The patient, aged thirty-seven, came under my observation in November and December, 1885, suffering from headache and oppression, and was found to have an unusual degree of arterial tension; and shortly afterwards I was called to him in consultation with Dr. Wilbe, when he was almost unconscious, overwhelmed apparently by a sense of pressure in the head and exhibiting violent synchronous contractions of the pectoral and abdominal muscles. The pressure in the arteries was extreme, and the incompressibility of the pulse surpassed anything in my experience. The patient was bled with good effect, but repeated free calomel purging was needed to bring down the tension and complete the recovery. There was an early stage of contracting kidney in this case, but no such change as to give rise to uræmia.

The convulsions which sometimes occur months or years after an attack of hemiplegia have, in my experience, always been associated with high tension, and have often been prevented from recurring by treatment directed against this. In a brain damaged by hæmorrhage, which has left a cicatrix, the circulation is more easily deranged to a point attended with symptoms than before. It may be considered as proved that, in some way, such a modification of the cerebral circulation may be produced by high arterial tension as is capable of giving rise to convulsions; and, as I have already said, it is, in my opinion, through the intervention of high arterial tension that uræmic convulsions are brought about. There may be extreme uræmic intoxication, ending fatally by coma, without convulsions; urea, the ammoniacal products of its decomposition and the forms of nitrogenised waste, which may be supposed to accumulate in the blood in renal disease, do not excite convulsions when injected into the blood. These facts seem to show that it is not simply and directly by the presence of renal impurities in the blood that the convulsions are excited. On the other hand, there are the facts that uræmic convulsions are most common in that form of kidney disease in which high arterial tension is most marked—the contracted granular form,—and that they do not occur in the absence of, at any rate, a certain degree of tension. But the consideration which carries perhaps the greatest weight is the remarkable effect of bloodletting in uræmic convulsions. The status epilepticus is cut short, the coma abbreviated, and associated symptoms relieved. These effects, which are remarkably constant, cannot be from elimination of toxic matter; the blood left in the vessels will be both more watery and more impure from resorption of liquid from the tissues. They can scarcely have any other cause than diminution of the volume of blood and lowered pressure in the vessels.

In acute renal dropsy with convulsions a venesection may not only arrest the convulsion, but may exercise a favourable influence on the disease, and in chronic Bright's disease, nearing a fatal termination, bleeding may prolong life and change altogether the mode of dying from convulsions and coma to a quiet asthenia. Illustrations of the association of convulsions with low arterial tension are less common, but I have seen in a child of twelve, belonging to a family in which the pulse tension is low, and who has the family pulse, a momentary convulsion during vaccination. There was no nervousness or fear, but, on the contrary, the operation was regarded with interest. The child, however, dropped as if shot, with a slight general convulsion, and then immediately got up again, looking very much astonished, but not otherwise affected. In another low-tension individual, a young man of remarkable courage, the application of a few leeches to the ankle, which had been injured rather severely, was followed by syncope, emergence from which was attended with brief but sharp general convulsions.

In the following case, seen first with Dr. Godson, Mr. White, and Dr. Kane, and later with the latter gentleman, the association of convulsions with an extremely low pulse tension and their dependence upon a feeble circulation seemed to be very clear. The patient, a lady aged about twenty-six, florid and healthy, was confined on Aug. 3rd, 1886. Second confinement; previous one normal. Three weeks before labour she had phlebitis of the right saphena vein, with great pain, some pyrexia, but little œdema; it terminated favourably in about fourteen days, leaving a hardened vein. Labour natural. Some membranes were retained, but gave no signs of their presence till the seventh day, when the discharge became offensive. There was pain over the abdomen and slight rise of temperature. The uterus was washed out with Condy's fluid, and the next morning the pain had disappeared. A rigor followed the injection of the uterus, and the temperature rose to 105° F. The discharge continuing fetid, injections were repeated, and the retained membranes came away. An offensive discharge persisted for a day or two, after which the lochia became sweet and normal. The milk stopped fourteen days after labour. From the first rigor dates the commencement of the high temperature. Daily it rose to 104°, 105°, and even 106°: but, at the same time, it invariably fell to normal sometime in every twenty-four hours. There was no regularity in the periods of high and low temperature; some days it would rise rapidly to the maximum, and after an hour would fall as rapidly; on other days it would remain about normal most of the day. The pulse, always weak, was most rapid and irregular, sometimes quite uncountable. Terrible rigors occurred almost daily, generally commencing when the temperature was low, and invariably followed by rapid rise of temperature. The patient suffered comparatively little from the high temperature, had no delirium, and seemed to be more comfortable than when the temperature was normal, though the weather at the time was extremely hot. On the seventeenth day after labour, phlebitis occurred in the right saphena. This phlebitis continued to give trouble, on and off, for another ten days, and there was considerable swelling of the ankle. The rigor and temperature continuing unchanged, in spite of all remedies, it was decided, on Sept. 15th, forty-three days after labour, to remove her to another house.

Digitized by Google

There was the more pressing reason for this, as an expert had decided that sewer gas entered the house. She bore the move well, and for a time seemed to improve. She had some slight shiverings, but no more rigors. For several days the temperature never rose above 102°. She had numerous small boils. On the sixth day after the move (Sept. 21st) her temperature rose suddenly to 106°, fell again to normal, and in the evening rose again to 104°. She did not seem worse in any other way. About 10 P.M. I was suddenly summoned, the messenger saying she was dying. I found her sitting up in bed, with very flushed face and widely dilated pupils; she appeared quite unconscious, with gasping respiration, and very rapid and tumultuous action of the heart. I diagnosed cardiac embolism. Soon after my arrival she fell back and passed into a terrible convulsion, face turned to the left, arm drawn up, and legs extended and rigid. This lasted some minutes, and was followed in half an hour by a second, and again, before morning, by a third. After the convulsions, the left arm seemed paralysed, but this passed off before morning. She was very prostrate, and moaned a great deal, and if moved screamed out and applied her hand to the right side of her head. No inequality of pupils; passed urine and motions in the bed. Mental condition very excited: at first aphasic and unintelligible; afterwards noisy—singing, crying, and praying. After this she sank into a very depressed condition, with constant tendency to failure of the heart. The slightest attempt to sit up caused giddiness and slight convulsion. She had to be constantly watched, and at times even artificial respiration had to be resorted to. Face sunk, and whole aspect of impending death. Temperature 104°; pulse utterly uncountable. Such was her state on Sept. 26th, fifty-four days after labour. The case was considered hopeless, but it was determined to persevere steadily with large doses of tincture of muriate of iron and digitalis in gradually increasing doses. The result was highly satisfactory. The patient rallied and steadily progressed from this date. Quantities of small boils appeared, and gave her much pain. Delirium continued for some days, and she had some delusions. The slightest attempt to sit up brought on a slight convulsion. The temperature never again rose above 102°, and in a very few days fell to normal, and remained at that. Ten days after the first convulsion she had another severe one, followed by a return of the mental disturbance. She was free from attacks, except slight ones, for about a fortnight, when she had another severe attack, then an interval of three weeks, and a series of terribly severe ones lasting six hours. It being thought that the convulsions might be due to an attempt to restore the catamenia, attention was turned in that direction, and after some time the menstrual flow was established, ushered in by several slight convulsions. All this time her progress to health had been continuous, with the exception of a slight pneumonic attack, with some fever and cough, which disappeared after she had coughed up a patch of deep rusty mucus. She had numerous slight convulsive attacks, generally on waking up from sleep; but they left no after-effects, and she steadily improved until Jan. 26th, six months from the commencement of her illness, when she was well enough to be moved to Hastings, and underwent the journey without any fatigue or after bad result. She is now in capital health; but her pulse has a tendency to become irregular, and she has occasional attacks of threatened convulsions. The above account has been supplied to me by Dr. Kane. I first saw the case on October 9th, when the pyrexia had been overcome and the convulsions had set in, and had no hesitation in referring them to the exhausted state of the heart, which could not be felt, and could scarcely be heard, while the pulse was all but imperceptible. The fact that the patient could scarcely be raised in bed without bringing on an attack of convulsions was of decisive significance.

I have at present under observation a gentleman, aged fifty-two, who consulted me on account of shortness of breath on going upstairs, and especially on going up the steps from the railway station. He had become so nervous on the subject that his heart began to palpitate and his breath to go before he came to the foot of the stairs. He had palpitation also occasionally at night. He looks the picture of health and younger than his years; is stout and of rather high colour; eats and sleeps well; and has a regular action of the bowels. He rides a tricycle, and has much fresh air and exercise. The pulse is frequent, 90 to 108, small, short, and extremely compressible. The heart is partially covered by lung, does not appear to be enlarged, and gives no impulse or apex beat; the sounds are short and approximated, the second following the first too quickly. The first sound is audible, not only at the apex and right second space, but also in the neck, where both sounds are remarkably distinct. He spoke of having had a fainting attack, and when this was inquired into it was described as having occurred as follows. It was in August, and he had had a tricycle ride, had washed and changed, when he thought he would like a glass of beer, which he had not tasted for years. Shortly afterwards he felt a peculiar tingling in his feet and had just time to lie down when he lost consciousness, and did not come to himself for forty minutes or more. This could not have been a syncopal attack, and, whether convulsions occurred or not, was epileptoid. It was further learnt on inquiry that he had had several similar attacks within the last few years, always beginning with the tingling sensation in the feet, and attended with complete loss of consciousness, lasting on an average twenty minutes. He had had no fits of any kind as a boy, or until the occurrence of those referred to.

I am not without hope that a careful study of the pulse, and of conditions of the circulation made known through it, may be of service in furnishing indications for the treatment of epilepsy. It is certainly attended with interest, and I think it throws light on different forms of epilepsy, and serves as a guide in prognosis. Epilepsy is apparently the result of instability in the highest nerve centres, the cells of the cerebral cortex permitting of an indiscriminate general or partial discharge upon lower centres of nerve force, which normally ought to be set free, only in definite degree and in well-defined direction, in response to given stimuli. Such instability is obviously a nutritional defect, which may be due to the inherent want of constructive energy in the nerve cells themselves, or may be the result of blood which cannot furnish the proper pabulum, or of an inadequate supply of blood. Even in the case first supposed, a regular and ample supply of blood, under sufficient pressure to cause a due exudation of nutrient material and of proper composition, will be important, while in the other conditions supposed they will be remedial. But, given more or less of instability, this does not of itself start the convulsive explosion; some exciting cause must be applied. At one time this was supposed to be arterial spasm in certain convolutional areas; but this hypothesis, which never seemed to me to be tenable, has gone out of fashion. There are, however, facts which seem to show that circulatory conditions have much influence in determining the occurrence of attack: for example, the great frequency with which fits come on in the night, sometimes on first going off to sleep, when the horizontal position and the anæmia of the cortex attending sleep produce great changes in the intracranial circulation; or more frequently towards morning, when the general circulation has slackened down, as it does during sleep. Another favourite time for attacks is soon after rising in the morning, when the general circulation has slackened, and circulatory changes of a reverse kind take place.

It is not my intention to discuss the questions which might be raised on the subject here alluded to, but I desire to call attention to a provisional conclusion to which I have been led by my own limited observation. This is, that in essential epilepsy—the epilepsy which comes on during adolescence, the epilepsy met with in neurotic families, and in which the nerve cells may fairly be assumed to be inherently unstable—the arterial tension is low and variable or fluctuating. I am unable to affirm that when the attacks are suspended, as they may be for months, the pulse tension is improved, but it is worthy of remark that pregnancy is not unfrequently attended with immunity from fits, and, as is well known, one effect of this condition is high tension in the pulse. On the other hand, when the pulse tension is decidedly and constantly above the average, it has seemed to me that the epilepsy has been amenable to treatment. Senile epilepsy is, according to my experience, associated with high tension, and scarcely ever fails to yield to a regulated diet with a restricted amount of animal food and little stimulant, aperients and other eliminants being given, according to the requirements of the particular case. Epilepsy with high arterial tension often comes on at a later period than the epilepsy, which has its source in a radical weakness of the nervous system, and, in most of the cases I have met with, the first fit has occurred after the age of twenty, and not uncommonly there have

Digitized by Google

been peculiarities, such as a number of attacks close together, with long but irregular intervals, or some well-marked exciting cause. The fits may, however, date from the usual age at which epilepsy sets in. Many years since, a surgeon-major in the army brought his son to me on account of epileptic attacks, which had compelled him to leave the navy. He was a fine, strong, healthy-looking lad, and had a large pulse not easily compressed. Under treatment the fits, which had been so frequent, ceased to come on. He studied for and got into Sandhurst, obtained a commission in an infantry regiment, and has since served through the Afghan campaign. So far as I know, he has only had two attacks since he entered the army: one in Afghanistan, when, together with trying work, he had bad food and water; and another in Ireland, after great fatigue and a bout of dissipation.

I have several times seen violent maniacal delirium associated in such a way with convulsions as to suggest that a minor degree of the disturbing influence which caused convulsions had given rise to the maniacal excitement—after bleeding, for example, for uræmic convulsions, before and after, or apparently instead of uræmic convulsions—in syphilitic disease of the brain. In the following case the connexion between the state of tension of the pulse and ungovernable excitement was recognised by several observers over a long period. The patient was under the care of Dr. Ranking at Tunbridge Wells, and Dr. Marcus Allen at Brighton, and in town under Dr. Seton and Dr. Coates, with whom I saw her weekly from March to July, 1884, and again in March, 1885. Dr. Ranking, who has kindly supplied me with the particulars, was called to her in May, 1882, when she was convalescing from a third attack of slight (left) hemiplegia. She was very nervous and apprehensive, and had dilatation of the heart, with an unstable pulse of virtual tension. During the summer she had several anginoid attacks, which were relieved at once by nitro-glycerine, and in the winter attacks of congestion of the lungs, with partial suppression of urine and albuminuria. One day in July, 1883, she became suddenly excited, with delusions, which lasted some time, but went off after one-hundredth grain of nitro-glycerine, and she slept. Later in the summer she got into an excited, unsettled, suspicious, and violent state, which persisted, together with high tension of the pulse. Once she was comatose for twenty-four hours, but recovered after nitro-glycerine, and at once became maniacal. In the winter of 1883-84 she was under the care of Dr. Marcus Allen at Brighton. It was found by observation that her mental condition was always worst when the pulse tension was high, and that the only way of keeping it down was to cut off all meat and feed the patient chiefly on milk. This was confirmed by our experience when she was brought to town. When the tension was high she was suspicious, abusive, violent, and unmanageable. When it was normal she was cheerful and tractable. Mercurial aperients were constantly needed in order to keep down the tension and regulate the bowels. Ultimately she died, in March, 1885, with symptoms of meningeal hæmorrhage.

With advancing years there comes a liability to many forms of cerebral affection. Some are examples of structural change which are clearly traceable to interference with the normal blood-supply. Such changes are local or general softening from thrombosis of individual arteries, or general obstruction to the blood-supply from atheroma, affecting all the cerebral arteries. The local arterial change is not the sole factor in the production of the lesions. A state of blood which renders it prone to coagulate or deposit fibrin will predispose to the formation of a thrombus at any point where the walls of the artery are diseased, and want of propulsive power in the heart, or other cause of languid movement in the blood, may antedate the occurrence of degenerative changes attributable to widely distributed disease in the vessels. But an impeded cerebral circulation may, in course of time, so far modify the nutrition of the brain as to give rise to functional affections without structural lesions; and this, in my opinion, is the mode of causation of some forms of insanity which come on late in life—such, for example, as senile melancholia. The term senile may have two meanings—it may designate an age, or be descriptive of a kind of change. The term senile is unobjectionable if it is meant to apply simply to the period of life at which this affection is met with, but it is often understood to mean a certain character of change, and its frequent employment to designate degeneration has led to the common idea that senile and degenerative are convertible terms. This does harm in two ways. Senile changes, if degenerative, are irreversible, and if this view is taken of dementia or melancholia, there will be no object in careful investigation of associated conditions, no other cause than senile decay will be looked for, and no individual treatment will be adopted based upon the peculiarities of different cases. Furthermore, the reproach of insanity or of neurotic tendencies may be attached to families when the derangement of the cerebral functions may be as much a result of vascular disease as cerebral hæmorrhage. A family liability to melancholia may consist in hereditary high tension of the pulse, just as a liability to apoplexy may be due to family gout. Now the complete recovery witnessed in many cases of melancholia is proof that there cannot have been any structural degeneration, and an example like the following may be worth relating.

Some two years since I was asked to see, periodically, a gentleman, aged about sixty, who had for four or five years been under the Commissioners in Lunacy on account of melancholia. He had had delusions as to conspiracies against his life, but such delusions as remained related chiefly to wilful and malicious injury inflicted upon him, and attempts to destroy him in an asylum. He spent nearly all his time in bed, scarcely ever left his room, and never went out of doors. He was well nourished, and, except that he was etiolated by his long confinement to the house, looked well; but the pulse was extremely small, soft, and short, and the action of the heart extremely weak. He had eczema, and suffered from constipation and want of appetite, and treatment was prescribed for the relief of these symptoms. His general health improved, but his mental condition remained much the same, and, in particular, the death of a son made little impression on him. In June, 1886, he suddenly shook off all his delusions, and became perfectly sane and cheerful. With this the pulse improved, but never reached an average volume or tension, and in October he remained well, and, after examination by Dr. Maudsley, was discharged from his lunacy. Unfortunately, on Feb. 24th of this year he became aphasic from thrombosis of the vessels supplying the cortical speech centre.

Pulse and melancholia.—The connexion between melancholia and its allied mental states and conditions of the circulation is more direct and decided than can be traced in epilepsy. An unbroken series of gradations can be traced from the irritability and depression of spirits, attending functional disorder of the liver, up to complete melancholia with delusions. In a case of temporary hepatic derangement, the state of the temper and spirits might be attributable to the retention in the blood of the impurities which tinge the eyes and complexion, this acting as a poison; or to some reflex influence, inhibiting cerebral functions, or deranging the cerebral circulation by setting up contraction of some of the arteries. When, however, the mental depression is more pronounced and persistent, these explanations are found not to apply; there may be, in the first instance, constipation, a furred tongue, sallow complexion, large liver, &c. But when these evidences of deranged function are removed the mental condition does not clear up. If the symptoms, therefore, are due to any somatic cause and are not the outcome of a primary cerebral affection, this cause is something more persistent than the functional derangement or reflex disturbance mentioned. This has appeared to me to be protracted arterial tension, or, if it is not itself the cause, it is at least the index of the condition of the state of system on which the mental condition depends.

The method by which high arterial tension may influence the cerebral functions may be conceived to be as follows. The resistance in the peripheral vessels calls for increased contractile force on the part of the left ventricle, and there is a response by a certain degree of hypertrophy. In the course of years, however, the resistance increases, degeneration of the capillaries and thickening of the arterioles being superadded to the original loss of due relation between blood and tissues, while the heart no longer gains in strength. With, then, the same or somewhat diminished driving power and the resistance increased, there will be a slower onward movement of the blood. The pulse may be equally strong, may even seem to be more incompressible, but the capillary circulation will be sluggish. This will be the case throughout the system, but it will not give rise to appreciable effects in most of the structures and organs; in the brain, however, as has already been said, functional activity and efficiency are absolutely dependent upon a due supply, not only of nutrient material, but also of oxygen,

Digitized by Google

and this fails when the flow through the capillaries is sluggish.

In a very large proportion of the cases of melancholia coming on late in life the evidence of persistent high tension of the pulse has been most marked, and when this has been the case it has seemed to me that persevering endeavours to diminish the peripheral resistance, and at the same time to strengthen the action of the heart, have been more successful than any other line of treatment. The object is so to relieve the heart that it may no longer be mastered by the obstruction in the general capillary circulation; there will then be a general acceleration of the flow of blood through the tissues, and by the increased supply of blood to the brain its nutrition and functional efficiency may gradually be restored. The possibility of this result and the time required for its attainment will depend on various conditions. There must be a capability on the part of the heart to resume its control over the circulation; it must not be degenerate or worn out. The state of the cerebral arteries, again, will have an important influence; if they are extensively diseased, the access of blood to the convolutions may be barred even when the circulation elsewhere is good. Further, the change in the nervous elements must not have gone too far; the longer they have been subjected to the deteriorating influence of imperfect blood-supply, the longer will be the time required for the reversal of the effects. Of these three sets of conditions we can only estimate the first by examination; with regard to the others, the basis of our judgment must be the history. Speaking generally, the more acute the attack and the shorter its duration, the better will be the chances of recovery.

Cases of this kind, many of which have come under my notice, do not lend themselves to narration, especially when seen in consultation only once or twice, and I shall not attempt to bring instances before you. I may, however, relate an occurrence with regard to one such—a most distressing case of religious melancholia in a lady of about sixty, with extreme high tension in the pulse. I had explained my views to Dr. Baines, with whom I saw the patient, and had recommended, among other measures, a series of mild calomel purges, when the sister of the patient joined us, in order to learn our opinion. Before hearing this, however, she said there was one more fact which she ought to have told us—namely, that their mother, at very nearly the same age, had suffered exactly in the same way. It seemed as if my hypothesis of the relation of the melancholia to the state of the circulation was at once overthrown, and with it my favourable prognosis. "But," she continued, "in those days they gave calomel for everything; and it was prescribed for her, and she got quite well." Our patient also recovered—only, however, to relapse some time later. Melancholia associated with extremely low pulse tension has, in my experience, usually proved incurable, and has in several instances gone steadily from bad to worse to a fatal termination. The case related a few minutes ago is the only instance of recovery I have met with.

I announced that this lecture would be devoted to the pulse and cerebral affections, but I may be permitted to refer to an affection of the lower end of the spinal cord, especially as it furnishes a sort of parallel to the production of melancholia by derangement of the circulation. Our late colleague, Dr. Moxon, whose loss those who knew him well will never cease to deplore, pointed out in his brilliant and original Croonian lectures, six years since, that common paraplegia, as he called it, was explained by anatomical facts. The spinal cord receives its blood-supply by means of the arteries which reach it along the nerve roots. These, in consequence of the downward elongation of the spinal canal beyond the cord, get the more oblique and longer from above downwards, and at the cauda equina are many inches in length, so that the arteries of the lumbar enlargement, which occupies the lower part of the dorsal division of the spine, have to travel upwards for this distance from the foramina in the lumbar and sacral regions. When, then, the circulation becomes languid, the mechanical difficulties of this arrangement make themselves felt. The symptoms attending the early stage of paraplegia due to failing circulation in the lumbar enlargement of the cord are very interesting. As the nutrition of the lower end of the cord begins to suffer, there is at first muscular weakness and loss of control over the legs only after a night's rest. The patient has some difficulty in standing and walking steadily when he first gets out of bed, but after he has moved about a little the legs regain power and he can walk perfectly. A similar state of things is observed with regard to the bladder. He cannot pass urine on rising, but when he has had a little walking he empties the bladder easily. Whenever he sits down for any length of time during the day, there is more or less impairment of mobility and strength in the lower extremities, which quickly passes off with movement. Sensation is not affected at first, but there may be feelings of numbness. The coming on of the weakness during the night is due to the slackening down of the circulation, which takes place during sleep, and is paralleled by the morning depression in melancholia and debility. I have met with this train of symptoms at the two extremities of high and low pressure. When there is high pressure, it is that the general resistance in the periphery has overtaxed the powers of the heart, so that the whole circulation is sluggish, and the languid flow is most easily brought to a standstill where the difficulties are greatest. Usually the symptoms come on very gradually, but I have known their onset to be determined by the occurrence of acute dilatation of the heart. When the tension is low and the heart weak, no explanation of the impeded circulation is needed.

I end these lectures with a feeling that I have done but scanty justice to the subject, but with feelings also of gratitude for the patience and indulgence with which my poor attempt has been received.

Lectures
ON THE
SURGICAL TREATMENT OF PULMONARY CAVITIES.

Delivered at the Consumption Hospital, Brompton,

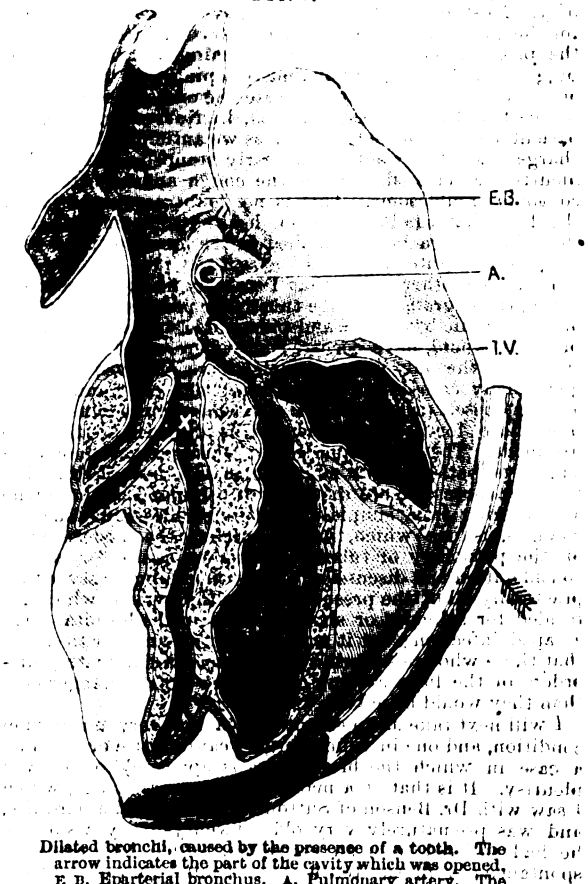
By RICKMAN J. GODLEE, M.S., F.R.C.S.,
SURGEON TO THE HOSPITAL AND TO UNIVERSITY COLLEGE HOSPITAL.

LECTURE II.

(Concluded from page 670.)

THE next case is that of an unfortunate man, aged forty-seven, admitted under the care of Dr. Symes Thompson in February, 1882, who went to a dentist three months previously to have the third left lower molar removed. The elevator slipped, and the tooth dropped into his mouth and by a sudden gasp was drawn into the trachea. He noticed nothing for ten minutes; then there was sudden dyspnœa, lasting for a few minutes, and pain above the right nipple—that is, not far from the level of the angle of the scapula or the seventh dorsal spine. This passed away, leaving a paroxysmal cough, which never afterwards ceased. He began to expectorate thin, frothy mucus with flocculent masses, in amount about half a pint in the day, and continued to do so from that time. He gradually lost flesh, and occasionally suffered from night sweats and flushes; his appetite failed, and he became weaker and weaker. About a fortnight after the accident he felt a tearing pain during a fit of coughing near the right nipple, and for a short time the sputa were tinged with blood; but henceforward he had nothing to indicate the position of the tooth. He was, on admission, emaciated and weak, with rigid arteries and marked arcus senilis, a pulse of 120, respiration 30, and dyspnœa on the slightest exertion; profuse expectoration, especially in the morning; and a troublesome cough, aggravated by any exertion. There was no hæmoptysis. The physical signs were those of emphysema in the left lung and in the upper part of the right. But on the right side, below a line drawn at the level of the angle of the scapula, there was comparative dulness, both in front and behind, with diminished vocal fremitus and resonance. The breathing was weak in front and in the axilla, but behind there was cavernous breathing, with metallic tinkling and pectoriloquy and bronchophony. Pleuritic friction was heard in several places. The heart's apex was not displaced. On March 2nd Mr. Marshall introduced a trocar and canula into the lung at a point two inches from the spine in the eighth interspace, and on this obtaining easy access to cavity that some hard substance was touched, but nothing [illegible]

Digitized by Google



through the cannula. The intercostal space was then opened and the lung incised, causing considerable hæmorrhage and some hæmoptysis. A space was thus reached through which a probe passed an indefinite distance, no doubt having entered a large bronchus. The opening was still further dilated, but nothing came of it, and the wound was first plugged with carbolic acid gauze and then dressed antiseptically. The effect of this operation was to diminish the expectoration to a certain limited extent, while a considerable quantity of pus escaped from the wound and air was forcibly expelled from it when the patient coughed in the way which is characteristic of a freely opened bronchus. A further examination, causing considerable hæmoptysis, was made on May 29th, but without success, and the patient was sent to Eastbourne. By November 14th the wound was completely closed, the drainage-tube having been gradually shortened since the month of August. The physical signs had scarcely if at all altered since the last note. On Dec. 11th he expectorated eight ounces of blood, and this was followed by several similar attacks. It must be remembered, as we shall see in other cases, that patients with bronchiectasis are liable to copious hæmoptysis—a fact that must be taken into account in judging of the effects of surgical interference. In February, 1885, he was readmitted with the following changes in the physical signs:—Loud harsh rhonchi were heard all over both lungs, and there was increased resistence on the left side. This no doubt indicated an extension of the bronchial dilatation, and probably the commencement of the tubercular changes which were found post mortem. During the preceding three months he had become much worse; the wound had reopened and there was a copious discharge of pus, although the expectoration still continued in large quantities (from seven to eight ounces); for several days in December he had suffered from profuse hæmoptysis (half a pint at a time). On Feb. 18th, Mr. Marshall being present, I excised a portion of the ninth rib, so as to make a thorough examination. We found a long cavity with remarkably smooth walls, from which little or no hæmorrhage took place, even after prolonged manipulation. At one part of the cavity a small opening was found, through which a probe could easily be passed a long distance into the bronchus. It impinged against some very large vessel when introduced to its furthest limit. No foreign body was discovered. The expectoration diminished for a few days, and then increased again to its usual quantity. On April 2nd I made several punctures into the lung with the object of finding a second cavity, but without success, accurate diagnosis being out of the question owing to the presence of universal loud rhonchi. The patient gradually became worse, and died on April 16th.

At the post-mortem examination somewhat advanced tubercular changes were found in both lungs, and there was a tubercular cavity at the right apex. The bronchi in the lower parts of both lungs were dilated, but this was especially the case on the right side. Here, then, was a complicated system of dilated bronchi, internal to and below the cavity which communicated with the external wound. Just below the point of bifurcation of the bronchus (Fig. 5, 1 v.) going to this system of cavities the tooth was impacted, riding on the bronchial spur with the fangs downwards. There was no ulceration of the bronchial mucous membrane at the spot, or indeed anywhere; and, as far as could be judged, this was the only spot at which the tooth had lodged. There was slight tubercular ulceration of the cæcum.

This case illustrates very well the nature of the changes which are produced by a foreign body in a bronchus, and appears to show that the changes are brought about by the retention of the irritating, because putrid, secretion; for similar changes have occurred in the lower part of the opposite lung, no doubt because some of the pus found its way into the opposite bronchus. Whether this result is produced wholly or chiefly by the direct action of the secretion upon the bronchi, and whether the contraction of the chronically inflamed lung which surrounds them has much or little to do with the process, it is not easy to say; but it is interesting to notice how close is the resemblance between the condition of this lung in which the mischief is artificially produced, and other specimens in which it has occurred spontaneously. In the earlier stages of a case of this kind there are so few physical signs, and in the later ones there are so many—that is, the loud metallic rales and more or less cavernous breathing are so universal—that it is a matter of very great difficulty to diagnose the position of the foreign body. I do not say that an attempt should not be made to find it. In this particular instance an incision a little further inwards would most likely have led to its discovery; but I do think it is a question, when the history is pretty clear, whether methodical inversion of the patient should not be practised first, and whether, if this be not successful, tracheotomy should not be performed in order that a search may be made with a loop of silver wire suitably bent, or a pair of very delicate curved forceps. With such an instrument I have, without much difficulty, removed a vulcanite tracheotomy tube which had separated from its shield, on the third day I think, after it had become impacted in the right bronchus, and after definite physical signs rendered its presence there indubitable.

From what I have pointed out about the position of the bronchi and their mode of subdivision, it is most likely that the foreign body, if it be as large as a tooth, will be found somewhere in the course of the main right bronchus, and

FIG. 5.

Dilated bronchi, caused by the presence of a tooth. The arrow indicates the part of the cavity which was opened. E. B. Eparterial bronchus. A. Pulmonary artery. The tooth lodged just below the first ventral branch (1 v), in the main bronchus, at a spot marked x.

it is highly likely that the loop of silver wire would bring it up. Any search such as we made in this case must be very problematical unless a gangrenous abscess has formed, and I think we should not wait for such an occurrence. If, as happened in this case, the wrong bronchus is opened, the search from below is of course hopeless; from above, on the other hand, the wire might, by giving it a somewhat different curve, be made to enter many of the lateral bronchi in succession, and at last reach the right one. This plan should be adopted, even after some time, as Dr. Coupland's case shows that recovery may take place after considerable changes have occurred in the lung.

We much hope that such a result will be obtained in the case of H. G——, a woman fifty years of age, now in the hospital under the care of Dr. Williams. She has been the subject of winter cough for years; but has had a severe accession to it since she "swallowed" a piece of mutton-bone about May 19th, 1885. She developed a most troublesome cough after this, with copious fetid expectoration, and at

Digitized by Google

last, after pleurisy on the right side, a collection of pus was diagnosed on the right side and opened by me on Aug. 14th beneath the eighth rib near the angle of the scapula. The abscess only reached the surface at a very limited area, and the finger passed into a sort of sinus, which just held it, about four inches long. For weeks this patient was very little relieved by the operation; the discharge was copious, and expelled with the characteristic whiffing sound referred to before; but the expectoration was scarcely diminished in amount, or at least the diminution was taking place very gradually, and the cough was always very trying. Latterly she has developed a left pleurisy. If it had not been for this I should have undertaken a new exploration. We had not till lately paid proper attention to the history, or had perhaps thought that we had sufficiently often been deceived to warrant us in neglecting "the cry of wolf"; but I was beginning to think whether it might not be right to suggest tracheotomy and search from above, or at least inversion of the patient—a not very simple matter, by the way, in the case of a woman of fifty. Most fortunately, however, whilst we were waiting for the pleurisy to subside, she succeeded in coughing up the piece of bone, and we are watching with interest the progress of the case, and anxiously hoping that the mischief on the other side does not indicate the onset of septicæmia. [Since this lecture was delivered, in November, 1886, the patient has not made the progress we anticipated; the discharge from the wound has nearly stopped, and the left pleurisy has cleared up; but the cough and expectoration continue troublesome. This is no doubt accounted for by the fact that the lung was not healthy to begin with, and that the foreign body remained in the bronchus for a very long time—eighteen months.]

There is another point that I scarcely like to touch upon—viz., the engrafting of the tubercular processes on the top of the chronic bronchitis and pneumonia. This might, and probably would, have occurred anywhere, and I should add that it is the only instance that I have observed out of a good many cases of bronchiectasis; but one cannot help asking oneself whether an institution such as ours is the best place for a patient with this disorder to take up his abode. The whole question of the aggregation of consumptive patients, but more especially that of bringing together those who are distinctly tubercular and those who are suffering from simple—i.e., non-specific—inflammatory changes, is one which, in my opinion, the modern view of the pathology of tubercle opens up again for mature consideration and discussion. It is one thing to show that practically all of the presumably healthy persons who have resided for a longer or shorter period in the hospital have escaped infection; but it would be quite another to assert that those who are suffering from chronic inflammatory disorders of the lung are not exposed to greater danger here than they would be outside.

I will next take as an example of a not very uncommon condition, and one in which surgery can do little or nothing, a case in which the bronchiectasis appeared to follow a pleurisy. It is that of a man fifty-five years of age, whom I saw with Dr. Benson of Sutton. He had lived a hard life, and was prematurely very old. Twenty-five years before he had suffered from an empyema, which had ruptured spontaneously in the tenth space behind (a very unusual position for such an occurrence), and, after discharging for four weeks or so, had healed. Since this time he had always been liable to cough, especially during the winter, which during the last few years had been much worse, causing a gradual decline of the patient's health. There was at the time very copious purulent expectoration, as if from a cavity, and there were also much emaciation and marked clubbing of the fingers, but there was no albuminuria. The left side of the chest was contracted, resonant in front, with harsh breathing and creaking and sonorous râles, but almost dull in patches over an area corresponding to the lower lobe in the back and axilla; there was no absolute dulness, however, and none in front of the mid-axillary line. Over this area of defective resonance there was amphoric breathing with metallic râles, and pretty well marked ægophony and pectoriloquy were heard in places. The right side was resonant throughout, with harsh breathing and sibilant and sonorous râles. The heart was drawn a little outwards, and there was no murmur, though previously one had been heard which was thought to be tricuspid. An incision had been made a few days before in the tenth space, and a little doubtful pus had been seen; if so, the knife had no doubt reached one of the dilated bronchi, for it must be remembered that in these cases, even if cavities do exist and are the source of the greater part of the expectoration, the bronchi contain a precisely similar material. The diagnosis was extensive bronchiectasis throughout the lower lobe of this lung, but probably no distinct cavity. The case seemed a most unpromising one for operation, not only on account of the supposed state of the lung, but also from the patient's general condition. A trocar was, however, introduced at the spot where the amphoric breathing was most marked—viz., in the eighth interspace behind. It was passed in for two inches and entered condensed lung, but did not reach any cavity, and no hæmoptysis followed. The patient lived three days longer, and Dr. Benson sent me the notes of the necropsy. They show that the right lung and the anterior part of the left lung were partly emphysematous, partly marked by old cicatricial contractions, and that there were in these regions old scattered firm adhesions; but the lower two-thirds of the left lung were bound down by universal and very strong old adhesions three-sixteenths of an inch or more in thickness, and this part was "firm and consolidated, tough and cartilaginous on section. The section was studded with the open lumina of the bronchial branches; the bronchial walls were everywhere very much thickened and at places very much dilated, their mucous membrane being thickened and injected; the bronchi contained blood-stained muco-pus. No actual cavities were found." The liver was nutmeg, and the heart somewhat fatty.

One cannot doubt that the old pleurisy, with perhaps some pneumonia, was in this case the cause of the commencement of the process. It is remarkable to me that it was so much confined to the lower lobe of this lung; but, notwithstanding its local nature, it is not apparent in what way surgery could at any time have been of use. In exploring the lung in cases like this, when contraction may be presumed to have occurred, it is important not to go beyond the natural limit of the lung downwards; and, indeed, it is wiser to stop short of this. This part of the lung behind is very thin, and an incautious use of the trocar might readily lead to the puncture of the peritoneal cavity, or perhaps of some abdominal viscus.

I will now pass to a few cases which are instructive as illustrating the difficulties and some of the dangers which attend the attempts at dealing with more or less diffused cases of bronchiectasis. I will take, in the first place, one in which nothing was done except an exploratory puncture, but in which the mere administration of the anæsthetic led to a fatal result; it is highly instructive as illustrating the fact that the amount of the physical signs is no criterion of the amount of mischief present. In this case, for example, they showed little or no mischief on the right side, though the man's general condition led us to suspect that this lung was not sound. We found, indeed, that the mischief was almost, if not quite, as advanced as on the other.

R. N——, aged thirty-five, a man of fair general health, who had all his life been the subject of a slight cough, was admitted under the care of Dr. Powell. He had suffered from syphilis ten years before, had been a hard drinker, but had not been troubled much with his chest until about a year previously, when he had an attack of hæmoptysis following apparently on severe exertion, since which time the expectoration, which had been more copious, gradually became offensive. Shortness of breath for three months had distressed him very much. The man was in a very feeble condition, with clubbed fingers and some general blueness, and obvious dyspnœa; a peaky temperature, varying from normal to 102°, and a pulse of about 130. Briefly to sum up his physical signs, they appeared to point to a considerable coalescence of bronchiectatic cavities over the lower part of the left scapular region and at the apex behind, but did not indicate much amiss with the right side. Neither Dr. Powell nor I anticipated much benefit from surgical interference, but it was thought right to make an exploration with the view of determining whether or not there was a cavity large enough to deal with. Accordingly, on Sept. 4th, 1885, chloroform was administered. He took it badly; he was in a highly nervous condition and coughed considerably, emptying his dilated bronchi—which, as it turned out, were very numerous—into the larger air tubes. The result was that he became exceedingly blue and perspired freely. Not much chloroform was administered. Two punctures were made without effect, and then we found that all our attention was needed in order to

Digitized by Google

attempt to clear the bronchi. Our efforts, however, were not successful. It was not exactly a case of death from chloroform, for his state was at first not so very alarming; the act of respiration was performed freely enough, even forcibly, but there were loud tracheal râles, which gradually increased. He lived in this state for half an hour, and then, notwithstanding all our attempts to aid him to cough, he became completely choked by the pus which he had partly coughed and partly vomited up. Post mortem, the cavities which had been diagnosed were discovered in the position indicated by Dr. Powell; the whole of both lobes of the left lung being dense and tough, with markedly fibrous interlobular septa. But the right lung also, though spongy, was throughout the subject of bronchial dilatation, not indeed so marked as on the opposite side, but still, when it is said that one cavity was as large as a hen's egg, it will be recognised that the disease was considerable.

From the surgical point of view, one is struck with the fact that this patient was supposed to have but little the matter with the right lung, whereas it contained several cavities of considerable size; and also with the fact that, although the cavity to which the surgeon's attention was specially directed was undoubtedly the largest, still there were others at some distance from it in the same lung not much inferior to it in size. These cavities all present the glistening, smooth-walled appearance which seems to be typical of these excavations; they have strands and bars of fibrous material crossing them, which apparently contain vessels, resembling the columnæ carneæ of the heart. They seem often to be continuations of the main bronchi, but are not always so, for one in the left lung is separated by at least an inch from the main bronchus, and communicates with it by quite a small tube.

I cannot leave this case without making an observation on the subject of the anæsthetic. Ether would in many of the cases we are dealing with be the natural drug to give, because the heart is often acting so feebly, were it not for the impairment of the respiration which is frequently caused by it, owing to the copious secretion of mucus. Besides which, it is more apt than chloroform to induce cough, and coughing increases not only the surgeon's difficulties by emptying the cavity, but also the patient's danger, as in this case, by blocking up the healthier bronchi. A little while ago we were giving ether to a man the right side of whose chest was distended with pus. His heart's action was already much interfered with, and he struggled and coughed violently during the early part of the administration; the result was that he passed into a state of imminent danger. He became cyanotic, the right side of the heart was engorged, the pulse was beginning to fail and the pupils to dilate, though he had taken but little of the anæsthetic. If the pleura had not been immediately opened, I do not think that this patient would have recovered from the condition set up by this really very small dose of ether. There are many cases, however—small empyemata, with comparatively healthy lungs,—where it may quite safely be employed. Chloroform does not usually make the patient cough so much, though it is necessary in many cases to give the anæsthetic very slowly in order to obtain this result; but, on the other hand, it weakens the heart action. Hence it will be understood that occasionally cases may be met with in which it is not safe to give any anæsthetic at all. An empyema may easily be opened without causing any great pain if the cellular tissue of the part has been injected with cocaine; but in a case of pulmonary abscess the anæsthesia produced by this drug would be too limited and too transient. On the whole, therefore, in the greater number of cases, chloroform, given slowly and with great caution, seems to be the safest anæsthetic at our disposal.

Of course, in all cases of puncture of or incision into the lung, it will be remembered, as I stated in the first lecture, that the same danger may at any moment arise from the escape of blood into the bronchi; hence it is well never to have the patient so deeply anæsthetised that the natural relief of coughing for such a catastrophe cannot be obtained. A typical example of this class of cases formed the subject of a paper by Dr. Williams and myself at the Medico-Chirurgical Society last session,[1] and will therefore be only briefly referred to here.

Mary [illegible], aged twenty-one, a domestic servant, was admitted into the Brompton Hospital in May, 1885, with chronic bronchitis and emphysema of both lungs, followed [illegible]
